THE Duke of Westminster was present at the Westminster Hospital at a reception which was held on November 1st to celebrate the reopening of the hospital, which has undergone extensive renovation and some very important improvements. The cost of the improvements had been large, but an appeal was issued, and the response made was most liberal. In all upwards of £5,200 had been received, which covered the extraordinary expenditure; at least £200 was in the form of annual subscriptions. The Duke of Westminster congratulated the supporters of the hospital on the improvements effected.

THE autumnal meeting in connection with the Earlswood Asylum for Idiots was held on October 31st, for the purpose of electing forty applicants, when it was reported that the institution continued to make steady progress. Many of the pupils had developed an aptitude for learning that was scarcely anticipated, and those in the workshops and on the farm had rendered most useful service. The majority of the cases received were much benefited, and many of them were taught useful trades. The basket making lately introduced into the girls' school had turned out a great success. All the shops continued to do good work, many of the pupils being self-supporting while under supervision. During the winter, dances, minstrels, concerts, variety entertainments, and schoolroom parties had been the chief sources of entertainment, and an orchestra had been organised.

THE International Sleeping Car Company have made the following arrangements for the winter season in the South of France: 1. The Calais Mediterranean express will be re-established, and will run every Thursday (commencing November 7th) in connection with the 9 A.M. service from London (Victoria and Charing Cross), calling at Marseilles, Cannes, Nice, Monte Carlo, Mentone, etc., reaching Vintimille at 12.35 P.M. the following day. Baggage will be registered through to destination and examined *en route*. This train will be composed entirely of the company's sleeping and dining cars. 2. A Mediterranean express will also leave Paris (P. L. M. Station) every Tuesday and Saturday at 5.30 P.M., reaching Vintimille at the same time as Thursday's train from Calais. 3. The Nice express will leave Paris (Gare du Nord) at 7.44 P.M. daily, to which, between the Nord and Lyons Stations, a restaurant car will be attached. 4. The *Rapide* will leave Paris (Gare de Lyon) for the Riviera every evening at 8.25. Through tickets, single and return, are to be obtained at the company's offices at 14, Cockspur Street, S.W., where places must be reserved in advance.

MEDICAL VACANCIES.

The following vacancies are announced:

- BROWN ANIMAL SANATORY INSTITUTION.**—Professor Superintendent. Salary, £200 per annum. Applications to the Registrar of the University of London, Burlington Gardens, W., by November 15th.
- CLIFTON DISPENSARY,** Doury Square, Bristol.—Resident Medical Officer; not exceeding 30 years of age; doubly qualified. Salary, beginning at £150 a year, increasing annually by £10 to £200, with furnished rooms only. Applications to R. C. Macfie, 42, Royal York Crescent, Clifton, Bristol, before November 23rd.
- COUNTY DOWN INFIRMARY,** Downpatrick.—Registrar, Compounder of Medicine, and Assistant to the surgeon. Salary, £65, with board, fuel, and washing. Applications to Dr. Tate by November 14th.
- DENBIGHSHIRE INFIRMARY,** Denbigh.—House-Surgeon; must be duly qualified to practise medicine and surgery, and be conversant with the Welsh language. Salary, £80 per annum, with board, residence, and washing. Applications and testimonials to W. Vaughan Jones, Secretary, by December 2nd.
- GENERAL HOSPITAL,** Birmingham.—Assistant House-Surgeon. Appointment for six months. No salary, but residence, board, and washing provided. Applications to Howard J. Collins, House Governor, by November 30th.
- GENERAL HOSPITAL,** Northampton.—House-Surgeon; doubly qualified; unmarried, and not under 23 years of age. Salary, £120 per annum, with furnished apartments, board, attendance, and washing. The Assistant House-Surgeon is a candidate, and, if appointed, the Committee will proceed with the election of Assistant House Surgeon. Salary, £60 per annum, with furnished apartments, board, and attendance. Applications to the Secretary by November 23rd.
- HANTS COUNTY ASYLUM.**—Third Assistant Medical Officer; doubly qualified; age must not exceed 25 years, and must be unmarried. Salary, £100 per annum, increasing to £125 after twelve months' service, with furnished apartments, board, washing, and attendance.

Applications, endorsed "Application for Appointment of Medical Officer," to the Committee of Visitors, Knowle, Fareham, by November 30th.

KILBURN, MAIDA VALE, AND ST. JOHN'S WOOD GENERAL DISPENSARY.—Vacancy on the Honorary Medical Board. Applications to the Secretary by November 10th.

NATIONAL HOSPITAL FOR DISEASES OF THE HEART AND PARALYSIS, 32, Soho Square.—Resident Medical Officer. Appointment for six months. Board, residence, laundry, and an honorarium of 10 guineas; doubly qualified. Applications to the Secretary by November 15th.

NEW HOSPITAL FOR WOMEN, 144, Euston Road.—Two Qualified Medical Women as House-Surgeons. Applications to Margaret M. Bagster, Secretary, by November 27th.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City Road, E.C.—House-Physician. Appointment for six months. Salary at the rate of £40 per annum, with board and lodging. Applications to the Secretary by November 14th.

ROYAL PORTSMOUTH HOSPITAL.—Assistant House-Surgeon: appointment for six months. Honorarium of £15 15s., and board and residence, and is renewable for a further period of six months. Applications and testimonials to J. A. Byerley, Secretary, before November 10th.

ROYAL SOUTH HANTS INFIRMARY, Southampton.—Assistant House-Surgeon. Appointment for six months. Gratuity of £10. Applications to T. A. Fisher Hall, Secretary, by November 16th.

ST. MARY'S HOSPITAL FOR SICK CHILDREN, AND MEDICAL MISSION DISPENSARY FOR THE POOR, Plaistow, E.—Resident Medical Officer; doubly qualified. Salary, £200 per annum, with board, washing, and attendance. Applications to the Chairman of Committee, the Rev. T. Given-Wilson, M.A., Vicar of Plaistow, London, E.

TIVERTON INFIRMARY AND DISPENSARY.—House-Surgeon and Dispenser; registered and unmarried. Salary, £105 per annum, with lodgings, attendance fire, and lights. Applications to Arthur Fisher, Honorary Secretary, by November 26th.

VICTORIA UNIVERSITY, Manchester.—External Examiner in Pharmacology and Therapeutics and in Surgery. Appointment for three years. Applications to Alfred T. Bentley, Registrar, by November 26th.

WEST NORFOLK AND LYNN HOSPITAL, King's Lynn.—House-Surgeon. Salary, £80 per annum, rising £10 annually to £100, with board, residence, and washing. Applications to the Secretary by November 22nd.

MEDICAL APPOINTMENTS.

BROWN, John, M.D. Vict., D.S. Sci., reappointed Medical Officer of Health for the Borough of Beapou and Physician to the Southall Fever Hospital.

BURNETT, W. E. S., L.R.C.P., L.R.C.S. Edin., appointed Medical Officer of Health to the Tintwistle Rural Sanitary District.

CLENDINEN, William McEntire, M.R.C.S., L.R.C.P. Lond., appointed Medical Officer of Health to the Cosley Urban District, *vice* J. J. Clendinnen, L.R.C.S.I., deceased.

COOKE, Mr. T., appointed Medical Officer of Health to the Limehurst Rural District Council.

DUMMERE, Howard H., L.R.C.P. Lond., M.R.C.S. Eng., reappointed Medical Officer for the No. 4 District of the Bromley Union.

EDWARDS, N. F., M.B., Ch.B. Vict., appointed Assistant House-Surgeon to the Swansea Hospital.

FENN, Robert M., M.B. C.M., appointed Honorary Assistant Physician to the Manchester Hospital for Consumption and Diseases of the Throat and Chest.

FRASER, Peter, M.D., B.Sc., appointed Medical Officer of Health to the Carnarvon Joint Sanitary Authority.

GIBSON, D., M.R.C.S. Eng., L.S.A., reappointed Medical Officer for the North Mynton District of the Hull Union.

HALL, Dr. Alfred, appointed Medical Officer of Health to the Mayfield Rural District.

JACKMAN, J. J. H., L.R.C.P., L.R.C.S.I., appointed Medical Officer for Watford Workhouse and Fever Hospital, *vice* P. J. Whitty, M.R.C.P.I., L.R.C.S.I.

JAMES, Philip, F.R.C.S., appointed Surgeon to the Wellington Hospital, New Zealand.

KRIFFENHEIM-TRUBIDOR, I. W. A., M.D. Durh., M.R.C.S., L.R.C.P., appointed Medical Officer of Health to the Hoo Rural Sanitary District, *vice* A. G. A. Packman, M.D. Durh., M.R.C.S. Eng.

KNAPP, E. M., L.R.C.P. Edin., M.R.C.S. Eng., appointed Medical Officer for the Aston, Ingham, and Linton Districts of the Ross Union.

LEWIS, C. E. M., M.A., M.B., B.C. Camb., appointed Assistant Resident Medical Officer to the North-West London Hospital.

LIGHTWOOD, C. E., M.B., B.Ch. Vict., appointed one of the House-Physicians to the General Infirmary, Leeds.

LITTLEJOHN, Herbert, M.B., D.P.H., C.M., appointed Medical Officer of Health for Scarborough, *vice* H. G. H. Monk, M.R.C.S. Eng.

MCKENZIE, A., B.A. Cantab., M.R.C.S., L.R.C.P., appointed one of the House-Surgeons to the General Infirmary, Leeds.

MACNIDDER, James, M.B., C.M. Edin., appointed Medical Officer for the Town District of the Hull Union.

MORRIS, Dr. H., appointed Medical Officer for the Silverdale District of the Tanstall Union.

MORRIS, T. H. P., M.R.C.S., L.R.C.P. Lond., appointed House-Surgeon to the Stourbridge Dispensary.

NICHOLSON, J., M.R.C.S., L.R.C.P., appointed Resident Medical Officer at Ida Hospital of the General Infirmary, Leeds.

OLIPHANT, Frank, M.B. Edin., appointed Senior House-Surgeon to the Chesterfield and North Derbyshire Hospital, Chesterfield.

PHILLIPS, E. V., L.R.C.P. Lond., M.R.C.S., appointed Medical Officer of Health to the Oxenden Rural Sanitary District, vice T. Macaulay, M.R.C.S., resigned.

POWELL, Dr., appointed Medical Officer of Health to the Llandyssul Rural District Council.

RICHMOND, R., M.D., appointed Medical Officer of Health to the Dunmow Rural Sanitary District, vice B. Ronald, resigned.

STEWART, E. S., M.R.C.S., L.R.C.P., appointed Resident Ophthalmic Officer to the General Infirmary, Leeds.

STOTT, W. A., appointed Pathological Curator to the General Infirmary, Leeds.

TAIT, A., M.B. Lond., appointed Resident Obstetric Officer to the General Infirmary, Leeds.

TIBBETTS, Dr., appointed Medical Officer of Health to the Quarry Bank Urban District Council.

TRETHOWAN, William, M.B., C.M. Abard., appointed Honorary Assistant Surgeon to the General Hospital, Perth, West Australia.

TRIM, A. Gladstone, L.S.A., appointed Surgeon of the Abergorky and Yafwen Collieries, Rhondda Valley, vice E. C. Joyce, M.B., resigned.

TROTT, R. H., M.B., B.Ch. Vict., appointed one of the House-Surgeons to the General Infirmary, Leeds.

TWOME, John L., L.R.C.P., L.R.C.S. Edin., appointed Medical Officer for the Golden Dispensary, Leeds.

WHITE, O. M., M.R.C.S. Eng., L.S.A., reappointed Medical Officer for the No. 6 District of the Bromley Union.

WILSON, A., L.R.C.P., M.R.C.S. Eng., reappointed Medical Officer for the South Mynton District of the Hull Union.

WOODCOCK, Arthur Ernest, L.R.C.P. & S.E., appointed Certifying Factory Surgeon, vice M. E. B. Nicholson, M.R.C.S., L.S.A., deceased.

WRAT, G. B., M.R.C.S. Eng., L.S.A., D.P.H., appointed Medical Officer of Health to the Basford District Council.

DIARY FOR NEXT WEEK.

MONDAY.

LONDON POST-GRADUATE COURSE, London Throat Hospital, Great Portland Street, 8 P.M.—Dr. Whistler: Tuberculosis of the Larynx.

MEDICAL SOCIETY OF LONDON, 8.30 P.M.—Clinical Cases. Dr. Sansom: Addison's Disease treated by Suprarenal Extract. Mr. Harold: Congenital Feeble-mindedness associated with Congenital Deficiency of the Chest Wall and with Cardiac Disease. Mr. Wallis: (1) Wired Patella for Fracture in a Man aged 70; (2) Compound Comminuted Fracture of the Skull with Facial Paralysis. Dr. L. Guthrie: Spina Bifida Occulta with Paresis of Leg; (3) Postero-lateral Sclerosis. Mr. S. Edwards: Case after Nephrectomy for Injury, with Specimen. Dr. Savill: Cases of Telangiectasia. Mr. S. Boyd: Temporary Resection of Upper Jaw for Nasopharyngeal Growth.

TUESDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 2 P.M.—Dr. Craig: Impulsive, Homicidal, and Moral Insanity.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M., Lecture at 4.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, 5 P.M.—Dr. J. B. Bradbury: The Bradshaw Lecture on Some New Vaso-dilators.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8.30 P.M.—Dr. Frederic Hewitt and Mr. A. M. Sheild: On Posture in its Relation to Surgical Operations under Anesthetics (Adjourned discussion). Dr. R. A. Gibbons: Renal Colic in Infants.

WEDNESDAY.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. Maguire: On Hemoptysis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 3 P.M.—Lecture by Dr. Gowers.

HUNTERIAN SOCIETY, 8 P.M.—Clinical evening. Mr. W. Campbell McDunnell: Case of Congenital Ataxia. Mr. Targitt: Excision of Temporo-maxillary Joint in a Child. Dr. Sequerra: Nystagmus. Dr. Oliver Lyon: Imperfectly developed Pons. Dr. Fred. G. Smith: Paroxysmal Hemoglobinuria with Local Asphyxia. Mr. Hugh Beaver Bart: Cases of Cervical Herpes and of Retrauded Lung in a Boy of 4. Dr. Elliot: Cases of Distension of Left Frontal Sinus, and of Horizontal Nystagmus.

WEST LONDON HOSPITAL, Hammersmith, W., 5 P.M.—Dr. W. A. Turner: Neurological Cases (Post-Graduate Course).

LARYNGOLOGICAL SOCIETY OF LONDON, 30, Hanover Square, W., 5 P.M.—Cases, Specimens, etc., will be exhibited by Dr. J. B. Hall, Dr. F. W. Bennett, Mr. A. A. Rowley, Dr. A. Brummer, Mr. H. T. Butler, Dr. Wm. Hill, Dr. A. A. Kanthack, Dr. Percy Kidd, Dr. Edward Law, Dr. Scanes Spicer, and Mr. W. K. H. Stewart.

SOUTH-WEST LONDON MEDICAL SOCIETY, 335, Lavender Hill, 8.30 P.M.—Dr. Chas. W. Chapman on Heart Disease in the Young; its Management and Treatment. At 9 P.M. Dr. Chapman proposes, if possible, to show patients illustrating his paper.

THURSDAY.

LONDON POST-GRADUATE COURSE, Hospital for the Paralyzed and Epileptic, Queen Square, 2 P.M.—Dr. Taylor: Syphilitic Involvement of the Nervous System. Hospital for Sick Children, Great Ormond Street, 3.30 P.M.—Mr. John H. Morgan: Cases from the Surgical Wards. Central London Sick Asylum, Cleveland Street, 5.30 P.M.—Dr. W. Hale White: Cases in the Wards.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY, Great Northern Central Hospital, Holloway Road, N., 8.30 P.M.—Clinical evening. Cases will be shown by Mr. Brooke, Mr. Hamilton, Mr. Mower White, Mr. T. P. B. Beale, Dr. E. C. Beale, and Dr. James Galloway.

BRITISH GYNÆCOLOGICAL SOCIETY, 30, Hanover Square, W., 8.30 P.M.—Specimens.—Dr. Elder, Mr. Skene Keith. Papers.—Dr. Elder (Nottingham): The present condition of a Patient operated upon April, 1894, for Double Ovarian Papinoma; also Notes on a Porro's operation. Mr. Skene Keith: Unusual Complications in Two Cases of Removal of the Ovaries. Dr. Haldeney Cross: Glycosuria complicating an Ovarian Tumour and Ovariotomy. Dr. John Shaw: Short note on a Complication impeding the Convalescence of a case of Oophorectomy.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM, 11, Chandos Street, Cavendish Square, W.—Card Specimens at 5 P.M. by Mr. Wray, Mr. S. Stephenson, Dr. A. Brummer, Mr. Hartridge, Mr. Tweedy, Mr. Work Dodd. Papers at 8.30: Mr. W. H. Jessop: Some Cases of Graves's Disease, with Destruction of Eyes. Mr. Chas. Wray: The Treatment of Detachment of the Retina. Messrs. Eales and Sinclair: Case of Uveal Cyst of the Iris.

FRIDAY.

LONDON POST-GRADUATE COURSE, Bacteriological Laboratory, King's College, 3 to 5 P.M.—Professor Crookshank: Lecture: Typhoid Fever and Diphtheria. Practical Work: Staining Sections and Cultivations.

EPIDEMIOLOGICAL SOCIETY OF LONDON, 11, Chandos Street, W., 5 P.M.—Mr. T. W. Thompson: On Considerations in Respect to "Return" Cases of Scarlatina.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, W., 8.30 P.M.—Adjourned discussion on Gastric Ulcer to be opened by Mr. Keetley, Drs. Bennett, Chippingdale, Messrs. S. Edwards, Wharry, Bidwell, and Eccles will take part in the discussion.

SATURDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 11 A.M.—Dr. Craig: General Paralysis of the Insane.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

CHEYNE.—On October 31st, at 75, Harley Street, W., the wife of W. Watson Cheyne, F.R.S., of a daughter.

DEMPSTER.—On November 3rd, at Viewley, Redhill, the wife of J. H. Dempster, L.R.C.P., M.R.C.S., of a son.

HICKLEY.—On October 31st, at 302, South Lambeth Road, S.W., the wife of A. Mackenzie Hickley, L.R.C.P. Lond., M.R.C.S. Eng., of a daughter.

MARRIAGES.

LINNELL-WHITWORTH.—On October 31st, at All Saints Church, Turvey, by the Rev. G. F. W. Munby, Alfred Linnell, of Paulerspury, third son of the late James Edward Linnell, of The Hill, Paulerspury, to Mary Blanche Joanna, younger daughter of the late John Whitworth, of Turvey.

MACMUNN-WERN.—On October 30th, at St. Luke's, Iron Bridge, by the Rev. C. Dunkley, Vicar of St. Mary's, Wolverhampton, assisted by the Rev. George Wintour, Rector, Charles A. MacMunn, M.A., M.D., Wolverhampton, to Susan Bartlett (Sister), third daughter of the late Matthew Webb, M.R.C.S., of Iron Bridge.

SIMPSON-HERRERT.—On November 5th, at St. Mary's Parish Church, Folkestone, by the Rev. Canon Woodward, Vicar of the Parish, James Christian Simpson, M.D. Edin., of Culverden Grange, Tunbridge Wells, son of the Rev. James Simpson, LL.D., former Minister of Dysart, Fife, N.B., to Margaret Primrose, eldest daughter of the late Nicholas Herbert, Esq., South Kensington.

SMITH-ALCOCK.—On October 31st, at St. Paul's Church, Burslem, Staffordshire, by the Rev. Malcolm Graham, Vicar of St. Paul's, assisted by the Rev. N. Edwards, Rector of Burslem, and the Rev. H. S. Ellis, Greenwich, Alfred Thompson Smith, M.B., C.M., of Orpington, Kent, to Catherine Maude King, eldest daughter of J. Alcock, Esq., J.P., Surgeon, Burslem.

DEATHS.

BALL.—On November 6th, at his residence, Mill Creek, York, Alfred Ball, M.R.C.S., aged 69.

NEWBING.—On October 6th, at Willowmere, Cape Colony, of phthisis, Robert Pope Newbington, B.A., L.R.C.S. & P. Edin., eldest son of the late Robert Newbington, of Madras, aged 46 years. Indian papers please copy.

RRAN.—On October 28th, at 19, Richmond Place, Brighton, William Henry Rran, M.R.C.S.E., L.S.A., aged 40 years.

LETTERS, NOTES, AND ANSWERS TO
CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 499, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 499, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 499, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

MR. JAMES H. MILLAR would be glad to have the address of Dr. Impey, of the Paper Settlement, Robben Island, who is at present believed to be in this country.

NEUROSIIS writes: I shall be obliged if any reader of the BRITISH MEDICAL JOURNAL can tell me of a home for a respectable woman in poor circumstances, afflicted with paralysis agitans. She could pay 12s. a week.

A MEMBER would like to know the advantages or disadvantages, as compared with K.I., of the iodide of strontium, from someone who has had experience in the use of the latter drug. Is the iodide as effective specifically as that of K.I.? And how does the strontium compare with the potassium base?

RUS asks for suggestions for the treatment of the case of a gentleman who has been in India many years. He suffers a good deal from gout in his joints, and when these are troublesome the eyes are not so bad. At the present time the conjunctiva of both eyes is inflamed and irritable, constant tendency to rub them; looking at any object makes them much worse; wind, cold, heat, and even exposure to air, start irritation. There are minute eczematous papules and vesicles scattered over face as far as the malar prominence, as high as the middle of forehead, over the eyelids, and down the side of nose, the whole of these parts being slightly moist with discharging serum.

CLIMATE AND CANCER.

DR. PERCY NEWELL (Crowthorpe, Sussex) asks where he can obtain information as to the influence of climate on cancer and cancerous diseases. He has been frequently told by patients that medical men have told them that dry bracing climates aggravate cancer existing already.

DISINFECTION OF TYPHOID STOOLS.

MEMBER asks for reference to a published account of experiments on the relative value of various antiseptics in destroying the infectiveness of typhoid stools.

THE LANCHESTER CASE.

M.B., C.M. writes: After reading Dr. G. F. Blandford's statement in the BRITISH MEDICAL JOURNAL of November 2nd, I should like to ask the following question: Would I or any other doctor be justified in signing an urgent order in the case of a man expressing exactly similar views as Miss Lancheater has done—that is, substitute the word *he* for *she* in the above statement all through?

TREATMENT FOR PSORIASIS.

J. F. D. asks for advice in the treatment of a lady, aged 32, who has been suffering from a chronic form of psoriasis of the fingers of both hands for the last eight years, and it has a tendency to spread upwards. The skin of the affected parts has become cracked, hard, and very rough. The chief complaint is unbearable itching, for which most of the ordinary remedies have been tried without success. There is no constitutional affection of any kind, except that she has had fever for the last two years, especially at night, and various antifebrile remedies have been tried without success.

THE PASTEUR FILTER.

INDEX (Norwich) asks to be referred to a description of the Pasteur filter. He also wishes to know where they are to be obtained.

*The London agents for the Pasteur filter are Dairies, of 147, Houndsditch, London, who could, we presume, furnish the particulars asked for.

ANSWERS.

IF A. T. is incapable of writing his own lectures, we advise him not to give them.

R. W. G.—We have referred our correspondent's letter to Mr. Stephen Paget, who informed us that he has forwarded a copy of the *Records of Harvey*. Mr. Stephen Paget adds that he has several copies of the work, which he would forward to anyone else who wants one.

DR. W. M. K.—We have referred our correspondent's query to Mr. Stephen Paget, F.R.C.S., Secretary of the Association for the Advancement of Medicine by Research, 57, Wimpole Street, W., who will supply the information asked.

SURGEON-MAJOR F. J. LAMBKIN, A.M.S. (Newcastle, Jamaica), writes in reply to "G. J. K.," who, in the BRITISH MEDICAL JOURNAL of June 20th, asked for information relating to hypodermic medication in syphilis, that in the Army Medical Report for 1894 full information will be found in a paper by Surgeon Major Lambkin.

W. P. M.B., writes in reply to "G. P.," in the BRITISH MEDICAL JOURNAL of November 2nd, p. 1142: I would suggest that all pressure due to corset and dress be diminished as much as possible, that the regimen be continued, and that the following modification be adopted: R Aloin gr ij; ferri sulph. gr i; ext. nucis vom. gr i; pulv. iuvrrie gr i; saponis gr i. Ft. pil. i sum. semel. bis vel ter die post cib. inst. And when this pil. is not taken: R Ext. nucis vom. gr i; pulv. myrrhæ q.s. et ft. pil. i.

MR. L. A. BIDWELL, F.R.C.S., Hon. Sec. to the staff of the West London Hospital, writes, in answer to E. H. F.'s query: May I be allowed to state that gentlemen attending the post-graduate teaching at the West London Hospital, will find opportunities of assisting in putting up fractures and reducing dislocations. I shall be glad to supply full particulars.

INJUDICIOUS TESTIMONIALS.

E. H. D.—It is undesirable for a surgeon to state in a testimonial to an assistant that he has often had occasion to consult the assistant about the proper spectacles to use, but the giving of such a testimonial would not, we apprehend, be held to constitute the offence of covering an unqualified practitioner.

SALIVATION IN PREGNANCY.

M.R.C.S. writes: In answer to "E.," in the BRITISH MEDICAL JOURNAL of November 2nd, p. 1142, I would advise liq. arsenicalis mj every fifteen minutes for an hour before leaving the horizontal position in the morning.

ROUND SHOULDERS.

M.D. recommends "A Member," who asked a question on this subject in the BRITISH MEDICAL JOURNAL of November 2nd, to study Roth's book on the *Treatment of Lateral Curvature of the Spine*. Mr. G. Steele Perkins (Wimpole Street, W.) and Mr. Gerard Smith (Gloucester Place, W.) both offer to advise "A Member" privately.

MR. C. E. ABBOTT, M.R.C.S. (Taunton) writes: I would suggest the probability of scoliosis. The rational treatment is careful attention to secure an improved position. This can be attained by regular exercise of the upper part of the trunk and neck, also deep breathing, as described by the writer of an article on Lateral Curvature of the Spine in Heath's *Dictionary of Surgery*, pp. 910-913. Braces and such-like appliances are to be avoided.

FEES FOR INSURANCE CASES.

A. C. writes: Are there any definite rates fixed for examining candidates for life assurance? There is an immense amount of work done of this nature, and I think it is time that some steps were taken to secure a uniform rate. Could not some committee inquire into the matter, and recommend some charges, below which practitioners could be advised to refuse to undertake the work?

*We have referred this letter to Dr. F. de Havilland Hall, who writes: I raised the question of the desirability of having some definite scale of charges for reports in cases of assurance at a recent meeting of the Life Assurance Medical Officers' Association, but it was ruled that the Association was formed for the discussion of subjects relating to the medical aspect of life assurance, and that it could not entertain the question of fees.

I think it would be in the interest of the companies as well as of the medical examiners if a table of fees could be drawn up. The only way to do so in my opinion would be for a representative meeting of the chief medical advisers of the various classes of assurance offices to discuss the matter, and submit their views to their respective directors.

NAIL BITING.

M.D. writes: Though the habit of nail biting is, as Dr. Wilberforce Smith suggests, most often observed in neurotic children, it commonly arises in a physical defect. In most nail biting children it will be found that the nails are unduly thin or brittle, or present both defects. The child is constantly breaking its nails, and then bites them to remove the torn portion. In all cases of nail biting the nails should receive constant attention. They should be kept well trimmed, all ragged edges being smoothed away with sharp scissors at least twice a week. This will not cure an inveterate nail biter, but it will check the formation of the habit, and even in the worst cases will reinforce other means which may be tried.

DORSET writes: For twenty years and more I bit my nails, and then at last got over the trick, but in its place I have acquired the worse, because more painful, habit of finger picking, that is, tearing at the portions of skin around the roots of the nails. The habit comes on me at longer or shorter intervals, and continues until my finger tips are so sore that I am compelled to leave off. I pick the fingers of the right hand far more than the left, and I generally do it when engaged in reading some absorbing book. All efforts on my own part and that of

my friends to break me of this habit have been unavailing. I am now 40 years of age, and I do not know that I have any other markedly neurotic tendency. Of course this habit in a medical man is a very bad one, as besides the disfiguring appearance there is always the danger of septic inoculation. To prevent this I often wear a finger stall. My eldest son, now aged 9 years, has bitten his nails ever since he was a baby, and when very young he used to lie in his cot with his foot in his mouth biting his toe nails. This he is now fortunately unable to do. He is in all other respects a perfectly healthy normal child. I had an aunt subject to epilepsy, a sister subject to cataleptic seizures, and an uncle is now living under my care suffering from senile dementia. I would gladly cure myself of the habit if I could, but am afraid that it would take a very great many bottles of "Another Member" before such a consummation would be attained.

F.R.C.S., who asked the question on this subject, writes that in the child of 10, whose case prompted his inquiries, he had tried in many ways to stop it, putting on gloves at a night time for weeks together, painting the finger-tips with solutions of aloes and cayenne pepper, and offering all kinds of bribes without effect. With reference to Dr. Willerforce Smith's reply, "F.R.C.S." writes: "He states, 'It is no mere habit, but belongs to a group of habitual, purposeless, fidgety movements,' etc., which means it is not a habit, but belongs to a group of habits. I know the group, but that does not alter a fact. His remedy is 'a fuller daily exercise of the unsatisfied muscular system.' My child has full meals and plenty of exercise."

NOTES, LETTERS, Etc.

Dr. ALBERT E. COPE, Public Vaccinator St. George Hanover Square (Vauxhall Bridge Road, Westminster, S.W.), writes: In view of your lead-note on "Difficulties under the Vaccination Acts," in the BRITISH MEDICAL JOURNAL of November 2nd, p. 1118, I beg to forward under separate cover a copy of the *Local Government Chronicle* of October 13th, 1895, containing an account of a meeting of the London and District Poor Law Officers' Association, at which a paper was read on the question you introduce by Mr. C. O. Elkerton, Vaccination Officer for St. George, Hanover Square. The failure of the Commission to report makes the work of the vaccination officer much more hard, but we are fortunate in this district in the possession of a Board which supports the carrying out of the law as to vaccination.

MEDICAL OFFICERS AND GUARDIANS.

The following appears in *Punch*:

Board and Residence.—Here is a gem from the Bandon Quarter Sessions: Their Medical Officer of Health, Dr. Magner, was suing the guardians of the Clonakilty Union for failing to erect a fence round the dispensary residence. Counsel argued that the true cause of all this was that Dr. Magner happened to be a gentleman of independent mind, who had not, like others in the same position, the *sa voir faire* to coddle guardians. His Honour: Do you mean to say that a very unfortunate medical officer has to coddle Boards of Guardians? A very unpleasant duty certainly. Mr. Powell: Well, they had to attend the meetings, and, perhaps, stand drinks, and things of that kind.

Who would not be such a medical officer,

Practised in keeping his Board well in hand?

Do you think that he offers them cocoa or coffee, sir?

No; but it's whisky he's called on to stand.

Paupers fall ill, and his task is to cure 'em;

In fights with infection he comes up to time;

'Cause had sanitation he's paid to secure 'em;

His drains may be poor, but his "drinks" must be prime.

Is any guardian cantankerous? He "cuddles" him

And did a counsel obscurely declare;

And should this fail, then his "Irish nob" fuddles him;

For what is a doctor without "coddle fair"?

REMUNERATION OF CIVILIAN MEDICAL PRACTITIONERS IN CHARGE OF TROOPS.

CIVIL SURGEON IN CHARGE OF TROOPS writes: I have been much interested in the answer to a correspondent appearing in the BRITISH MEDICAL JOURNAL of October 26th, which deals with the question of the remuneration of civilian practitioners who are in medical charge of troops. I remember when the Army Estimates for Medical Services were being discussed in the House of Commons a year or two ago, a gentleman named Lloyd was asked for private medical practitioners, so that the number of civilian practitioners who are in charge of troops must be a large one if I am to judge by the yearly amount I receive for discharging the duties of medical officer at a station where the average strength is about 100, and assuming that all, or a very large majority, are, like myself, paid at contract rates, for I take it, that it is only at small stations with a strength somewhat similar to that which obtains at the one I am in charge of that officers of the Army Medical Staff are retained by civilian practitioners. I hope, therefore, Sir, that you will allow some small space in the JOURNAL for an expression of opinion from one of the latter who may feel aggrieved over this very important question of "pay," and that we may rely on your powerful aid and sympathy. Until, I think, 1892, in the case of a civilian practitioner employed at contract rates, the amount was calculated on the maximum number present at the station in each month; since then the calculation is based on the average number present during each similar period, this change seriously diminishes the "sum total," more especially at a station where the troops are constantly changing for military practice. The alteration appears equitable enough, and no one could grumble at it if the contract rates of remuneration were not so ridiculously inadequate for the duties of the civilian medical officer as they now are. As he has, in addition to attending and supplying medicines to those who "come sick" and are in hospital, to attend various Boards, make sanitary inspections and reports, make countless returns—weekly, monthly, quarterly, and annual for the correctness of the contents of all of which he is responsible, the preparation of some of them being most involved and intricate, such as the annual

return of sick, which demands no small attention and time on his part)—keep a lot of books, such as the medical casebook, sanitary diary, etc. It will be thus apparent that the duties of the civilian practitioner in charge of troops are not very dissimilar, if not practically identical, with those of the regular army medical officer, while the contrast in the "pay" of both, even assuming the latter to be merely a surgeon-lieutenant, is very great indeed. In conclusion, I trust that the civilian medical practitioners in charge of troops throughout the kingdom will join together and take such steps as will ensure their receiving a nearer approach to adequate remuneration for their services than they at present enjoy.

COLEMAN AND COLEMAN.

Dr. J. FOSTER PALMER (Chelsea College, S.W.) writes: Like many other members of the profession, I have received a large number of circulars from Messrs. Coleman and Co., of Norwich, manufacturers of Wincarnia and other meat extracts, but in justice to them I am bound to say that there has never been the slightest hint or suggestion of any connection with Messrs. J. and J. Coleman, the well-known mustard makers. Neither the names nor the initials correspond, and any confusion which has arisen can only have been the result of extreme carelessness and inattention on the part of the recipient.

THE "MEDICAL DIRECTORY."

Dr. W. ALLEN STURGE (Nice) writes: In the BRITISH MEDICAL JOURNAL of September 21st you published a note from me complaining of a change introduced by the proprietors of the *Medical Directory* in their treatment of "Medical Practitioners Resident Abroad." I think it right to inform you that I have just received a courteous letter from the editors of the *Directory* in which they tell me that on further consideration the proprietors have decided to rescind the new regulation in question. As it is too late to make the necessary alterations to give effect to this decision this year, the rule now rescinded will govern the list of "Foreign Practitioners" in the forthcoming *Directory*, but in all subsequent issues the details of the list will appear under the same conditions as before.

A CORRECTION.

Dr. ILLINGWORTH (Ventnor) writes to correct the report of his remarks made upon the paper on the Functions of the Laryngeal Ventricles and Ventricular Bands, by Dr. Alexander Hodgkinson, published in the BRITISH MEDICAL JOURNAL of October 26th, page 1027. Dr. Illingworth is reported to have said that "he considered pharyngitis a mischievous doctrine." He desires to say that his observation was that it was "mischievous enough without having its effects attributed to the wrappings up of dust by mucous corpuscles."

LACERATION OF PERINEUM.

Dr. H. WILLSON (Weybridge) writes: A primipara, aged 31, was confined somewhat precipitately on July 22nd, at full term, of an undersized male child. She received no assistance till the placenta was expelled, and no medical aid was sought till July 25th, when I found an extensive irregular tear, commencing in the left labium one inch anterior to the fourchette, extending through the sphincter to the muscular coat of the rectum, and to within a line of the anus, besides reaching two inches into the vagina. On the following day, after injecting half a gr.-in of hydrochlorate of morphia into the buttock, the patient was placed in the lithotomy position, the vagina being well plugged. After cleansing, cocaine solution was freely applied, some shreds of mucous membrane removed, and the edges brought together, three deep wire and three superficial catgut sutures being employed. The bowels were relieved on the fourth day. The result was most satisfactory, only a small sinus remaining when the stitches were removed, and this has since healed. I am induced to report this case because of the length of time—four complete days—before the operation, and to confirm the fact that severe injury to the external organs may occur, though no instrumental or other aid be given.

ABSENCE OF OCCIPITAL BONES.

Dr. A. LEES SMITH (Burnley) writes: I delivered a young woman of a full-time male foetus last week. It was living up till the time of birth. It was fully developed in every way, except that there was no occipital bone. There was no skin over the space, only the membranes.

"A specimen of occipital deficiency is to be seen in the teratological collection, Museum of the Royal College of Surgeons, No. 389, but in that case hydrocephalus existed and other malformations. Our correspondent should, if possible, have his case thoroughly examined. It probably represents a very early stage of the form of monstrosity known as anencephalus.

PARSCHIPION BY POST.

OUR attention has been called by several correspondents to an advertisement which has appeared in various morning papers purporting to emanate from a "M.D." and "West End Physician," who offers to prescribe "for all ailments on receipt of full particulars of symptoms, age, etc. Fee 2s. 6d." The address to which the patients are to write is given as "M.D., care of Kelly, 2, Southampton Buildings, Holborn." A cowl does not make a monk, and the titles "M.D." and "West End Physician" do not necessarily imply that it is a duly qualified medical man who thus diagnoses himself. Should it turn out, however, on inquiry that the advertiser is a registered practitioner, the attention of the General Medical Council will be called to the case.

THE CASE OF DR. ANDERSON.

TRUTH, October 18th, says: I see that the Court of Appeal summarily disposed last Friday of Dr. Anderson's application to have his case reheard. After what has previously happened this is not surprising, but I confess I find it surprising that the judges should have said, as they are reported to have done, that "they had never heard such nonsense talked before." This "nonsense" seems to have been the contention that the Master of the Rolls was an interested party in the judgment he gave. What are the facts? That at the time of hearing Dr. Anderson's appeal Lord Esher was defendant in an action of precisely the same nature as Dr. Anderson's action against Mr. Cook, and that the judgment which Lord Esher delivered in Anderson's case was after-

wards used as authority for disposing of the action against his lordship. No one who knows his lordship would suspect him of an intention to manufacture an authority for use in his own case, but to say that his judgment may not be an unbiased one under such circumstances is only to say that he is subject to the ordinary infirmities of humanity. To his colleagues Lord Esher may appear a being of supernatural attributes, but those who assert that his lordship is only human ought not to be told that they are talking "nonsense."

PROFESSIONAL ADVERTISING.

DR. J. S. OWENS (Gorey, co. Wexford, Ireland) writes: May I be allowed to point out what seem to me to be errors in the reasoning in Dr. Potter's paper read before the Section of Ethics upon Professional Advertising, and appearing in the BRITISH MEDICAL JOURNAL of September 14th. He very correctly begins by assuming that it is absolutely necessary to answer two questions with reference to professional advertising before condemning it: (1) What it is exactly, and (2) Why it is scandalous? Having defined professional advertising, he proceeds to give four reasons why it is unethical:

1. From a public aspect. Dr. Potter seems to assume that in an advertisement to the public the medical man must promise some definite cure or result. If such were the case it certainly would be as he says "not only undesirable but fraudulent," but leaving out such promises there is still a very large field for advertising (for example, qualifications, experience, etc.) to which this objection does not apply, as it is not necessary to promise anything in an advertisement except the advantages of your particular "services," consequently the argument with reference to medicine that "just because it cannot guarantee certain and definite results it cannot like the manufacturer or the merchant honestly advertise," seems to me to be based on a fallacy.

2. In answer to the question "Where lies the precise demerit of professional advertising from a purely medical point of view?" Dr. Potter says "that it consists in this, that the professional advertiser tries to take unfair advantage of his professional brethren who do not advertise." This answer could be used equally well to support the adoption of advertising by the whole profession, for it does not show anything unethical in advertising itself.

3. "That if medical advertising were to become general, medical science would cease to advance, etc." Is not the truth of this statement assumed without sufficient proof? Would it not be just as fair to say that the greater competition which would be produced by advertising would act as a stimulus to the advance of science? Scientific advance depends much upon the efforts of those whose greatest stimulus is personal inclination.

4. With reference to his fourth reason, it seems to me that it also assumes without sufficient grounds that if advertising were to become general, it would so degrade the motives of medical men that they would consider money-getting as of first and healing of only second importance.

The root of the objection to professional advertising springs from the fact that whether rightly or wrongly it is regarded as compromising the dignity of the profession, and consequently to the orthodox medical practitioner it is forbidden ground, so that when other medical men advertise it is taking an unfair advantage of the orthodox.

THE L.S.A. LONDON.

L.S.A. writes: At an extraordinary meeting of the Royal College of Physicians of London held on October 31st, Sir William Broadbent is reported to have said that "women desired some higher status and recognition than the L.S.A., and it was a distinct disability to them not being able to get the licence of the College." It is extremely rare to find any misunderstanding now existing with regard to the status and privileges of a licentiate of the Society of Apothecaries whose diploma has been granted since June 30th, 1887, but apparently Sir W. Broadbent is under such a misapprehension. The diploma of the Society of Apothecaries dated after June 30th, 1887, is of precisely the same character, and confers precisely the same privileges, as the diploma of the Conjoint Board of the Royal Colleges of Physicians and Surgeons of London. The examinations for the diploma are of the same standard as those of the Conjoint Board, and the sufficiency of the examinations held by the Society is proved by the recent report of the visitor and inspector appointed by the General Medical Council under the provisions of the Medical Acts. Furthermore, any such licentiate is also eligible for appointments in the army, navy, and Indian medical services.

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	£0 4 0
Each additional line	0 0 6
A whole column	1 17 6
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

THE BRADSHAW LECTURE

ON

SOME NEW VASO-DILATORS.

Delivered before the Royal College of Physicians of London.

By J. B. BRADBURY, M.D., F.R.C.P.,

Downing Professor of Medicine in the University of Cambridge; Physician to Addenbrooke's Hospital.

[**AFTER** an expression of thanks for his selection for the office of Bradshaw Lecturer and a reference to the terms of the foundation, Professor Bradbury continued as follows:]

Having recently undertaken, in my capacity as Downing Professor of Medicine in the University of Cambridge, to teach and advance to the best of my ability the subjects of pharmacology and therapeutics, it occurred to me that I could not do better on the present occasion than address you on a subject in this department of medicine; and here I wish to express my obligation to my assistant, Mr. Marshall, who has rendered me invaluable aid in conducting the experiments mentioned in the lecture.

I propose, then, to ask your attention to certain vessel dilators which, so far as I am aware, have not previously been brought before the notice of the profession.

The vaso-dilating action of nitrites and nitro-glycerine has long been known, and the whole subject of their action was ably reviewed and further extended by Professor Leech in the Croonian Lectures of 1893. These compounds possess a powerful though more or less evanescent action; and as in some conditions it would be advantageous to possess a drug having a more prolonged though less powerful effect, it has been the endeavour of pharmacologists to discover such a substance. Professor Matthew Hay¹ experimented with ethyl-nitrate, nitro-cellulose, and allied bodies, but came to the conclusion that these were of no practical value. Later Dr. Leech, investigating the action of the nitrates of the fatty series, found that all these bodies possessed a dilating effect, generally of a prolonged kind.² He suggested them as remedial agents, but at the same time pointed out their liability to cause headaches. Still more recently Dr. Lander Brunton has experimented with hydroxylamine hydrochlorate, but he found this compound liable to produce gastric disturbance.³

As all the alcoholic nitrates previously examined had been found to be vaso-dilators, and as nitro-glycerine, the only multivalent nitrate used, has a powerful influence in this direction, it seemed not improbable that the drug in quest might be found among the nitrate derivatives of the higher-valent alcohols or their allies. The nitrates of erythrol, mannitol, and some of the sugars were therefore examined; later, the series was extended; but it is mainly to the results of the examination of the bodies just mentioned, and their possible bearing on therapeutics, that I ask your consideration.

Chemically, nitrates consist of an NO₃ group united to a radicle by a bond of O, thus R-O-N $\begin{smallmatrix} \diagup O \\ \diagdown O \end{smallmatrix}$. True nitro bodies, on the other hand, consist of an NO₂ group, united to a radicle by the N atom directly, that is without the intervention of an O atom—for example,

Preparation.—All the substances I have experimented with were obtained by nitrating the alcohols or corresponding compounds by means of a mixture of nitric and sulphuric acids at a low temperature. The product obtained was well washed with water and dilute alkali solution until free from acid, and was subsequently dried. The solid nitrates

¹ The Practitioner, vol. xxi, p. 11.

² BRITISH MEDICAL JOURNAL, 1893, vol. ii, p. 42.

³ Dr. Bradbury's *Handbook of Pharmacy*, 1895, p. 119.

⁴ Although I use occasionally the expression nitro compounds, all the bodies so are dealing with are in reality true nitrates. Unfortunately, the term nitro is reserved to those bodies has become so familiar from long use that it is difficult to dislodge it altogether.

were afterwards crystallised from ethylic alcohol or ether. From the alcohols the following series was prepared:

Methyl Nitrate	CH ₃ ·ONO ₂
	CH ₃ ·ONO ₂
Glycol (Ethylene) Dinitrate	CH ₂ ·ONO ₂
	CH ₂ ·ONO ₂
Glycerol Trinitrate (Nitroglycerine)	CH·ONO ₂
	CH ₂ ·ONO ₂
	CH ₂ ·ONO ₂
Erythrol Tetranitrate	(CH·ONO ₂) ₂
(Arabinol Pentanitate)	CH ₂ ·ONO ₂
	CH ₂ ·ONO ₂
Mannitol Hexanitate	(CH·ONO ₂) ₃
	CH·ONO ₂

Arabinol pentanitate, which would occupy the place intermediate between the erythrol and mannitol compounds, has not yet been prepared.

Among the sugars the nitrates of dextrose, levulose, and mannose have been investigated. Constitutionally these bodies differ from the alcoholic nitrates in containing an aldehyde or ketone group, and fewer nitrate (NO₂) groupings. Other nitrates—those of cellulose and starch—have also been examined, but as these have no bearing on therapeutics I shall not deal with them further.

The composition of the nitrates used was determined by means of a Lunge's nitrometer. This gives off all the nitrogen in these compounds as nitric oxide (NO), from which the number of NO₂ groups in the body can be determined.

Properties.—Of the nitrated alcohols the first three are liquid at the ordinary temperature of the air, the others are solid and crystalline. When pure they are colourless, and if kept in a dark and moderately cool place are stable. Exposed to sunlight and warmth they gradually decompose, turning yellow, and giving off nitrous fumes. Heated rapidly, or subjected to percussion, they explode. Methyl nitrate distils at 65° C.; but the boiling points of the glycol and glycerol nitrates have not been determined, as these bodies rapidly decompose as their boiling points are approached. Erythrol nitrate melts at 51° C., and the mannitol compound, according to Socioff, at 113° C. All these nitrates are more or less soluble in water, their solubilities showing a gradual transition from the methyl—the most soluble—to the mannitol, the least soluble. In all cases the solubility in water is slight, but in alcohol and ether they are readily soluble.

The nitrated sugars, as I have obtained them, are white or slightly yellow tenacious masses, decomposing readily, and difficult to prepare in the pure state. Like the corresponding alcoholic esters they are readily soluble in alcohol and ether, and slightly so in water.

All the nitrates when heated with alkalies give the nitrite reaction, that is, they liberate iodine from a slightly acidified solution of potassium iodide, and produce certain colour reactions (the meta-phenylene diamine test, etc.).

PHARMACOLOGICAL ACTION.

All soluble organic nitrates of the composition R·ONO₂, hitherto examined dilate blood vessels and change the normal spectrum of the blood. Their activity, however, varies within wide limits, and appears to be due to their different solubilities and liability to decomposition. The latter is, perhaps, the more potent factor,⁴ as methyl nitrate—the most soluble compound—has a comparatively slight vaso dilating effect. On the other hand, glycol dinitrate—the least stable—has a powerful action closely resembling that of nitro-glycerine. Its effect, however, is more transient. The erythrol and mannitol nitrates and the nitro-sugars, being less soluble than the other compounds, have a correspondingly weaker effect, but, as we shall see, their action is more prolonged.

The vaso-dilating action of these bodies has been determined by means of perfusion experiments on both warm- and cold-blooded animals, and the duration of this action by their effect upon the blood pressure in animals and the pulse in man. Nitro-glycerine has been largely experimented with, but as the vessel-dilating effect of this drug is now so well known I shall say little further about it.

Perfusion Experiments.—The method of perfusion through excised organs, which we owe to the genius of Ludwig, demonstrates absolutely the direct effect of drugs upon blood vessels. In such experiments there is no question of nervous action except it be a purely local one. But whether the effect of an agent be upon the terminal nerve fibrillae and innervated nervous ganglia or upon the muscular tissue of the vessel walls is of little moment. For all practical purposes it is sufficient to know that a drug acts either directly or indirectly, that is chiefly upon the peripheral vessels or upon the vasomotor centre.

For determining the action of these agents upon the vasomotor

⁴ See 2nd Hay, *loc. cit.*, p. 105.

Fig. 1.—Glycol dinitrate 0.0125 g. per kilo. body-weight in 33 per cent. alcohol, injected through catheter into stomach at 4.31 P.M. The time in this and other tracings marks seconds.

of warm-blooded animals the kidney of the sheep, as being the most readily procurable, was used. For the effect on cold blooded animals frogs and water-tortoises were employed. But in all the general effects obtained were the same, and I shall therefore confine myself to my experiments on the former.

In all the experiments, with the exception of those of methyl nitrate, a presumable strength of 1 of drug in 10,000 of blood was used.⁶ By means of ovens the excoised organ and blood were kept at the normal temperature (37° to 38° C.) and the blood was perfused under a constant pressure (70 mm. Hg.). The outflow of blood from the vein was measured at intervals of a minute, first during the passage of normal blood and subsequently during the flow of nitrated blood. Methyl nitrate in the strength of 1:10,000 has scarcely any diluting effect. In *rat*, however, it transformed a normal venous flow of 23 c.cm. a minute to one of 33 c.cm. a minute. After the perfusion of normal blood the venous outflow again reached its former level. A second and a third time vascular dilatation was produced by the nitrated blood, and each time was followed by contraction when normal blood was perfused. The other nitrates are much more powerful. Dinitrate of glycol perfused in the strength of 1:10,000 increased the outflow from 9 c.cm. a minute to 23 c.cm. a minute, and nitro-glycerine in the same strength converted a normal outflow of 9 c.cm. into one of 19 c.cm. a minute. In both cases contraction immediately followed the perfusion of normal blood, and a second and third time marked dilatation was produced by nitrated blood. Erythrol and mannitol nitrates also caused marked dilatation, the former increasing the venous outflow from 13 c.cm. to 35 c.cm. a minute, the latter from 6 c.cm. to 11 c.cm. a minute. A nitrate of dextrose containing four NO₂ groupings, and therefore corresponding to a tetranitrate, when perfused increased a normal outflow of 14 c.cm. to one of 26 c.cm. a minute. Similar results have been obtained with the other nitrated sugars.

There can, therefore, be no doubt as to the capability of these bodies to dilate blood vessels; but, as I have previously intimated, what we want to know for therapeutic purposes is the duration of their action. This is shown in the blood pressure and pulse tracings.

BLOOD-PRESSURE TRACINGS.⁷

The blood pressure tracings were mostly taken from rabbits which were kept under the influence of urethane, a drug exerting scarcely any effect upon the blood pressure.

In the case of the glycol and glycerol nitrates, an amount of drug corresponding to 0.0125 gramme per kilogramme of the body-weight was introduced. In this dose methyl nitrate had scarcely any effect, and therefore a dose of four times this amount—namely, 0.05 g. per kilo. body-weight—was used. Even in this dose, the effect was slight and transient. With the solid bodies, doses of 0.025 gramme and 0.05 gramme per kilo. body-weight were used, but, as part of the substance could be extracted from the contents of the stomach after the completion of the experiment, this does not represent the amount absorbed. In the case of the liquid bodies, the substance was dissolved, and in the case of the solid bodies, in part dissolved and in part suspended in weak ethylic

alcohol, the mixture being injected through a catheter into the stomach.

Both glycol dinitrate and glycerol trinitrate (nitro-glycerine) have a powerful action. The former (Fig. 1) in 1 minute reduced the blood pressure from 112 mm. Hg. to 42 mm., and in 4 minutes to 85 mm. The pressure then gradually rose, and 14 minutes after the administration stood at 106 mm. Hg. Later the blood pressure again fell, probably owing to further absorption of the drug, and later still commenced to rise again. Under similar circumstances nitro-glycerine produced an almost identical effect. In 1 minute the pressure was reduced from 100 mm. Hg. to 76 mm., and in 3½ minutes to 37 mm. It then commenced to rise, and 17 minutes after the administration of the drug stood at 71 mm.

Fig. 2.—Erythrol tetranitrate 0.05 g. per kilo. body-weight in 10 per cent. alcohol injected through catheter into stomach at 12.7.

The effect of erythrol and mannitol nitrates is much less evident. No abrupt fall of pressure occurs, but there is also no subsequent return to normal; 28 minutes after the introduction of erythrol nitrate (Fig. 2) a fall of pressure from 85 mm. Hg. to 63 mm. occurred, and 30 minutes later the fall was further increased to 54 mm. The subsequent fall was trifling; 2 hours 48 minutes after the administration of the drug the pressure was 46 mm. Hg., and an hour later it stood

Fig. 3.—Mannitol hexanitrate 0.025 g. per kilo. body-weight in 33 per cent. alcohol injected into stomach at 10.45.

at the same level. In the meantime the cannula had been changed from the left to the right carotid owing to a clot having formed in the former vessel. After mannitol nitrate a similar effect occurred (Fig. 3); 12 minutes after the introduction of the drug the blood pressure had fallen from 98 mm. Hg. to 84 mm. An hour later it had fallen to 60 mm. Subsequently a slight rise followed by a fall occurred; 4 hours 12 minutes after the commencement of the experiment the blood pressure still remained at 68 mm. Hg.

The effect of methyl nitrate upon the blood pressure is slight. After introducing 0.125 c.cm. of the substance (that is, about four times the quantity used in the case of the other

⁶ I say "presumable," because in a few instances, notably those of the nitrates of mannitol and the sugars, complete solution of the drug may not have occurred.

⁷ I take this opportunity of thanking Professor Schmiedeberg, of Strasbourg, for allowing my assistant the use of his laboratory for this purpose.

liquid nitrates) dissolved in 5 c.cm. of water into the stomach (Fig. 4), the blood pressure fell from 96 mm. Hg. to 70 mm.

Fig. 4.—Methyl nitrate 0.002 c.cm. per kilo. body weight, dissolved in water injected into the stomach at 11.47.30. In the course of a minute, but immediately commenced to rise again; 6 minutes 30 seconds from the commencement of

Fig. 6.—Glycol dinitrate. In the course of a minute, but immediately commenced to rise again; 6 minutes 30 seconds from the commencement of the experiment the pressure was 80 mm., and 11 minutes later was practically normal.

A consideration, therefore, of the action of these drugs upon blood pressure leads us to the conclusion that the nitrates of erythrol and mannitol have a less marked but more prolonged action than those of glycerol and glycol, and that methyl nitrate has comparatively little action. These relations are again brought out in the accompanying pulse tracings. These have been selected from a number taken under varying conditions of health and disease, and they show in a graphic manner the fall of arterial tension and its relative duration; they are, in fact, a complement to the experiments which I have already described.

PULSE TRACINGS.

The tracing of methyl nitrate (Fig. 5) shows, perhaps, a more marked fall of arterial tension than we should expect from the previous experiments, but the dose is an excessive one, being 1,000 times that of the glycol and glycerol nitrates, and 10 times that of the solid nitrates. It is, however, essential for practical therapeutics that we should know the dose sufficient to produce a salutary effect, and hence the comparatively large dose given. The arterial tension was reduced in little more than a minute, continued to fall for 16 minutes, and then gradually returned to normal. Six hours after the administration of the drug the tension was still considerably below normal—a condition not reached until the following morning.

Glycol dinitrate in 100 grain doses, like nitro-glycerine, quickly reduces tension. The tracings (Fig. 6) were taken from a young woman suffering from anemia. The normal tension of the pulse was somewhat low, but in less than a minute it was reduced still lower, and in 3 minutes was hyperdicrotic. The effect, however, was very transient, and in 16 minutes the pulse had almost reached its normal degree of tension. Fig. 7 shows the effect of a corresponding dose of nitro-glycerine. It is a little peculiar in that it exhibits a more transient effect than usual with nitro-glycerine, but otherwise it presents the same features as those obtained by other observers.

The pulse tracings of the solid nitrates show a marked difference. Thus during the time in which nitro-glycol and nitro-glycerine present their period of greatest activity these show little or no action. After the administration of 1 grain of erythrol tetranitrate (Fig. 8) no very marked effect is noticed until 50 minutes have passed; the tension then falls gradually for about 1½ hour more, and afterwards as gradually returns. In the present case 5 hours 15 minutes after the administration the pulse tension had not yet reached its previous level. In the same dose mannitol hexanitrate produces a very similar effect (Fig. 9). The pressure in the arteries is scarcely affected until nearly an hour has passed, and it has not reached its former level even after 5 hours. But the relative effects of the various members of the "nitrite group" will perhaps be better understood by reference to a diagram (Fig. 10). This has been constructed from sphygmographic tracings controlled by perfusion and blood-pressure experiments, and although it does not pretend to minute accuracy, except as regards time relations, it will nevertheless serve the purpose I have in view. The time is stated in minutes and hours, and the fall of arterial tension is represented by a fall from the base line, which in its turn is supposed to represent the normal tension. It will be seen that erythrol tetranitrate and mannitol hexanitrate are quite inactive during the period of greatest activity of the other members of this series, but that their effect is markedly prolonged.

INSENSIBILITY.

In individual cases slight differences in the extent and duration of action of these bodies are noticed, and occasionally cases are met with comparatively insusceptible to their influence. Thus, in some cases of advanced heart disease where the artery presents a feeling of fullness, but yet remains easily compressible (virtual tension of Broadbent's vaso-dilators have often little effect. In these cases the arteries, like the heart, have lost their normal tone, are considerably dilated, and, though possessing a sense of fullness and, on superficial examination, of resistance, are yet arteries of low tension. Coupling with this fact the tendency to fibrous tissue formation in the various organs in this

Fig. 7.—Glycerol trinitrate. In the course of a minute, but immediately commenced to rise again; 6 minutes 30 seconds from the commencement of the experiment the pressure was 80 mm., and 11 minutes later was practically normal.

Fig. 10.—Comparative action of certain nitrites and nitrates.

condition, we have some explanation of the comparative irresponsiveness of these cases.

In some cases of not far advanced Bright's disease in which the tension is very high, and is evidently due to causes existent in the blood, a comparatively large dose of nitro-glycerine or its allies is necessary to produce any marked reduction of tension. But apart from such pathological conditions, we now and then come across individuals who can bear large doses of these drugs with impunity. Even in animals there seems to be considerable variation of susceptibility to the action of vessel-dilating drugs, and particularly of the organic nitrates. The reason is not always clear. Habitual use tends to diminish their action, but this is obviously not the explanation in many cases. With the solid nitrates the amount of food in the alimentary canal at the time of administration, as well as its reaction, will have an important influence in determining the amount of drug dissolved, and therefore absorbed. It may be that under the influence of the alkaline juices of the intestine these nitrates are converted into nitrites (for example, sodium nitrite), but I am rather inclined to believe that this change, if it occurs at all, takes place in the blood or in the cells which form the walls of the blood vessels. Hitherto, however, I know only of one case, a man suffering from dilated heart, the result of alcoholism, in which these drugs failed to have any distinct effect.

The action of organic nitrates upon other organs is of little practical importance. Upon the heart the direct effect of these compounds is very slight. Indirectly, owing to the diminished work consequent on dilatation of the blood vessels, increased rapidly and sometimes palpitation (especially after glycol and glycerol nitrates) are noticed. Certain nervous effects have been attributed to nitro-glycerine, but none have, as yet, followed the administration of the solid organic nitrates. The effect upon the urinary excretion is practically nil. These bodies, as far as they have been investigated, are not diuretic.

As ordinarily administered the organic nitrates possess no cumulative action. The continued use of nitro-glycerine produces a lessened susceptibility to its effects, but this has not yet been noticed after the administration of the erythrol and mannitol compounds.

Reviewing the action of these compounds upon the vascular system in regard to their practical application to the treatment of disease, I think we may, at the present at least, discard methyl nitrate as being the least likely to prove of clinical value. Glycol dintrate again is so similar in action to nitro-glycerine and, at the same time, so much more expensive, that it also is not likely to enter into our stock of remedies. The longer acting nitrates, however, may prove of value.

THERAPEUTIC INDICATIONS.

From the pharmacological action of these two nitrates, it would seem that the chief indication for their use is a condition in which the heart is labouring under increased work imposed upon it by contracted arteries. As life advances the hitherto elastic vessels become converted into more or less rigid tubes, the fibrous adventitia is thickened, and fibrous tissue replaces, to a greater or less extent, the muscular and elastic tissue of the middle coat. As a result, increased work is put upon the heart, and hypertrophy results. Sooner or later, however, central or peripheral degeneration occurs: either the heart fails from the increased strain put upon it on the one hand, or causes rupture of a vessel from excessive power on the other. In disease the normal evolution may be compressed into a much shorter space of time; thickened arteries and hypertrophied hearts may be found comparatively early in life; and the final results may be the same. If by any means we can dilate the vessels we diminish the work of the heart and the pressure upon each unit of area of the artery, and thus in both ways avert the tendency to death. Our difficulty hitherto has been, not so much to reduce arterial tension when desired as to keep the tension steadily below a certain level. Both nitro-glycerine and sodium nitrite have been used for this purpose, but their administration is attended with some inconvenience. As we have seen (Fig. 10) these drugs have comparatively little action after two hours, and it would therefore be necessary to give them at least every two hours to produce continuous low tension.

Even then there would be considerable variation in the arterial pressure. By the substances I have described the tension is not brought so low but the reduction is of longer duration and the pressure is less liable to fluctuation. They are also, as far as I am aware, free from poisonous properties, a quality readily explained by their slight solubility.

CARDIAC PAIN.

Under this name I include all forms of pain accompanying diseases of the heart or vessels. I adopt it in preference to angina pectoris, as the limits of this disease appear to vary with different authors; and while some would almost confine it to Heberden's classic form, others would extend it to cover the whole realm of cardiac pain. In cardiac pain always accompanied by contraction of the arterial walls, and if so, is it the relation one of cause and effect? Since Dr. Lauder Brunton's discovery, the question has been asked many times, but there has been no unanimous answer. Some observers state that obvious increase of tension does not always accompany heart pain, and I agree with them; but, as Dr. Leech pointed out, the increase may be more relative than absolute. In a heart weakened by disease, a very slight increase of resistance may prove too much for the heart to overcome. This slight increase may be due to a general effect almost inappreciable in any one artery, or to an effect localised in one or more areas. Of greater significance is the fact that vaso dilators do not always relieve angina-like pains, especially if these occur in cases of far advanced heart disease with a low tension pulse. In such cases morphine is of much greater value.

Can attacks of anginal pain be prevented by keeping arterial pressure below its normal level? Obviously this is the only way in which the solid organic nitrates can be of service. When an attack has come on, it is necessary to resort to more quickly acting drugs, and in cases of a sudden and severe nature inhalation of the fatty nitrites is advisable. For cases in which the pain is less severe and of longer duration the administration of nitro-glycerine or sodium nitrite is perhaps more beneficial. But if we can prevent the advent of these attacks, a great stride ahead will have been made. Much may be done by the exhibition of purgatives and attention to the general health, but in the majority of instances something more is needed. This something is I believe a vaso-dilator. Hitherto nitro-glycerine and sodium nitrite have been the drugs mainly used; but their evanescent and varying action render them unsuitable. Nevertheless, I have seen cases in which the continuous administration both of nitro-glycerine and sodium nitrite seemed to prevent the occurrence of anginal attacks, and other physicians have reported similar results. In many of these cases, however, attacks occasionally developed, and it is quite possible that longer acting remedies, such as erythrol nitrate, might have prevented them altogether.

CHRONIC BRIGHT'S DISEASE.

The most important change, and the one which affects us most closely, is the arterial thickening attending Bright's disease. This leads to hypertrophy of the heart, and both combined to a high tension pulse. Sooner or later, if the patient does not succumb to uræmia or some intercurrent disease, the increased vascular strain begins to tell either upon the heart or on the vessels, often on both. Either the symptoms of heart failure develop or attacks of apoplexy occur. Previous to such terminations headache, mental inaptitude, weariness, and similar symptoms are not uncommon, and sometimes these may be noticed, with a high tension pulse, where no other direct evidence of renal disease exists. In all such cases the longer acting vaso-dilators are often beneficial. I do not wish to convey the impression that I regard the thickened condition of the arteries as the primary cause of the high tension of Bright's disease. This, I believe, is due in the first instance to an impure condition of the blood, and the correct treatment under the circumstances is to rid the blood as far as possible of this impurity. Once, however, the fibroid and muscular thickening in the arteries is produced it becomes a danger in itself. It is a condition we cannot cure, and our treatment must therefore be symptomatic. By keeping down the arterial pressure in such conditions we may not only alleviate unpleasant symptoms, but

may also prevent the onset of such disastrous conditions as cerebral hæmorrhage. The fibroid thickening of the blood vessels does not annul the action of these nitrates, though it diminishes to some extent their power.

I do not anticipate any beneficial action from these drugs upon the kidney disease itself. They are not diuretic, at the same time they are not irritant to the kidney, and, given even in acute inflammatory conditions of these organs, are not likely to produce ill effects.

ANEURYSM.

In cases of aneurysm (I confine my remarks at present to those coming under the care of the physician) it is very necessary to keep the circulatory system as far as possible in a state of physiological rest. This is best accomplished by dilating the peripheral arteries, and for this purpose potassium iodide has for some time been the drug most in vogue. Without detracting in the least from the value of potassium iodide in this condition, it seems to me that the nitrates of erythrol or mannitol will accomplish this end better, and will give more satisfactory results in cases not of syphilitic origin. The pain which accompanies aneurysm is not often relieved by vaso-dilators, and, therefore, I do not anticipate any benefit from the drugs I have described. Usually the pain is a pressure effect which is only relieved by the administration of morphine.

RAYNAUD'S DISEASE.

Of other conditions connected with the contraction of blood vessels Raynaud's disease is one that has been successfully treated with nitro-glycerine. If vaso-dilators are of value in this condition, it seems to me that erythrol nitrate, as tending to keep up a more constant dilatation, would be of greater value.

DYSPNOEA.

With regard to respiratory conditions, I do not anticipate any beneficial effects from these bodies. In various forms of dyspnoea—uræmic, asthmatic, bronchitic—nitro-glycerine and the nitrates are sometimes of value, but they often fail to relieve. By their means sibilant rhonchi may be converted into sonorous, and sometimes may even disappear altogether, but I do not agree with Professor Fraser¹ as to the rapidity of this change. The change of pitch seems to occur *pari passu* with the fall of arterial tension, and in the majority of cases the effect is not marked. Where loud and numerous moist sounds are present even less effect is obtained. Seeing, then, that the action of these comparatively powerful vaso-dilators is not very distinct, we should not expect the less powerful drugs I have mentioned to exercise much influence. They may prove of prophylactic value in the dyspnoea occurring in Bright's disease, for example, but beyond that it would be useless to hazard conjectures. In chronic bronchitis and other conditions in which the dyspnoea is of cardiac origin, amelioration might be obtained from these compounds. In such cases the weak heart is unable to drive the blood with sufficient power along the arteries, stagnation therefore occurs in the veins, and the pulmonary system is often the first to suffer. Thus aëration is limited by the pulmonary lesions on the one hand and the cardiac on the other. By dilating the vessels, and thus relieving the heart, the circulation becomes more efficient and the blood is better aërated. But under such conditions, digitalis is usually of much greater benefit. Headache occurring in a case of chronic bronchitis, with full, rather tense pulse, disappeared after the administration of erythrol nitrate.

HEADACHE.

It is also very probable that anæmic headaches, occurring in patients with a high tension pulse, may be relieved by this drug, but my observations on this condition have been confined to those with a low tension pulse, and here the results have been somewhat conflicting.

NERVOUS DISEASES.

Although nitro-glycerine has been given in many nervous affections, I do not think much benefit will follow the use of erythrol or mannitol nitrates in these diseases. Migraine and neuralgia are oftentimes accompanied by reflex con-

traction of the blood vessels, and the use of vaso-dilators has sometimes proved curative. The solid organic nitrates, however, are much too slow in action to be of benefit, though it is possible they may prevent attacks of migraine if administered continuously.

The drugs might also be used by those who believe in the value of nitro-glycerine in epilepsy, but as I have rarely used this drug in this affection my experience on this point is limited. Other nervous diseases—epileptic vertigo, cerebral congestion, and tetanus—in which nitro-glycerine has been used, are not likely to yield to treatment with the nitrates under discussion.

In many other conditions nitro-glycerine is said to have proved of value. In various forms of poisoning (opium, coal gas, etc.), in vomiting from any cause (pregnancy, sea-sickness), in lenteric diarrhoea, in diabetes mellitus, in hysterical paralyses, and many other affections, nitro-glycerine is said to have proved curative or ameliorative. This is difficult to understand, and in most cases the results obtained were probably coincidences. I do not think that other organic nitrates will give beneficial results when administered in these or similar affections, and therefore I do not advise the use of the nitrates under consideration in such conditions.

DOSE AND ADMINISTRATION.

The dose of the solid organic nitrates may be taken as 1 grain; more may be given if it is thought necessary, but usually this amount will suffice. They may be taken in the form of pills or tablets, or in alcoholic solution. The last method I prefer. A solution of erythrol nitrate in the strength of 1 in 60 may be made and 1 drachm may be taken in an ounce of water every four or six hours. Mannitol nitrate is not quite so soluble, but a 1 per cent. alcoholic solution can be prepared, of which 1½ to 2 drachms may be taken in water. The solutions thus made are stable and free from irritating properties.

CONCLUSION.

In conclusion, the only condition in which I think these nitrates will be of benefit is one that I have already alluded to, namely, high arterial tension. Whenever we wish to keep down the blood pressure for a length of time, then I believe these nitrates will be of value. Such a result may be necessary for many reasons; a few I have attempted to indicate. It may be that the therapeutics of the drugs will widen with our increasing knowledge; it may be that the limits I have laid out for them will be much diminished; but whichever it be, I thought that a lecture devoted to the pharmacological action and therapeutic indications of a drug of which we stand so much in need would not be alien to the noble purpose which the foundress of this lecture had in view.

Although I know of no evil effects having followed the administration of these drugs, and though no such effects are anticipated, I ought to say that the research on these compounds is not yet complete.

CARBOLIC ACID POISONING.—In the course of an address to the Sheffield Chemists' Association last week, the President of the Pharmaceutical Society is reported to have said that the Council intends to make a renewed attempt to have carbolic acid placed on the poison schedule of the Pharmacy Act, together with a number of other articles. This is satisfactory intelligence, and so far as carbolic acid is concerned the daily occurrence of deaths caused by it either accidentally or in cases of suicide affords strong evidence of need for protective regulation of its sale. It seems unaccountable that a poison which occupies such a conspicuous position in the returns of the Registrar-General should have been allowed so long to be supplied indiscriminately in all kinds of shops to children as well as adults, and without any provision against accident. The fact that carbolic acid is useful as a disinfectant for sanitary purposes cannot be urged as a justification of this laxity, since there are various forms in which it would be equally serviceable for such purposes, and at the same time unlikely to be swallowed in the way that so frequently happens with carbolic acid in its natural condition.

¹ International Journal of the Medical Sciences, vol. xov, p. 122.

AN ADDRESS

DELIVERED AT THE OPENING OF

THE SECTION OF OTOTOLOGY,

*At the Annual Meeting of the British Medical Association, in London, July-August, 1895.*By SIR WILLIAM DALBY, M.B., F.R.C.S.ENG.,
Consulting Aural Surgeon to St. George's Hospital.

BEFORE we commence the work of this Section, I permit myself to say a few words of introduction: but in conformity with the wishes of the Council, which anticipate my own views of the matter, I refrain from occupying your time by anything in the nature of an address.

In consequence of the meeting of the International Otolological Congress at Florence we shall not have the assistance of many Continental visitors who otherwise would have come to this meeting; but, on the other hand, Scotland, Ireland, and the provinces will, I believe, be represented more completely than is usual at our annual gatherings.

The programme is before us, and besides papers of considerable interest we shall have the privilege of hearing from Professor Macewen, whose brilliant achievements in cranial surgery are so familiar to us, his views on the grave questions involved in operative measures which become necessary when the process of inflammation has proceeded from the middle ear to the cavity of the cranium.

As to other matters before us, I am conscious—as everyone must be who sincerely wishes to advance our speciality—that, dealing as we do with so small an area of the body, it is difficult to be quite certain of very much progress after every annual meeting. Still, if we conduct our deliberations in the truly scientific spirit, I feel sure that each one of us has in his practice observed some points which have escaped the notice of others. It is in this way that we have individually at various times been able to give and receive something which has been of permanent value to those who follow our art, and I hope that this meeting may be an occasion for much interchange of ideas and experiences.

In regard to the treatment of the various forms of "nerve deafness," I wish to say that the words in which this discussion have been described were not chosen without due deliberation. The term "nervous deafness" is intended to include not only disease of the nervous apparatus, but loss of hearing due, as we know it to be, to causes which affect the whole nervous system generally; also loss of hearing due to shock or to emotional and mental influences; lastly, those conditions which, beginning as they do within the tympanic cavity, and at first simply interfering with the conduction of sound, finally are found to involve the perceptive as well as the conducting media, and to be the starting point apparently of subjective nervous phenomena. In short, the title of the discussion has been made purposely vague in order that when the subject of treatment is discussed it should be incumbent on the speaker to be exceedingly definite as to the precise nature of the cases for which the treatment is proposed; for in debating or writing upon so difficult a question, nothing is so obstructive to real progress as dealing with generalities. What we desire is thoroughly to thresh out the subject, so that we arrive at the approximate value of various methods of treatment which seem to require a more complete accuracy as to the conditions which they are supposed to combat. We know that we are often unable to point to a definite organic change within the nervous apparatus, but at least we wish to be able to point to the *modus operandi* of the remedy upon the function of the special sense. This anxiety for a more firm basis on which to place various remedies applies especially to the use of pilocarpin and electricity.

At one time great hopes were entertained in the profession as to the value of pilocarpin, and yet when the subject was discussed at a recent meeting of this Association at Newcastle it found very little support, even from those who had given it a fair trial. Again, it cannot fail to have been observed how in many nervous disorders great temporary benefit has

followed the use of electricity, but the permanent effects have very frequently not been maintained.

We hope at this meeting to hear something definite as to the real value of both these agents, and to receive some helpful suggestions as to the conditions, if any, where they may be expected to prove useful.

It is noteworthy that in our list of papers we have none upon a subject that must incessantly agitate the minds of aural surgeons. I refer to the operative proceedings upon the tympanic membrane and cavity of the tympanum for the relief of chronic change; for notwithstanding all the disappointments in this direction, the fact remains that some of us (and I include myself in this number), after years of careful observation, are still in a position to make a selection of cases in which we are reasonably confident that if we could make a permanent and large opening in the tympanic membrane the hearing would be restored to a most useful extent. It is, I believe, in this complete knowledge that the impulse is to be found for all the operations that have from time to time been proposed. It is to an incomplete knowledge in the selection of cases that the great proportion of failures have occurred. Impressed as I am with the brilliant future of surgery in all its departments I cannot but believe that some day or other (it may be at a distant date) one of us is destined to solve this much-debated problem.

A CASE OF PULSATORY TINNITUS.

By Sir WILLIAM DALBY, M.B., F.R.C.S.,

President of the Section.

THE PRESIDENT showed a patient, a young lady aged 15, with whom a loud grating sound in the left tympanic cavity could be heard by the bystanders. The sound was something like the loud tick of a watch, and was synchronous with the pulse for several beats; it then stopped for a brief interval, and was then resumed. This remarkable symptom came on suddenly in February, 1894, and had remained ever since. At that time, as now, she was in excellent health, and the symptom is neither more nor less pronounced than it was seventeen months ago. The beats can be observed to vary in number. Thus it was noticed to beat 7 times—an interval, then twice—an interval, then 4 times—an interval, then 13 times. The hearing is not affected. No position or movement of the body, or indeed any condition that has up to now been noticed, appear to modify it. Both tympanic membranes are normal. Sir William Dalby had only met with two other cases of a similar nature.

A DISCUSSION ON THE TREATMENT OF NERVE DEAFNESS.¹

I.—DUNDAS GRANT, M.D., F.R.C.S.,

Surgeon to the Central London Throat and Ear Hospital.

THE indefiniteness and discordance of the reports as to the methods and results of treatment of so-called "nerve deafness" are eminently embarrassing to the earnest practitioner of aural therapeutics, whether he be a tiro in the art or an experienced professor. In the first place, the looseness of that very convenient and possibly indispensable term, "nerve deafness," is the source of endless discrepancies. I feel sure that nothing like certainty in treatment can be attained without greater accuracy in the diagnosis of the different forms of disease to which the term is applied; but, as time will not permit of my dealing with the subject of diagnosis, I will pass on to the means of treatment at our disposal, which are many in number but of specially local character. They include the application of cold by means of icebags or Leiter's coils; the application of heat—of some value as a local sedative, but in general to be avoided as tending to lower the vasomotor tone; local depletion, by means of living or artificial leeches on the mastoid vein or of free puncture of the turbinated bodies; general depletion—by venesection in the arm or the neck—effects less directly the same purpose when general plethora calls for it.

Derivation Directed towards the Intestines, the Kidneys, the Skin, or the Nose.—Derivation to the intestines is an old and valuable method of treatment in all cerebral congestions or inflammations. When the labyrinth is the seat of invasion,

¹ Communicated to the Section of Otolaryngology, 1895.

traditional as well as modern scientific therapeutics would indicate the free administration of purgative doses of calomel. The skin as a means of derivation may of course be set in action by heat or sudorifics. I have elicited from several patients affected with chronic internal ear disease of syphilitic origin that they always heard better after profuse perspiration, whether induced by a Turkish bath or by active exercise. We now possess, however, a remedy—pilocarpin—which combines with this action that of a stimulant to the absorbent system. There is considerable evidence of its efficacy in aiding the removal of pleural and peritoneal effusions; and when the effusion takes place in the perilymphatic or endolymphatic spaces of the labyrinth, it appears to have even a special value if only it is employed at a stage when the effusion is still susceptible of absorption—that is to say, before it has become organized so as to mat together the delicate structures in the organ. It must also be premised that the primary action of the lesion—effusion or hæmorrhage—has not been so tempestuous as physically to damage the nerve terminations irretrievably. In all cases, therefore, of recent effusion into the labyrinth, whether hæmorrhagic, serous, or purulent, it is our absolute duty to avail ourselves of this valuable remedy, whatever other means we may use in addition. In old-standing cases it should only be used, if at all, with the greatest caution, as the probability of any benefit being obtained is of the slightest, and the risk of injury from the remedy is not inconsiderable. The patient should be made well aware of these conditions before the treatment is undertaken. In cases of intermediate duration there is every justification for its use.

In anæmia of the labyrinth it is absolutely contraindicated; in congestion it is advisable, in hæmorrhage indispensable. In acquired syphilis it is, within a year of the primary inoculation, to be employed in mild form along with mercurial treatment, with every certainty of recovery being brought about; but in advanced tertiary cases, although the prognosis—especially if the deafness has been of considerable duration—is most hopeless, the remedy should be used alone and thoroughly before the institution of any other anti-syphilitic treatment. If within a fortnight no remedial effect is produced, the drug should be laid aside as not likely to be of further use, and in its place we should resort to iodide of potassium in doses as large as 30 grains thrice daily, with or without inunction of mercurial ointment. Hereditary syphilis of the labyrinth is notoriously rebellious to all treatment, but Professor Gradenigo has published a case, Dr. Wm. Hill has mentioned to me another, and Professor McBride has reported one at least in his practice in which the pilocarpin treatment has produced beneficial results. I have myself seen considerable improvement in a well marked case, but my experience affords me no hope in old-standing cases of obtaining what may be termed a cure.

Those cases in which labyrinthitis arises from mumps call unmistakably for pilocarpin. In leukæmic labyrinthitis its use is justifiable but secondary; in infectious cases it is called for as soon as restoration of strength justifies its use. The comparison of two cases published in the *Archives of Otolaryngology*, vol. xiv, p. 138, emphasises the value of the drug in such affections. Rheumatic labyrinthitis from exposure to cold is certainly an indication for its employment. In traumatic effusion the uncertainty of the diagnosis renders the use of the remedy questionable, where concussion may be present and be followed by recovery, which in case of destructive hæmorrhage, neither pilocarpin nor anything else could bring about.

Labyrinthine disturbance due to sudden loud noise calls for its use early, along with inflation and suction, especially if there is concomitant definite vertigo, but in gradual labyrinthine deafness, due to prolonged exposure to noise, as in boiler-makers, it should be avoided.

Toxic deafness calls for other treatment. In senile deafness it is contra-indicated, and new growths, it need hardly be said, are not affected by it.

Derivation to the nose has been already referred to, and whether as a highly sensitive area suitable for the practice of counter irritation or a vascular one connected more or less directly with the ears and highly convenient for depletion it may be submitted to galvanic cauterisation or to puncture of the inferior turbinal.

Rest, both functional and physical, is a factor too little called into requisition. In labyrinthine hæmorrhage attended by vertigo rest of the body is to be strongly insisted on, with a view to the avoidance of the attacks. In pernicious anæmia, and particularly leukæmia, it should be absolutely enforced, with the aim of avoiding further effusions. Functional rest is all important in cases of nerve deafness due to prolonged exposure to noises.

The use of local antiseptics in the ear is particularly indicated in suppurative inflammation of the middle ear and in infectious disease—scarlatina and diphtheria—affecting the naso-pharynx; they should be used in the nose as well. The general antiseptic most indicated in such cases is the biniodide of mercury, there being good reason for avoiding quinine and salicylic compounds.

Sedatives are of great value in the stage of extreme mental disturbance induced by sudden labyrinthine effusion, and also in that of the mental depression sometimes reflexly induced in the subjects of deafness, whether of tympanic or labyrinthine origin. Among local sedatives may be ranked the galvanic current, the positive pole being applied by means of a small pad to the tragus, the negative by means of a large one to the back of the neck. The strength of current may be gradually increased to 4 or 5 milliamperes per ear, and great care should be taken to avoid sudden interruptions. This treatment, as a sedative, is only of use in tinnitus accompanying slight nerve deafness.

With a view to promoting the absorption of plastic effusions recourse has long been had in therapeutics to such remedies as mercury and iodine or iodide of potassium. In the early stages of syphilitic infiltration, when it is presumably more liquid and therefore more readily absorbed, we should supplement, and possibly for the time supplant, these by the use of pilocarpin.

I may in this place mention the mode of dosage which I am accustomed to employ. A solution of the strength of 1 in 24 is prepared, and on the first occasion (if an adult) 2 minims— $\frac{1}{4}$ grain— $\frac{1}{2}$ centigramme, is injected. Each time an addition is made of $\frac{1}{2}$ grain, till as much as $\frac{3}{4}$ grain, or up to $\frac{1}{2}$ or $\frac{3}{4}$ has been administered, according to the patient's tolerance. Before this it is often necessary to stop the increase, or even diminish the actual dose for a day or two. The treatment should be carried on for at least a fortnight, or, if intermissions have been necessary, for three or four weeks.

Local stimulation in the form of electricity may be applied by means of the continuous current, the negative pole being placed on the tragus, the positive on the back of the neck. The strength of current may range from 3 or 4 up to about 10 milliamperes. In well-chosen cases I have certainly seen good effected, and most particularly in uncomplicated labyrinthine disease caused by continuous exposure to noises, as in two railway engine drivers treated for me in the electrical department of St. Bartholomew's Hospital by Dr. Lewis Jones. Strychnine in fairly large doses is beneficial in cases of nerve deafness arising from general debility and anæmia.

Tonics are very often called for, and strychnine is one of the best, the indications for it being very simple. There is, however, another—quinine—of which the same cannot be said. We know how the drug will produce in the normal ear deafness, with diminished bone as well as air conduction, and at the same time tinnitus, often pulsating, and diminished by compression of the vertebral arteries. This would seem to indicate an arterial congestion of the labyrinth, and in cases of anæmia of the part the law of *contraria contrariis* would indicate the employment of the remedy. Unfortunately the *modus* of the physiological operation of the remedy is still a matter of controversy.

In genuine Ménière's disease, in which, from the absence of the functional indications of middle-ear disease and the presence of nerve deafness with typical Ménière's complexus, we are justified in diagnosing effusion into the labyrinth, our resources at the commencement are bromide of potassium, and, above all, pilocarpin. At a later stage an endeavour should be made by the use of mercury and iodide of potassium to induce absorption of the exudation. If, on the other hand, the vertigo renders the patient so miserable or useless, as it often does, as to make the loss of hearing (especially if unilateral) a matter of secondary importance, then, without the slightest doubt, quinine is called for.

In a very striking case referred to me at the West End Hospital for Nervous Diseases, the patient declared himself a "new man" within a week after the starting on quinine in doses of two grains three times a day along with 20 minims of dilute hydrobromic acid.

In yet another class of cases quinine proves of considerable service, acting in these in a somewhat paradoxical manner, and in small doses toning up the nervous system with beneficial effect in cases where fatigue of the auditory nerve from overwork and mental strain gives rise to impairment of hearing and nervous tinnitus.

Depressants are called for in certain cases, such as those of sudden labyrinthine lesions in gouty subjects, and in these the specially-indicated drug is colchicum.

Suggestion is a means of some importance as an adjuvant in the treatment of hysterical deafness, because, although many of the subjects of hysteria are not readily hypnotised, the majority of them are so, and on this is founded the "auto-suggestion" theory of the disease. This means, very shortly, that the patient who is susceptible to suggestion may hypnotise herself into a condition of deafness, which must be carefully distinguished from simulated deafness. The endeavour to hypnotise her out of it should be made when the classical treatment by means of valerian, tonics, electricity, good diet and regimen, and rectification of uterine disorders leave us in the lurch. In the hysterical deafness occurring in young girls in whom the advent of the menses is delayed spontaneous recovery may be looked for on the establishment of the catamenia.

Professor Urbantschitsch has, from the brilliant results obtained by acoustic exercises in his devoted labours among deaf mutes, been led to apply these to cases of nerve deafness.

In even the very worst cases our resources are not exhausted before we submit the patient to a course of training in so-called "lip reading," the rapidity with which an intelligent person with reasonable good sight under skilled tuition becomes an adept in the art being most remarkable.

I would submit the following points for consideration:

1. The necessity of careful diagnosis of the different conditions giving rise to so-called nerve deafness.
2. The great value of treatment by means of pilocarpin in fresh exudations into the labyrinth; its comparative uselessness in old-standing changes in the labyrinth; its action when at the moment beneficial being usually only transitory.
3. The recognition of the functional character of many cases of nerve deafness.
4. The recognition of the changes in the auditory faculty produced by senility, and the avoidance of errors in prognosis and of too energetic treatment.
5. The recognition of the frequency of middle-ear disease as a cause of Ménière's symptoms.
6. The hopeful use of galvanism in functional nerve deafness, and even in pure nerve deafness produced by habitual exposure to noises in subjects who are not highly nervous.

I trust that these fragmentary introductory remarks will elicit reports as to both failures and successes on the part of those who have employed the measures I have spoken of.

II.—H. MACNAGHTON JONES, M.D.

THE more we know of the physiology of hearing and of the relative parts played in the transmission of sound waves by the tympanic membrane, ossicles, perilymph, and endolymph to the epithelial elements, utricular, saccular, and cochlear, and of our difficulty in understanding the method by which such epithelial elements convert these sound vibrations into complex sound nerve impulses, the greater difficulty we have in isolating clinically those defects in hearing to which we are inclined to apply the term "nerve deafness." Disease in certain portions of the vibratile media, as, for example, the base of the stapes, the osseous and membranous labyrinths, involving not alone their fluid contents, but possibly also the integrity of the essential functional epithelial elements of the labyrinth, brings about results which it is impossible with any claim to accuracy to differentiate from alterations of the auditory nerve itself. Indeed, intratympanic changes, when associated with varying degrees of labyrinthine mischief, are in themselves most difficult to isolate apart from those of the auditory nerve. Our ignorance still of the relative parts played by the vestibular and cochlear branches

of the auditory nerve in the sense of hearing, as also of the exact function, relatively and proportionately, discharged by the various epithelial elements in the macula, crista, and basilar membrane, with Corti's organ, and their connective nerve fibrillae, renders the term "nerve deafness" a highly presumptive one. In fact, I hope I shall not be considered an otological sceptic unworthy of attention if I say that I regard it from the clinical point of view as in a great many cases the outcome of a purely empirical differential diagnosis. In saying this I am aware that I lay myself open to the rejoinder that my attitude in presenting the cases I am about to do to the Section is a paradoxical one, and I should myself hypercritically be inclined to take exception to their strict inclusion under this heading to the entire exclusion of associated extranervine pathological changes. The otologist, in this respect, has a disadvantage as compared with the ophthalmologist in the absence of that direct observation of objective nerve changes which the ophthalmoscope directly reveals when the dioptric media are healthy.

Here is an example of the class of case I refer to: A lady, aged 44, is subject to a great shock and fright. Her hearing up to this was, so far as she knew, normal; after this shock she finds a noise in the left ear, and there is deafness. She has attacks of migraine, with a sensation as if some "hot water was rushing up the back." On examination a few years subsequently the hearing of the right ear is found but little influenced. In the left the watch was not heard on contact; the acoumeter is barely heard. The tuning fork is not heard off the ear, and hardly heard in the left ear through the cranial bones, and closure of the meatus makes no difference. There are naso-pharyngeal complications, and the left nostril is much obstructed. She hardly inflates the left tympanic cavity, and there is rigidity of the membrane. The tinnitus is distressing, but the attacks of migraine have ceased.

I have made a selection of 50 cases of extreme deafness, in which I consider there can be no doubt that the auditory nerve was affected in some part of its course. The principal tests of hearing applied to all cases were the ordinary watch and chronometer, the acoumeter, and the tuning fork. Only those are recorded in which the hearing was reduced to (a) neither watch nor acoumeter being heard on contact, or the tuning fork being either not heard or badly heard on the head, the sound dying entirely away on closure of the meatus; or (b) where the watch and acoumeter were barely heard on contact, the tuning fork being very badly heard, the sound diminishing on closure of the meatus; or (c) lesser degrees of deafness, as measured with watch, acoumeter, and tuning fork, but in which the hearing was still greatly decreased in response to the same tests. In a number of the cases such collateral evidences of nerve involvement as migraine, tinnitus, and pain in the head, were present.

The following is an analysis of these cases, showing the causes to which were ascribed the occurrence of the deafness, and those which could be traced upon examination:

Of the 50 cases, 31 were females and 19 males; 5 were under 20 years of age, 8 between the years of 20 and 30, 14 between 30 and 40, 9 between 40 and 50, 8 between 50 and 60, 3 between 60 and 70, and 3 over 70. I have excluded every case in which there were marked evidences in the appearances of the membrane, or of gross changes in the tympanic cavity. Where such evidences were even in a slight degree present, I have noted the case as one of middle-ear involvement. In 33 of the cases both ears were affected; in 15, one. Tinnitus of varying degrees of intensity and complexity were present in 41 of the cases. The middle ear was involved to the degree mentioned in 20. There were nasal complications such as deviation of the septum and chronic hypertrophic rhinitis present in 15.

The causes ascribed and detected were as follows:

Heredity	...	6	Prolonged cursing	...	1
Deafness in family	...	9	Scarlatina disease	...	1
Tropical climates	...	3	Concussion	...	1
Frugancy	...	3	Blowing on head	...	2
Menopause, due to the	...	1	Adenoiditis	...	1
Menses	...	2	Atrophic rhinitis	...	1
Scarlet fever	...	2	Pain auto-ocula	...	1
Croup	...	2	Losses in childhood (nature)	...	1
Measles	...	2	Loss of hearing	...	1
Diphtheria	...	1	General attack of uncertain	...	1
Syphilis	...	2	Onset occurring suddenly at	...	1
Associated with mental	...	2	Right	...	1
phases	...	2	Fracture of the base of the	...	1
Mental overstrain	...	4	skull	...	1

Looking more closely into these causes, and grouping them according to their affinities, we find that in the 50 cases:

In 15 there was either distinct evidence, at one or both sides of the parentage, of hereditary deafness, or of other members of the family having suffered.

In 6 deafness was ascribed to illnesses associated with residence in the tropics.

In 5 there was a history of acquired syphilis, 2 of these cases being due to infection through conception; in 1 there was also the evidence of hereditary syphilis in the family; in 2 there was the history of severe syphilitic infection, and syphilitic reminders were present.

In 4 there was a history of measles or scarlet fever in early life, and the origin of the deafness was ascribed to these exanthems, though the ear was not affected at the time of the illness.

In 4 there was an association between the origin of the deafness and great mental strain, and in these there were present other mental symptoms, such as melancholia, depression, hallucinations of sound, insomnia, etc.

In 3 pregnancy and labour were given as the source of the deafness.

In 2 the deafness began after an attack of mumps.

In 2 there were distinct manifestations of gout.

Diabetes and albuminuria were associated with 2. The accident of a fall into the sea was the origin of 1 case, and in 2 a note was taken of the patient having been in the habit of diving on the head from heights. In only 1 case was cardiac disease detected. In the case of adenoids both parents were deaf. The concussion case was that of a man who had worked for years in a foundry and near the hammer, one ear only being affected.

I would draw attention to the following facts in regard to the etiology of these cases:

1. The proportion of females affected being 31 to 19 males.
2. The hereditary or congenital nature of a large number of these cases.
3. The causes ascribed for the deafness in several of these latter cases being such as pregnancy, residence in tropical climates, or a nasal affection.
4. The number complicated with nasal deformity or disease.
5. The large number in which the hearing of one ear remained unaffected, or in which the hearing was fairly good. Save in a few instances, where the corresponding nostril was completely obstructed, there was no special reason for this immunity.
6. Residence in India, and mental over-strain, as causes of nerve deafness.

I have chosen this 50 as the last on the list of similar patients who are constantly consulting all of us, as fairly typical ones. Do we learn any practical lesson from their histories and examinations as regards treatment? I do not enter into the treatment of each of these particular cases. If I may give a general opinion of the result in these and similar sufferers who submitted to any treatment, when told candidly that the result was quite uncertain and at best but problematical, I should describe it by the one word "unsatisfactory." In most of the cases the deafness had lasted a considerable time before I saw them. In those in which there was evidence of middle-ear implication, treatment by throat gymnastics, rectification of the nasal obstruction, Eustachian catheterisation, faradisation of the tubal muscles, massage of the mastoid, and general attention to the middle-ear ventilation, did some good, and in some instances decidedly repaid the patient for the time, annoyance, and little money expended upon it. This treatment was combined with the bromides, hydrobromic acid, and various tonics, with the usual stock remedies for tinnitus. Pilocarpin was tried in a certain proportion of the cases in which it might with any stretch of credulity be supposed that this most empirically used of otological remedies might benefit. Of galvanism I have had little experience either in diagnosing nerve deafness or healing it. I am perhaps ignorant enough, sceptical enough, or correct enough, not to believe in it. What I do believe in, in the class of cases to which I have referred, can be condensed into a few sentences.

Children of parents affected with deafness should have special attention paid to the ears during the exanthemata.

Adenoids should be carefully looked after, and any nasal deformity that may exist. All through life, if the person should be exposed to such predisposing causes as those I have enumerated in this paper, any slight tinnitus or deafness should have immediate attention, and the children of deaf parents going to reside in the tropics or in miasmatic or malarial climates ought to be warned of the additional risks they run by so doing. The same remark holds good regarding pregnancy or mental over-strain or the infection of syphilis.

I believe the time of the menopause to be a critical time to those women with any tendency to nerve deafness. So is, in both sexes, the time of puberty to those predisposed to hereditary aural mischief. In short, while I attach the greatest importance to prophylaxis and early attention to general hygiene, climate, and to any defects of the middle ear, including the naso-pharynx, with the administration of suitable therapeutic remedies, I think the risk we run as aurists is of abandoning ourselves to fads and quackery in the treatment of deafness due to actual disease of the auditory nerve.

Dr. MILLIGAN (Manchester) was of opinion that cases of pure labyrinthine disease were comparatively rare. In many so-called cases of nerve deafness the origin of the trouble was really in the middle ear. In such cases there was at times slight diminution of the bone conduction, but careful investigation will frequently show that there is better hearing in a noise, which he considered a most important clinical symptom. In cases where definite organic changes had occurred in the nucleus or in the auditory nerve, he did not believe any improvement took place under treatment. His experience in the use of pilocarpin in nerve deafness was most disappointing.

Dr. THOMAS BAER (Glasgow) referred to the importance of examining thoroughly the middle ear, and if any pathological condition was found to exist to treat it by suitable remedies, as even when the symptoms point to labyrinthine disease, treatment of the middle ear might effect improvement. His experience of pilocarpin had not been favourable. The effect of the application of tones of a pitch as far removed as possible from that of the subjective sound upon subjective tumult was very interesting. Unfortunately the improvement was only temporary.

Mr. ROBERT WOODS mentioned a case of sudden and complete deafness both to aerial and osseous conduction in a man suffering from secondary syphilis; neither mercury, iodide of potassium, or pilocarpin had the slightest effect.

Mr. BENNETT had tried pilocarpin in ten cases of congenital syphilis. In two there had been a slight improvement after the first two injections, but it had not continued; in one case, however, there had been decided improvement after several injections had been given on alternate days.

Dr. WARDEN (Birmingham) believed that it was too soon to decide on the value of pilocarpin in labyrinthine disease. He generally preferred the iodide of potassium, followed by tonics. Dr. Macnaughton Jones had referred to a residence in India as a cause of nerve deafness; it was a question he (Dr. Warden) thought, if the frequent use of quinine might not be responsible for it.

Mr. FIELD agreed with Dr. Dundas Grant and Dr. Macnaughton Jones that the present treatment of nerve deafness was unsatisfactory. It was very difficult to diagnose those cases which derived benefit from pilocarpin, although he was sure that a certain number of patients did vastly improve under the treatment, but he was bound to say that many cases which seemed suitable failed to get any benefit. He, however, believed that we should be able shortly to select with greater certainty the cases of nerve deafness that would improve under pilocarpin.

Dr. EDWARD LAW drew attention to cases of nerve deafness in patients with a syphilitic history, and to the fact that mercury whilst relieving the other symptoms, had little or no effect on the deafness. In 3 cases he had observed slight improvement under pilocarpin, in 2 there had been slight relief from distressing tinnitus, and in 1 the hearing was said to be a little better.

Dr. LEWIS JONES stated that he had carried on the elec-

trical treatment in cases of nerve deafness for Mr. Cumberbatch, Dr. Dundas Grant, and others with results which, as might be expected, had been conflicting. The various causes of nerve deafness accounted for this. Of the power of controlling the state of nutrition in sensory end organs by electricity not very much was yet known. The nerve trunks, on the other hand, appeared to respond well to electrical treatment, and neuritis in ordinary mixed nerve was certainly improved by electricity. The favourable cases which occurred from time to time in electrical treatment of disease of the optic and auditory nerve made it probable that a similar useful effect could be produced in the nerves of special senses. He had had a few successful cases. The deeply-seated position of the auditory nerve made it difficult to reach by electrical currents, for the current might already be felt very strongly at the surface, and yet be so diffused before reaching the nerve as to be practically ineffective there. The battery current should be used, and not the induction coil; a bifurcated electrode resembling a binaural stethoscope should be employed; and perhaps it was as well to treat both ears at once, even if one were much more affected than the other. By doing that the patient was made less giddy, and bore the treatment better. The cathode should be applied to the ears. By using large pads of wet cotton-wool, 10 or 15 milliamperes could be borne, and the auditory nerve be appreciably influenced. The current should be half the strength when interruptions or reversals of current were to be employed. These were, in his opinion, useful. With a more perfect classification of the various kinds of nerve deafness it would probably be possible to sort out from the mass cases favourable and cases unfavourable for electrical treatment. Certainly, in electricity there was a good means of profoundly influencing the state of nutrition of a part.

The President (Sir William Dalby) laid considerable stress on the fact that this occasion gave the opportunity of an expression of opinion which was really of a most weighty and important character. Two points stood out in unusual prominence, namely, that the injection of pilocarpin in the opinion of those present was condemned as useless and unjustifiable; and secondly that the result of the treatment of nerve deafness by electricity in the present condition of our knowledge was most discouraging.

Dr. Macnaughton Jones, in reply, said that he first employed pilocarpin for deafness in 1878 in a case of Ménière's labyrinthine vertigo following syphilis. It had done good in that particular instance. He soon found that its clinical benefits in nerve deafness were very limited. He considered its use altogether unjustifiable in a large proportion of the cases in which it had been used. In recent intralabyrinthine effusions, in cases of hypertension of the membranous labyrinth, with increase of either endolymph or perilymph, in recent syphilitic cases, in recent apoplectic seizures, and in leukemic cases, it was of service. We might take the effect of pilocarpin in glaucomatous and other states of the eye as an indication of what we might expect from it in nerve deafness. With regard to galvanism, he would rather attach importance to its proper application as a diagnostic test of nerve involvement than as a means of treatment. He would insist on the fact that many cases of so-called "nerve deafness" were functional. This accounted for the surprising recovery in certain instances. On the other hand a large proportion of these patients had gross middle-ear changes, and were also subject to tubal complications, the treatment of which was followed by considerable improvement. He thought that a large class of mental sufferers from nerve deafness were most benefited by simple hygienic treatment, specially adapted to the particular source of the mental disturbance. He believed in the treatment of early syphilitic cases by timely specific remedies, with pilocarpin, and subsequently iodide of potassium, or other iodides. With regard to what Dr. Warden had said in reference to India and quinine, he would point to intermittent fever and malaria as most potent causes of either primary or secondary nerve deafness, and the doses of quinine, from the known effects of the drug on the circulation of the labyrinth, was a matter for careful consideration in its administration.

The number of workers now engaged in original research at the Conjoint Laboratories of the Royal Colleges is fifteen.

TUBERCULOUS DISEASE OF THE MUCOUS MEMBRANE OF THE MIDDLE EAR AND ITS ADNEXA; AN EXPERIMENTAL INVESTIGATION.¹

By WILLIAM MILLIGAN, M.D.,

Senior Assistant Surgeon, Manchester Institution for Diseases of the Ear; Senior Assistant Physician, the Manchester Hospital for Diseases of the Throat; Lecturer upon Diseases of the Ear, Owens College.

TUBERCULOUS disease of the mucous membrane of the middle ear and its adnexa may present itself either as a primary or as a secondary affection. The paths along which tubercle bacilli may travel to reach the middle ear are: (1) along the Eustachian tube, (2) along the blood vessels and lymphatic channels of the tympanic mucous membrane, (3) through a previously-existing perforation in the membrana tympani.

The Eustachian tube probably acts frequently as the channel along which bacilli are conveyed. It may act in a mechanical manner merely as the path along which they pass, or its mucous membrane being itself the site of tuberculous infiltration, may affect the middle ear secondarily as the result of the extension of the morbid process. Tuberculous affections of the middle ear are probably most frequently secondary affections, secondary, for example, to tuberculous disease of some internal organ, for example, of the lungs or larynx.

In such cases invasion of the tympanic mucosa may take place either as an acute or as a chronic process. In the former rapid cellular infiltration, followed by equally rapid necrosis and caseous disintegration of the mucosa occurs while tubercle bacilli may be found in the discharges from the middle ear in considerable numbers.

In the more chronic form miliary tubercles, which may at times be seen with the naked eye, are deposited within the substance of the mucous membrane. These deposits at an early stage of their existence become caseous and form superficial ulcers. Fresh inoculation takes place in the deeper layers, with the result that it becomes gradually thickened, and may, by a process of fibrous tissue formation, bring the morbid process to an end. More usually, however, extension to the bone takes place, producing a rapid cario-necrotic condition with subsequent opening up of the cavity of the internal ear, extension to the mastoid process or to intracranial structures.

It must not be assumed, however, that every case of suppurative middle-ear disease occurring in a patient already the victim of tuberculous disease elsewhere is necessarily therefore of a tuberculous nature; nor, on the other hand, must it be taken for granted that because tubercle bacilli are not found in the discharges from the middle ear in any given case that therefore the affection is non-tuberculous in nature. Most observers have found it extremely difficult to detect bacilli in pus coming from the cavity of the middle ear, and my own observations fully bear this out. Nathan,² in an examination of 40 cases of purulent middle-ear disease, found tubercle bacilli 12 times. In but 3 of these cases were there no signs of pulmonary phthisis, but in these 3 carious processes were present. According to Habermann³, in certain cases of undoubted tuberculous disease of the middle ear no bacilli were found. Thus, in an examination of the ears of 21 patients suffering from tuberculous lesions of internal organs he could only distinguish the tuberculous nature of the ear affection in 5 cases. In these 5 the mucous membrane of the middle ear was swollen, and studded with occasional groups of giant cells containing bacilli. That a primary tuberculous affection of the middle ear may occur is admitted, although it is usually looked upon as of comparatively infrequent occurrence. It is extremely important, however, both from a scientific and from a clinical point of view, to be able to state definitely whether any given case is or is not of a tuberculous nature. Clinically the co-existence of certain symptoms goes far to prove that certain cases are tuberculous in origin. For example, the sudden onset of a purulent discharge, unaccompanied by any of the usual symptoms of a sthenic inflammation, and the occurrence of a perforation covered by a creamy secretion in the centre

³ Zeitschrift für Ohrenheilk., Bd. vi.

of a pale, cedematous, and uninfamed membrana tympani should always excite suspicion. In addition, the general appearance of the patient, the family history, and the possible presence of other tuberculous lesions may help in establishing an opinion as to the real nature of the inflammatory process. Scientific accuracy is, however, still wanting, although even the surgeon may have a strong suspicion that the case is really one of tuberculous disease.

The great practical difficulties encountered in finding bacilli, either in the discharges from the middle ear or in the tufts of granulation tissue so frequently present in such cases, probably accounts for the few published records of well-authenticated cases. The quest for the bacillus of tuberculosis has proved frequently so tedious and so discouraging that I have in preference selected the method of subcutaneous inoculation as practised by Villemin and Delépine with a view to ascertain, if possible, the real nature of a certain class of case frequently met with in both hospital and private practice. If, with the proper precautions to be presently detailed, artificial tuberculosis can be set up in animals, the inference which one may fairly draw is that the material used for inoculation was itself of a tuberculous nature. The various observations to be presently described have been carried out in the Pathological Laboratory of the Owens College, and I desire to take this opportunity of thanking Professor Delépine for many valuable suggestions and for his kindly assistance.

As the result of a large number of inoculation experiments Professor Delépine has come to the following important conclusions:

1. That the inoculation method is a method of diagnosis capable of giving results free from any ambiguity.
2. That the negative results obtained from it are nearly as valuable as the positive results.
3. That the positive results give more definite information than the discovery of the bacillus tuberculosis.
4. That definite results should easily be obtained within two or three weeks.

He has also shown that if proper precautions be taken the accidental production of tuberculosis can be definitely excluded. For this purpose his first set of experiments consisted in the subcutaneous and intraperitoneal inoculation of sterilised products (including paper), the animals being kept in cages identical with those used for other experiments and disinfected in the same way. In no case was tuberculosis produced, even after keeping the animals for several months under observation.

Secondly, subcutaneous, submucous, intraperitoneal, and intraocular injections were made of non-tuberculous material, including (1) inflamed tissue from the floor of an ulcer and also portions of an enlarged lymphatic gland; (2) pus; (3) degenerated adrenals; (4) sputum; (5) cultivations of other bacteria. Nothing resembling tuberculosis was obtained in any of these experiments. The material used for inoculation in the following cases has been obtained from scrapings of bone taken from the interior of the mastoid process of patients who from the presence of certain symptoms were probably suffering from tuberculous disease of the middle ear and its adnexa. The investigations have also been carried out in cases which clinically at any rate might fairly be regarded as instances of primary middle ear tuberculosis. For the most part, they have occurred in infants and young children. In every case the most careful examination has failed to detect any evidence of tuberculous disease in the chest or abdomen.

Schwarze¹ declares that primary tuberculosis of the middle ear or of the mastoid process is an eminently rare affection, in the diagnosis of which we cannot be too reserved or distrustful. Zaufal² has described two cases of primary tuberculous disease of the ear. In the one a localised mass of tubercle was found in the pars petrosa of the temporal bone, in the second the internal auditory meatus was blocked by a mass of tuberculous tissue. Knapp³ has also described a case of primary tuberculosis of the mastoid process occurring in a patient aged 5 years, where both tympanic membranes

and both middle ears were perfectly normal as far as physical examination could discover. In this case, however, the diagnosis was made upon purely clinical grounds.

Few published records of undoubted primary tuberculous lesions of the ear are found in literature, but may not this be due to the omission either of special bacteriological investigation or to the performance of inoculation experiments?

In the following experiments guinea pigs were used for the purpose of inoculation. The left hind limb was carefully shaved, washed with sublimate lotion, and then gently singed with a flat platinum knife at a white heat. A small pocket was then made under the skin at about the level of the knee joint with a freshly sterilised knife, and into this pocket a scraping of bone from an affected mastoid was introduced with freshly sterilised forceps. A piece of plaster was then placed over the wound, and the guinea pig put back into its cage and closely watched for from three to six weeks, during which time the animal was well looked after and well fed. The greatest possible care was also taken to perform the mastoid operation with the most rigid aseptic precautions. Freshly sterilised instruments were always employed. The skin around the ear having been well washed, the diseased mastoid was opened in the ordinary way, and a scraping of bone taken from an area where disease was seen to be advancing was removed, and immediately placed in a sterilised tube. The inoculation of the guinea pig was performed upon the same day as the operation, or at the latest upon the following day, the sterilised tube being meanwhile kept in a cool place. Throughout the investigation every precaution was taken to avoid any accidental contamination of instruments or of material.

The results obtained are somewhat striking, and prove, I think, that primary tuberculous disease of the middle ear is a much more frequent condition than is usually supposed to be the case. Thus, of the 10 cases to be described, 8 (or 80 per cent.) were of a tuberculous nature; 2 (or 20 per cent.) were non-tuberculous.

The clinical picture presented by most of the cases consisted in the sudden and apparently painless onset of discharge from one or both ears, the early involvement of the glands around the auricle and the frequent presence of facial paralysis.

The amount of discharge was usually fairly profuse, was at times sanious, and at an early stage became markedly foetid. In addition flabby granulation tissue blocking the external auditory meatus, and evidently connected with a rapidly disintegrating bone, was found in 9 out of the 10 cases. The rapid and marked implication of the glandular structures around the ear suggested something more than a simple inflammatory process, while the early involvement of the facial nerve, in my experience at any rate, a by no means usual symptom in recent cases of simple inflammatory origin, appears to me to be a symptom worthy of consideration.

Cases presenting such symptoms, although they may be looked upon as being probably of a tuberculous nature, require for confirmation either the discovery of the bacillus tuberculosis in the aural discharges, or the establishment of a general tuberculosis in animals inoculated with material from the affected ear.

CASES.

1.—J. C., male, aged 10 months, was brought to hospital on account of the presence of an offensive discharge from both ears. According to the mother's statement the discharge was first noticed when the child was 4 weeks old, and apparently both ears had become simultaneously attacked. When first seen the following notes were made: "right and left meati full of foul smelling pus." After syringing examination showed both meati blocked with pale and unhealthy looking granulations. Palpation with the probe showed that the posterior meatal wall was bare and eroded, and exposed bone was felt in the depths of the ear. The glands immediately beneath the auricle were enlarged and tender. No external appearances of mastoid disease were apparent, no edema, no tenderness. The child was pale and ill-nourished, perspired a good deal at night about the head, and was usually very restless.

Family History.—Father and mother alive and healthy. Family consists of three children; the two eldest have always enjoyed good health; the third child, the patient, has never been strong, both ears having commenced discharging shortly after birth.

Operation was advised. A few days afterwards the child was put under chloroform, and the usual mastoid incision was made. After resecting the two sides of the incision, and so exposing the mastoid cortex, a fistula the size of a threepenny bit was immediately brought into view. With a small spoon a considerable amount of cheesy debris was scooped out, and a large cavity in the mastoid process thus exposed. This was carefully curetted until all diseased tissue was considered to have been cleared

out. The bridge of bone separating this cavity from the external meatus was now broken down, and so the cavity in the mastoid process, the cavity of the middle ear, and the external meatus were thrown into one. The parts were then carefully dried, dusted freely with iodoform powder, and packed with iodoform gauze. The usual dressings were then applied.

The macroscopic appearances of the part were such as to make one suspect the presence of a tuberculous process. The left ear was accordingly during the following fortnight simply syringed with plain warm water, and a fortnight subsequently the child was again put under chloroform and the left mastoid process opened. All the instruments used during this second operation were most carefully sterilised, and were in fact removed straight from the steriliser for the immediate necessities of the operation. When the edges of the incision were retracted a precisely similar condition of affairs was seen as had been found to exist upon the right side. After the removal of some of the more superficial debris small scrapings were taken from the bone at three different levels. These scrapings were immediately placed in sterilised test tubes. The same afternoon three guinea pigs were inoculated with this material, the inoculation being made in each case into the subcutaneous tissues of the left hind limb at above the level of the knee-joint. A fortnight afterwards each of the three guinea-pigs was found to have distinctly enlarged superficial inguinal glands.

Dissection of guinea pig to show enlargement of the glands following subcutaneous inoculation with tuberculous material taken from the mastoid process of a child. X indicates the site of inoculation.

Towards the end of the fourth week the ganglia of both fore limbs and also the cervical ganglia were affected. Five weeks after the inoculation had taken place the guinea-pigs were killed and were at once dissected. The accompanying figure shows the glands as they are found five weeks after the subcutaneous inoculation of tuberculous material. Besides enlargement of the inguinal glands, superficial and deep, the popliteal, the sublimbar, the retrohepatic, and the peri-bronchial glands upon the same side as the lesion, were found markedly enlarged. In addition the spleen was found freely studded with tubercles, and a few were scattered here and there in the liver and lungs. (See figure.) Scrapings were taken from the interior of the sublimbar gland and stained for tubercle bacilli according to Seaton's method, with the result that considerable numbers were found in several cover glass preparations. Both mastoid wounds were carefully treated. Iodoform was freely used as the dusting powder, and iodoform gauze as the material for packing. Gradually the cavities began to granulate, until finally complete filling took place. When last seen, seven months after the operation, a firm, although considerably depressed, mastoid cicatrix marked the site of the original wound upon each side. No pus was found either in the external meatus or in the middle ear. The membrana tympani upon both sides showed a large dry perforation, but no trace of the ossicula could be seen.

11.—J. G., aged 3 months, was brought to hospital with the statement that the right ear had been discharging for a few weeks. The right

external meatus was found full of foetid pus. After syringing, fleshy granulations were seen to be present, and examination with the probe detected an extensive area of parietal caries. A large mass of glands was found immediately below the auricle, and careful palpation over the mastoid process made it probable that an area of softened bone existed.

Family History.—Father and mother alive and healthy. Father had one brother, who died of phthisis. The family consisted of two children. The elder of the two died when 6 months old from convulsions.

Operation was advised, and was performed one week later. In the interval the ear was kept as clean as possible by frequent syringing with plain warm water. The usual mastoid incision was made, and the edges having been retracted a small fistula was found upon the surface of the mastoid cortex. This was gradually enlarged by means of a Volkmann's spoon, and a considerable quantity of foul-smelling cheesy debris removed. A scraping from the edge of the bone where the disease appeared to be advancing was taken and immediately transferred to a sterilised test tube. The same afternoon a guinea pig was inoculated with this scraping in the manner previously detailed. Five weeks later the guinea-pig was killed and dissected. The same glands were found enlarged as in the previous case. A scraping was then taken from the deep inguinal gland, stained for tubercle bacilli, and placed under the microscope. Several bacilli were found. The patient was treated just as in the last case, and for a time good progress was made. A large abscess, however, formed round the left hip-joint. This was accompanied by great prostration and considerable rise of temperature. The child was removed to another hospital, where this abscess cavity was laid open. Symptoms indicative of tuberculous meningitis suddenly set in, and the child died partly as the result of marasmus and partly from the effects of frequently repeated convulsive seizures. Unfortunately no post-mortem examination could be obtained.

12.—R. B., female, aged 8 months, was seen in consultation on account of a constant purulent and foetid discharge from the left ear. The child had become very restless during the preceding three weeks, and was also exhibiting somewhat rapidly. Examination showed that the left external meatus was full of foul-smelling pus. After this had been removed a mass of granulation tissue was detected deep down in the meatus. Palpation with a probe revealed the presence of extensive caries. The glands below the ear were enlarged and tender. No external evidence of mastoid disease was apparent.

Family History.—Father and mother alive and healthy. Of the two sisters, one had suffered from enlarged tonsils, naso-pharyngeal adenoids, and enlarged cervical glands; the other was apparently quite healthy.

Operation was advised and undertaken a week later. The mastoid process was opened in the usual way, and the cavity thus exposed, the cavity of the middle ear, and the external auditory meatus were thrown into one. A considerable quantity of cheesy debris, softened bone, and fleshy granulation tissue was removed. The parts were well dried, dusted with iodoform powder, and dressed in the usual manner. A scraping from the bone was placed in a sterilised tube, and a guinea-pig was inoculated. General tuberculosis was set up, and after six weeks the animal was killed. Scrapings from several of the glands were taken and examined for bacilli, with the result that considerable numbers were found.

13.—E. B., female, aged 8 months, was seen in consultation with Dr. Byrne of Chorlton-cum-Hardy, on account of a profuse foetid discharge from the left ear. The history given was that the child's ear had begun to discharge when she was 4 months old, and that there had been a continuous discharge ever since. Shortly after the ear trouble had commenced the glands below the ear began to enlarge, and when the child was first seen a large mass of hard indurated glandular tissue was found in this situation. During the preceding three weeks well marked left-sided facial paralysis had been observed. The child was very restless at night, and perspired freely about the head. On two or three occasions the child had had convulsive seizures. Upon examination the left auditory meatus was found full of granulation tissue, and palpation with the probe revealed the presence of an extensive area of exposed bone. The tissues over the mastoid process were infiltrated, and offered a certain doughy resistance to palpation.

Family History.—Father and mother alive and healthy. Mother has had only one child. The father's family history was good. The mother's parents are alive and healthy. The family consisted of five sons and five daughters. One son died at the age of 9 years of "decline," and one daughter died at the age of 22 of "tuberculous meningitis." The other sons and daughters are alive and healthy.

Immediate operation was advised. Two days afterwards the child was put under chloroform and the usual mastoid incision made. After the flaps had been retracted, the mastoid process was opened in the usual way, and cheesy debris and unhealthy-looking granulation tissue freely removed. The operation was conducted just as in the previously mentioned cases, and a scraping of bone was removed for inoculation purposes.

For the first few days good progress was made. Shortly afterwards, however, the child was again seized with severe convulsive seizures. The temperature rose, and a frequent meningeal cry was heard. At the post-mortem examination the lungs, liver, kidneys, and spleen were found to be perfectly normal. The glands around the ear were in a state of early cheesy degeneration. Description of middle ear: The membrana tympani was entirely gone. The stapes was the only ossicle left. The mucous membrane was pale and oedematous, and upon examination with a lens several tubercles were seen.

Upon opening the cranial cavity a small quantity of fluid escaped. The vessels of the pia-arachnoid about the base of the brain were found congested, and several groups of small tubercles were found in the meshes of the pia-arachnoid upon the same side as the diseased ear.

The guinea-pig which had been inoculated with a scraping of bone from this case became rapidly tuberculous, and when killed six weeks afterwards showed involvement of the various glands as seen in the accompanying diagram. Scrapings taken from these glands and stained for tubercle bacilli revealed their presence, and microscopic sections of pieces of liver and spleen showed well-marked giant cells. In addition, two tubes of agar agar were inoculated with material taken from the diseased glands and pure cultivation of the tubercle bacillus produced.

14.—H. B., male, aged 3 years, was admitted to hospital under the care of my colleague, Mr. Pinder, who was good enough to allow me to see

the case. The history given was that the right ear had commenced to discharge when he was 4 months old, and had discharged ever since. Upon admission, the right external meatus was full of thick pus, and bare bone was readily felt by means of the probe. A fortnight before admission the child had fallen and injured the right hand, which now presented the typical appearances of tuberculous infiltration of the second metacarpal bone. For many months also he had had an enlarged testicle, which during his stay in hospital suppurated.

Family History.—Father and mother alive and healthy. One other child, also healthy. No family history of tubercle.

The right mastoid process was opened under chloroform, and a large quantity of purulent debris and necrotic tissue scraped out. A scraping was taken and used for an inoculation experiment. Five weeks afterwards the guinea-pig was killed, and scrapings taken from the diseased glands and stained for bacilli showed their existence in considerable numbers.

VI.—B. A., male, aged 11 years, had suffered from left-sided, purulent, middle-ear disease for many years. When admitted into hospital he was found to have a large subperiosteal mastoid abscess upon the left side, a meatus blocked with granulation tissue, and an extremely offensive discharge from the ear. For some days before admission he had suffered from severe pain in the head, and had had several rigors. Under chloroform the subperiosteal abscess was opened, and a fistula found in the mastoid cortex. After enlarging this a large cavity was found filled with cholesteatomatous and purulent debris. When this had all been scraped out the dura mater was found exposed for an area of about the size of a shilling. The surface was dark coloured and sloughy. The cavity was well washed with weak bichloride solution and packed with iodoform gauze. The patient made an uninterrupted recovery. Scrapings taken from the mastoid and placed under the skin in a guinea-pig's left hind limb about the level of the knee-joint produced a localised area of suppuration, and a small abscess formed, but quickly healed. Each week the animal was carefully examined, but no enlarged glands could be detected. Six weeks after the inoculation experiment the animal was killed. The organs were found quite healthy. There were no enlarged glands and no evidences of tuberculous deposit anywhere.

VII.—H. C., male, aged 7 months, was brought to hospital with the following history. When 3 months old the left ear began to discharge. Very shortly afterwards the glands below the auricular attachment were found enlarged and painful, and about this time (a month after the commencement of the trouble) complete left-sided facial paralysis developed. Upon examination the meatus was found quite blocked with unhealthy-looking granulation tissue, and extensive cario-necrosis was easily demonstrated to be present. There was no external evidence of mastoid disease.

The family history showed nothing of importance. The child was an only child. The mother came of a healthy family; the father also was healthy, but was addicted to drink. A mastoid operation was performed just as in the previously detailed cases, and considerable quantities of softened bone and caseous debris were removed. A scraping of bone taken from the advancing edge of the disease was removed and used for inoculation purposes. Six weeks afterwards the guinea-pig was killed, and found to present the appearances of advanced tuberculosis. The glands were enlarged, and on section were cheesy. The spleen was packed with tubercles; many were also found in the liver, and a few in the lungs and kidneys. Scrapings from the glands stained for bacilli revealed their presence in considerable numbers.

VIII.—G. C. T., male, aged 2½ years, was seen in consultation with Mr. Mallin, of Rochdale, on account of the presence of a purulent discharge from the right middle ear, which had persisted for six months. The left ear had also been discharging, but at the time of the consultation was found perfectly dry and the membrane cicatricial. Examination of the right ear showed that Shrapnell's membrane was perforated, and that a small tuft of granulation tissue protruded through the opening. The probe demonstrated the presence of bare bone upon the posterior meatal wall and upon the roof of the middle ear. For a few weeks local treatment was tried. The tuft of granulation tissue was removed, and various astringent and antiseptic lotions were used. No real progress was however made, and as the tissues over the mastoid process became suddenly red and puffy an immediate operation was advised. The patient was put under chloroform, and the usual incision made. Upon opening the process much purulent debris and granulation tissue was found. This was all carefully scraped out and the cavity packed with iodoform gauze. At first the patient made good progress, but shortly afterwards the wound became very sluggish and refused to heal. The cavity was accordingly again scraped, and this time finally healed. When last seen a depressed mastoid cicatrix marked the site of the previous operation wound; the middle ear was quite dry, and the membrana tympani showed the existence of a large and dry perforation. No sooner had the right ear healed, however, than suppuration started again in the left middle ear, and was almost immediately followed by the formation of a subperiosteal mastoid abscess. When this was opened a minute fistula was found leading into the interior of the bone. The fistula was at once enlarged, and the operation conducted as in the previously detailed cases.

Inoculation made from scrapings taken from the left mastoid process was followed by the typical development of well-marked tuberculosis.

IX.—J. C., male, aged 5 months, was admitted into hospital on account of suppuration from both middle ears. The history given was that the child had from birth been very fragile, and at one time appeared to be rapidly emaciating. When 2 months old both ears commenced discharging simultaneously, and had discharged constantly until the time of admission to hospital. Upon examination the child was found to be pale and emaciated. Both ears were discharging freely. Upon the right side a subperiosteal mastoid abscess was found, and upon the left the tissues over the mastoid process appeared quite normal. The glands below both ears were found enlarged.

The family history was negative. Father alive; healthy; addicted to drink. Mother alive and healthy. No other children. Grandfather died of consumption.

Under chloroform the fistula leading into the right mastoid process was enlarged and purulent debris and caseous material scraped out. A

week later the left mastoid process was operated upon. The surface of the bone was dark coloured and sloughy in appearance. The bone itself was very soft and friable, and when opened the process was found to contain cheesy debris. Inoculation made from both mastoids produced typical tuberculosis in two guinea-pigs.

The child never appeared to make any progress after the operation. Severe diarrhoea set in, which no treatment appeared in any way to influence. Symptoms indicative of tuberculous meningitis set in suddenly, and the child died thirteen days after the operation had been performed. No post-mortem examination could be obtained.

X.—B. R., female, aged 19 years, had suffered from left-sided purulent middle-ear disease for many years. Examination showed that the left membrana tympani was almost completely destroyed, and bare bone was felt with the probe upon the posterior and superior walls of the middle ear. As ordinary methods of local treatment had been tried without avail, it was decided to perform a mastoid operation according to Hackett's method. This was accordingly done, and a scraping of bone was removed and used for inoculation purposes. The guinea-pig showed no signs of developing tuberculosis, and when killed six weeks afterwards, no enlarged glands and no deposits of tubercle in the liver or spleen could be detected. A slight inflammatory thickening round the site of the inoculation was found.

In the treatment of these tuberculous lesions where considerable destruction of bone has taken place, it is advisable to open the mastoid process at as early a date as possible, to scrape away all softened and caseous debris, to make free communication with the cavity of the middle ear and external auditory meatus, and to keep the parts well packed so that the process of granulation may proceed *ab initio*. Free dusting with iodoform powder has seemed to be beneficial. At times, when the granulating surfaces have shown a tendency to become sluggish, swabbing with chloride of zinc (gr. xv to ʒi) has materially expedited matters. Great attention must also be paid to the state of the general health of the patient. Tonics such as syr. ferr. iodidi, syr. iodidi, cod liver oil, etc., should be freely administered, while at the same time plenty of good milk and farinaceous food should be given. When circumstances admit, residence at the seaside or in good bracing country air should be ordered.

THE TREATMENT OF INTRACTABLE SUPPURATION OF THE MIDDLE EAR BY OPERATION THROUGH THE MASTOID,

BASED UPON EIGHT SUCCESSFUL CASES.¹

By THOMAS BARR, M.D.,

Lecturer on Diseases of the Ear, Glasgow University.

THE present paper is based upon eight cases of chronic purulent inflammation of the middle ear, which, after the employment of all the ordinary methods of treatment through the external auditory canal and Eustachian tube, continued for months, and even years, were successfully operated upon through the mastoid. Four of these cases were operated on by Dr. Macewen and four by myself. Two were in the right ear and six in the left. Instead of describing these cases in all their clinical details, I prefer simply to place before you the salient points from which you may be able to judge of their significance:

1. In these eight cases the purulent mischief had been of very long duration. The duration of the shortest was three years, the others extended from fourteen to twenty-two years.

2. In every one, treatment through the external meatus and Eustachian tube had been previously carried out, in no case for less than a year, and in some for as long as seven years.

3. In none of the cases did the secretion before operation ever lose the odour of decomposition.

4. In every case the seat of the purulent formation was without doubt chiefly in the attic or attic and antrum, either with perforation in Shrapnell's membrane, or other clear evidence that the essential mischief was in these regions.

5. In no case were there any objective signs of mastoid complication.

6. In all the attic syringe had been employed, and in three cases the malleus had been removed in order to allow of more efficient treatment of the attic.

¹ Read in the Section of Otolaryngology at the Annual Meeting of the British Medical Association, held in London, July-August, 1895.

7. In regard to age and sex, the youngest was 14 years and the oldest 32 years; six were males and two females.

METHOD OF OPERATING.

The operation in each case was performed with the globular dental burr, supplemented by a gouge, as first suggested by Dr. Macewen. In regard to this method of operation, it is very important to employ burrs which are very hard and sharp, and those made at Philadelphia were found to be much the best. A dental engine of considerable power, either worked with the hand or foot, is required. The hand piece is held like a pen, and the lateral part of the burr is applied to the bone, which, as the burr rapidly rotates, is raised in flakes. To prevent excessive heat developing, as well as to allow of inspection of the parts, the burr should be momentarily removed every few seconds. It is possible with the instrument to avoid wounding any structure in however close proximity it may be. As Dr. Macewen observes, dark apertures, or a membrane such as a pyogenic membrane, or the sigmoid sinus or dura mater, are readily seen on the white polished surface made with the burr. By this mode of operating, even although there may be an abnormality in the relative positions of the interior of the cranium to the outer parts, the dura mater or lateral sinus need not be injured, although exposed. In one of these cases I encountered the sigmoid sinus, but this did not stop or interfere with the progress of the operation. In another the dura mater on the floor of the middle fossa was exposed without the least untoward result. In most cases the cortical substance was found to be very thick and hard, the cells being partially sclerosed, and converted into an ivory-like substance, the penetration of which was very difficult, and occupied considerable time. In some cases the operation was expedited by the use of a sharp gouge, if the bone were not too hard. The antrum was sometimes found surprisingly high up, even above the level of the linea temporalis, and deeply situated. In one case it was extremely small. The walls of the antrum were generally very hard, so that the strongest gouge produced little impression upon them, although the burr could always rub them down. When the antrum was freely opened, and all the morbid material removed or scooped out, the antro-tympanic passage under the roof of the middle ear was exposed by the cautious working of a small burr, so as to enable us to clear out from this space with small scoops and forceps not only the inflammatory products found therein, but also the malleus and incus, if these were found. When the tympanic cavity was situated far forward, it was not an easy matter to reach and explore it; it was then necessary to remove the postero-superior wall of the canal, or at least a portion of it (modified *Stake's* operation). While working in this deep region, a reflector on the forehead was essential, with good artificial or natural light. The corresponding side of the face was carefully watched, so as to detect the slightest twitch which might indicate dangerous proximity to the facial nerve; but by keeping well up and avoiding the inner wall of the antro-tympanic passage, this nerve was in no case in the least degree injured.

AFTER TREATMENT.

After the thorough removal, by means of syringing with antiseptics, of all disease products as well as the pulverised bone, the dry treatment was in the first place adopted. The spaces were filled with powder of iodoform and boracic acid (one of the former to four of the latter) and stuffed with gauze. A wood-wool pad, with an aperture for the auricle was placed over mastoid and side of head, and a bandage over all. In the absence of moisture through the dressings the parts remained undisturbed for a week, and sometimes for a fortnight, when, if moisture appeared, the powder and stuffing were removed, with or without syringing the cavities. Dr. Macewen preferred the dry treatment, but I found that unless the secreting process ceased entirely and early, the continuance of the dry treatment with infrequent dressing was not satisfactory. No doubt, if it were always possible to remove every trace of disease the dry treatment would be the ideal one, but with the conditions existing in the temporal bone in such cases this is not always possible. I have found, therefore, after the first two or three dressings that careful and regular antiseptic cleansing has been required for weeks and even months. A watery solution of carbolic acid or boracic acid was injected

once or twice a day through the opening in the mastoid into the external auditory canal, and *vice versa*. A spirituous solution of carbolic acid or boracic acid poured in or injected after the syringing appeared to be sometimes beneficial. In some, after the use of this for a time, one insufflation of finely-powdered boracic acid blown into the canal and into the artificial opening seemed to bring the secreting process to an end. I had in some cases to discontinue iodoform owing to its producing severe eczematous inflammation in the neighbourhood of the wounds. The cavities were always stuffed with gauze and in the mastoid opening granulation tissue had in my cases to be scraped away with the sharp spoon or touched with chromic acid.

RESULTS.

Of these eight cases, the first was operated upon on June 19th, 1893, the last on December 17th, 1894. In six cases the operation achieved ultimately the desired effect of bringing the discharge to an end, and in no case has there been up till now any recurrence of the discharge. In the other two there is scarcely a trace of secretion, only requiring syringing once a fortnight. The longest period which has elapsed since the establishment of the non-secreting condition has been fifteen months, and the shortest three months. From the operation to the entire cessation of discharge the time varied in the different cases from two months to eighteen months. In three cases very little discharge appeared at any time after the operation, and certainly within three months there was no indication whatever of a purulent process. In one case the dry condition was brought about six months after the operation, and in two cases the secretion had not entirely ceased until eighteen months had elapsed. Of the two still showing a very faint trace of odourless secretion, six months have elapsed since the operation in one and a year in the other. I think that, with larger experience of this operation, the time between the operation and the cure of the discharge will become much shorter. In one case two operations were performed: the first on February 26th, 1894, and the second in October, 1894. In the first the antrum was opened and a portion of the inner end of the canal was removed, while in the second operation the whole of the postero-superior wall of the canal was taken away with the outer walls of the antrum and attic ("Kuster's operation").

With respect to the artificial opening, it was found in certain cases difficult to maintain it for a sufficient length of time, owing to its tendency to contract in spite of thorough stuffing with gauze. I found, however, that while premature closure should be avoided, it was on the other hand not desirable in all cases to insist upon the maintenance of the opening till the discharge ceased. In 2 cases I found that only after the healing of the mastoid wound did the secreting process in the ear entirely cease. In other cases the opening readily remained as a tunnel-shaped passage leading into the antrum and attic becoming partially lined with epidermis, and non-secreting. In 4 cases out of the 8 the opening still remains. In one the canal leading to the attic still exists, a year and a-half after the operation. It is quite dry, partly lined with epidermis, and is kept occupied with gauze. In other 2 the opening behind has not yet, six and eight months respectively after the operation, been allowed to close, although quite superficial and perfectly dry. In the fourth, in which the whole postero-superior wall of the canal and the outer wall of the antrum and attic were removed, the external opening corresponds with the bony meatus, and leads into a cavity which has considerably contracted; it is perfectly dry and occupied by gauze.

In regard to the fate of the ossicles, the malleus was removed in 3 cases previous to the operation, and in 2 of these the incus was found between the attic and antrum, and removed. In 3 others the incus was removed at the operation, diminished in size by caries. In 1 case neither ossicle was found.

With regard to the effect on the hearing power. In 1 case the hearing was notably improved; in 3 cases it was slightly improved; in 2 it was unaltered; in 2 the deafness was increased after the operation.

In concluding, I would emphasise the fact that these 8 cases were not selected from a large series of cases because

of their success. They include without exception all the patients under my care who have been operated upon in this way since June 29th, 1893. The results must be regarded as very encouraging, as in every instance the goal aimed at was attained—namely, the removal of a purulent process in the middle ear and temporal bone, which had for years baffled all other methods of treatment carried out personally by well-known specialists.

Dr. MILLIGAN (Manchester) agreed with Dr. Barr as to the advantage of the burr in the mastoid operation. In the treatment of those cases which depend upon suppurative disease of the tympanic attic he thought that the line of procedure to be adopted should depend upon the exact etiological factors which produce the suppuration. He had found distinct advantage in retaining a permanent mastoid fistula, not only on account of the ease with which the parts might be inspected, but also because he had found in several cases an improvement in the hearing.

A DISCUSSION ON CEREBRAL COMPLICATIONS IN RELATION TO MIDDLE-EAR DISEASE.¹

INTRODUCED BY WILLIAM MACWEN, M.D., F.R.S.,
Regius Professor of Surgery, University of Glasgow.

IN a Section of the British Medical Association so largely consisting of specialists, it is with diffidence that a surgeon, not only addresses them, but ventures to open a discussion. The cordial invitation, however, of the Council of the Otolological Section, so courteously conveyed by your President, Sir William Dalby, caused me to dismiss the hesitancy, and I accede with pleasure to their request to open a discussion on cerebral complications arising from ear disease.

It is evident that the time at our disposal is insufficient to enable us to review even the pathology of the various forms of intracranial complications arising from middle-ear disease. It is necessary, therefore, to select a few points for discussion, without wishing to restrict others who may deem it advisable to introduce subjects which they consider of equal importance.

An opportunity has been afforded me so recently of expressing my views on abscess of the brain, meningitis, and sigmoid sinus thrombosis—the three main forms of pyogenic intracranial invasion arising from otitis media purulenta, that the Section will kindly take as read the observations which I might otherwise have found necessary to have placed before them to-day upon these subjects.

I will therefore direct your attention to three points. First, to a fallacy in differential localising diagnosis; secondly, to tubercle of the middle ear; and, thirdly, to a few points on bacteriology in aural surgery, especially regarding prophylaxis.

A FALLACY IN DIFFERENTIAL LOCALISING DIAGNOSIS.

When in a case of intracranial abscess a difficulty exists in localising the lesion to the cerebrum or cerebellum, it has been averred that the point can easily be decided by testing the function of the nerves to transmission of sound by bone conduction. It is alleged that if bone conduction be still intact the abscess is in the cerebrum, but if bone conduction be absent then the abscess is cerebellar. This statement is evidently based upon *a priori* reasoning, and it is founded upon at least two fallacies.

First, it is assumed that the path by which pyogenic organisms reach the cerebellum and there produce abscess is by way of the internal ear; and, secondly, it takes for granted that a pyogenic infective process spreading along the auditory nerve and its coverings would abolish the possibility of bone conduction. Facts are, however, decidedly against this hypothesis, and do not bear out the assumptions upon which it is founded. First, cerebellar abscess arises, as a rule, from pyogenic extension from the sigmoid sinus, and not by way of the internal ear, so that the seventh and eighth nerves in the internal ear remain unaffected and capable of performing

their function, and if the mechanism of hearing remains intact the auditory will transmit sounds aerial as well as by bone conduction, notwithstanding the presence of cerebellar abscess.

Secondly, even when the internal ear is the path by which pyogenic intracranial invasion takes place, bone conduction may remain intact. A case illustrating this occurred recently, and came under my care, suffering from purulent leptomeningitis, originating in otitis media purulenta. The patient, whose aural conduction on the affected side was almost absent, yet retained the function of bone conduction, which seemed almost more acute on the affected ear than on its fellow on the opposite side. At the post-mortem examination there was extensive purulent lepto meningitis, chiefly marked in the posterior fossa surrounding the right internal auditory meatus. A marked contrast was presented between the appearances of the seventh and eighth nerves on the right side (the affected side) and the corresponding nerves on the left; while the latter occupied about one half of the lumen of the internal auditory meatus; the nerves and their pial coverings on the right side were so swollen that they occupied the whole canal, and were even compressed by the enclosing bone, as the portions of the united nerves, previous to entering into the canal, were more swollen than those inside of the canal. A semi-purulent exudation lined the pial sheaths throughout the course of the internal auditory canal, and was seen to pass outward to the cribiform plate on the one hand and into the internal orifice of the aqueductus Fallopi on the other. The pial sheaths of the lesser petrosal nerves were likewise inflamed, though to a less extent. Yet, while this patient lived she still retained the perception of bone conduction equally on both sides. A still further fact against this theory appeared in a case previously published by me,² in which "the hearing was absolutely abolished by aural and bone conduction, yet there was no abscess in the cerebellum, and there was a superficial one in the cerebrum." Probably in the latter case the abolition of the function of the auditory nerve might have been due to previous chronic processes.

It may therefore be concluded that neither in its presence nor in its absence is bone conduction a reliable sign of localisation between cerebral and cerebellar abscess.

Tubercle of the middle ear in its relation to intracranial lesions has not yet received the attention which it deserves. It is one of the less obtrusive forms of middle-ear disease, spreading slowly, occasioning little pain or uneasiness, and being often accompanied by very slight mucoid discharge. In some cases, also, the disease reaches an advanced stage without occasioning perforation of the membrana tympani, yet its extension to the membranes, especially in children, whose sutures are still open, is always liable to occur. Two such cases have been under my observation. Both died from tuberculous meningitis, and post-mortem examination showed that the invasion of the inner membranes was clearly traceable to the tuberculous focus in the middle ear. The invasion was by direct extension through the ununited petro squamosal suture to the membranes of the middle fossa of the skull. When the inner ear is involved, no doubt the tuberculous invasion proceeds by the pial coverings of the seventh and eighth nerves in the internal auditory canal. The grosser forms of tuberculous otitis media are familiar to every aurist, but they are not so apt to be followed by intracranial tuberculous complications, as in the advanced stages of tuberculous destruction of the middle ear, pyogenic processes are apt to be superimposed, and when this does occur the latter assumes the rôle (to borrow a current phrase) of the "dominant partner." Here, as elsewhere in the body, tuberculous products form excellent cultivation media for pyogenic cocci, which, when they are implanted on them, become vigorous, proliferate rapidly, and disseminate themselves into all the osseous erosions and softened membranes which the tubercle bacilli have been so insidiously and slowly accomplishing. If a breach, however small, can be found in the protective wall of granulation tissue surrounding the softened cerebral membranes, the pyogenic organisms will invade the intracranial cavity. It reminds one of the words which Shakespeare puts into the mouth of Richard III:

¹ In the Section of Otolaryngology at the Annual Meeting of the British Medical Association, held in London, July-August, 1895.

² Pyogenic Diseases of the Brain and Spinal Cord, p. 286.

For within the hollow crown
That rounds the mortal temple of a king
Keeps Death his court; and there the attic sits.....
Allowing him a breath, a little scene,
—and, humoured thus,
Comes at the last, and with a little pin
Bore through his castle wall, and—farewell, King!

Thus, in at least two ways, tubercle of the middle ear merits our attention in relation to intracranial complications, first, by the fact that tuberculous invasions of the membranes of the brain may occur from the focus in the internal or middle ear; and secondly, tubercle of the middle ear, by its slow disintegrating process, lays bare the intracranial contents, and exposes them to attacks of pyogenic cocci whose patency has been increased by the pabulum which the liquefaction of the tuberculous products afford.

Besides invading the cranial contents, tubercle originating in the middle ear and mastoid antrum and cells may enter the circulation, and when it does it occasionally induces military tuberculosis of the lungs or other organ. The possibility of doing so may be judged by the fact that the tuberculous invasion readily passes backward to the sigmoid sinus or inwardly to the recesses of the petrous bone, and even occasionally penetrates the jugular fossa. Then, by the softening of the walls of the smaller, and sometimes also of the larger, vessels, the ensuing tuberculous infiltration finds its way into the blood stream. Tubercle surrounding the sigmoid sinus is in my experience of frequent occurrence, and in the *post-mortem* examination of a patient who died from military tuberculosis of the lungs, the sigmoid sinus was included in tuberculous granulations, and its anterior wall was softened and infiltrated with tuberculous foci, one of them caseating.

Those invasions of other parts of the body are secondary to the primary focus in the ear, and if tubercle of the mastoid antrum and cells is to be treated, it must be on the same footing as one deals with a localised tuberculous lesion elsewhere. Except by way of improving the hearing in such cases a little good would be done by removing a small portion of granulation tissue from the middle ear. The mastoid process must be freely opened, and the whole of the recesses of the temporal bone exposed, and tubercle fully eradicated.

In contemplating the small area occupied by the middle ear and its annexes, one cannot avoid being struck by the potency of the forces which may be generated within, and which, under suitable conditions, may not only invade the intracranial contents, but within a few days may destroy the function of the whole cerebro-spinal system, or, entering the circulation, induce general toxæmia, pulmonary infections, or infective gangrenous pneumonia. The middle ear, and especially the mastoid antrum and cells, while in a state of suppuration, acts as an incubating chamber beautifully arranged for bacteriological work such as the cultivation of the various pyogenic cocci. In it the organisms are supplied with moisture, kept in darkness, afforded abundant pabulum, and are maintained under carefully regulated thermic conditions. The access to some of these chambers is difficult by way of the external auditory meatus, while injections by that route will hardly reach them, and may even do harm by disseminating the elements which one wishes to remove. Some of these cells are filled with cholesteatomatous material, in which cocci are protected and preserved quite proof against the small quantities of antiseptic fluids which may reach it, as these merely play over the surface of the unctuous material without affecting the organisms within.

Besides the organisms contained in this store of solid culture medium others may introduce themselves, or, more probably, be introduced from without. One knows the ease by which organisms may be transferred from one liquid medium to another by merely allowing the point of a slender platinum wire to come in contact for a minute portion of a second with an affected liquid, and then transferring the wire to a sterile medium. So, if it were possible at the present day to find a surgeon who was not scrupulously careful about his examination probe or other instrument, one might expect that the hastily but imperfectly cleaned instrument might convey fresh infection from one diseased ear to another. The probe in this case would be like the bee passing from flower to flower, while its limbs coming accidentally into contact with pollen of one flower, conveys it to and deposits

it upon others. The probe and the bee's limbs are accidental fertilising agents; but while the latter is a beneficent provision for the fertilisation and the possible evolution of varieties in plant form, the action of the former, whatever happiness it may afford the coecæ, is apt to destroy the host in which they flourish.

AUTO INOCULATION.

Besides these sources of infection one can reinfect the tissues of the middle ear by performing in the midst of swarms of pyogenic organisms operations involving a breach of surface in the layer of protective granulations, and thus expose fresh surfaces to the action of pyogenic cocci. Serious intracranial invasion has followed such septic operations. I hope, Sir, I have demonstrated that one who treats ear disease can no longer be looked upon as one whose whole duty is confined to the function of hearing. He has to act upon that small area of the temporal bone so as to prevent destruction of the whole organism. Every earist therefore must be a bacteriologist, and his operations are each of them, whether he wills it or no, bacteriological experiments.

I will conclude with the following propositions: (a) Infectious diseases extending to the brain and its membranes, or to the organs of the body from the middle ear and its annexes, are preventable. (b) When once these diseases are established in the middle ear, it is necessary to adopt means which will ensure their thorough eradication, and this must be regarded as a prophylactic measure against cerebral invasion. (c) When these diseases have once penetrated into the brain, not only does one require to remove the focus in the brain and that in the ear, but likewise the path between the two, by which infection has travelled.

Dr. Luc (Paris) said: I think the relation of the following case which recently came under my care is likely to prove interesting after Dr. Macewen's communication, as it confirms many of the views expressed in his excellent book with regard to the mode of infection of the cerebellum in the course of chronic suppurations of the ear, and to the possibility of recognising the formation of pus in the cerebellar substance, and treating it surgically. The patient, a mechanic, about 30 years of age, came to consult me at the end of last April, complaining of a scanty discharge from the right ear, and of a dull pain which he localised in the right half of the skull, and especially in the occipital region. The external meatus was so narrow that an otoscopic examination could not possibly give the slightest hint with regard to the condition of the tympanic membrane and of the ossicles, but making use of a Hartmann's cannula, which was pushed deeply through the canal and directed upwards and backwards, I succeeded, by injecting a boric solution through it, in expelling numberless caseous and cholesteatomatous offensive fragments. This induced me to suspect the presence of a considerable mass of the same substance impacted in the cavities of the middle ear, and I proceeded on the following day to the opening of the latter, following exactly Zaufal's method. I found the mastoid antrum transformed into a large cavity extending downwards to the insertion of the sterno-mastoid muscle, and backwards to the lateral sinus, which was exposed to the length of more than 1 centimetre. The ossicles and the oblique part of the upper wall of the auditory canal were completely destroyed. A bony projection of the superior wall of the antrum prevented me from seeing a large perforation of the tegmen, which an exploration by means of a fine probe had enabled me to suspect before the operation. My opening into the bone was a very large one, as you can easily judge from the petrous bone presented to you. I further dissected two cutaneous flaps, which were applied to the edge of the opening in the bone, with a view of creating a permanent fistula behind the ear. As I had detected no extradural abscess, and as the symptoms presented by the patient were not such as to suggest the presence of any intracranial complication, I considered my operation a sufficient one. The wound was dressed with iodoform gauze, and as there was neither fever nor headache, the dressing was only renewed after a lapse of a week. The patient then declared himself ready to resume his work. He came two days later in order to have his dressing changed, but after the lapse of two

days, I heard he was complaining of giddiness and vomiting, and could hardly stand. I found him without fever but still suffering from the above-mentioned symptoms, there being only slight headache. I referred his vertigo and vomiting to an auricular origin, having previously had several opportunities of observing similar symptoms after aural operations. He was admitted into hospital, and two days later, on May 16th, I found him without fever, and with a marked relief of his painful symptoms. I had every hope of a satisfactory result, but four days later, on May 20th, I was informed by my colleague that the patient had died on the night of the 18th. On the morning of the same day he had complained of a severe pain in the right occipital region, and had died after a very short coma without presenting the least thermic elevation. Before making the *post-mortem* examination I stated that, in view of the conditions observed during the operation on the mastoid, the patient had most probably died from an abscess in the right cerebellar region. The necropsy gave the following results: (1) A large perforation of the tegmen tympani; (2) a large perforation of the posterior wall of the antrum in front and internal to the lateral sinus; (3) no thrombosis of the lateral sinus, no extradural abscess; (4) no lesions of the temporo-sphenoidal lobe; (5) right hemisphere of the cerebellum occupied in its anterior third by a very fetid abscess, the middle third filled with green offensive pus, and only apparently normal in its posterior third. Although the presence of a double bony perforation in the case, the one on the tegmen pointing to an abscess in the temporo-sphenoidal lobe, the other close to the lateral sinus, suggesting a cerebellar abscess, might render a diagnosis for a moment doubtful, every symptom noted pointed so unmistakably to the latter, that had I been called in time to express an opinion with regard to a surgical intervention, I should not have hesitated to state my conviction that an abscess existed in the cerebellum. I am indebted to Dr. Bodin for the following bacteriological examination of the pus collected from the cerebellar abscess forty-eight hours after death. First, the microscopic examination showed a few chains of streptococci, cocci, and ordinary bacteria. Secondly, the bacteriological examination by means of cultures gave the following results: (a) Colonies of typical pneumococci (Talamon-Frankel) in great number; (b) a few scanty colonies of streptococci; (c) numerous colonies of ordinary bacteria of putrefaction.

Mr. MARMADUKE SHEILD referred to the protective influence of granulations, and the danger of lacerating them whilst the middle ear was swarming with organisms. Sir William Savory had pointed out the protective influence of healthy granulation against pyæmia. He (Mr. Sheild) questioned the statement that all these cases were tuberculous, and asked Professor Macewen what test he would regard as a proof of tubercle. So far as his own experience of extensive operations of the mastoid were concerned, they were disappointing in bringing about a perfect cure, although the patients were greatly improved. It was a general principle in surgery that in operations upon carious bone, if a small focus of disease was left, suppurative processes were perpetuated; and in disease of the middle ear, caries was apt to occur about the base of the petrous bone, which was not removable, as well as in the mastoid. He concluded by asking Professor Macewen as to his treatment of the general purulent meningitis, in association with middle-ear disease: such cases were peculiarly fatal, and he (Mr. Sheild) had hitherto been very unsuccessful in dealing with them.

Dr. MILLIGAN (Manchester) remarked that he had derived very great pleasure and profit from the paper which had just been read by Professor Macewen. With regard to the question of the value of the tuning fork as a means of differential diagnosis between cerebral and cerebellar abscess, he had not found it of any particular value. In a case of cerebellar abscess which he had recently seen, bone conduction was found to be remarkably good. He considered that tuberculous disease of the middle ear was a much more frequent condition than was usually supposed to be the case. He could not say that he had found any one symptom which might be regarded as pathognomonic of tuberculous middle-ear disease. He looked upon the painless asthenic onset of a purulent discharge from the middle ear, especially when accom-

panied by early involvement of the auricular glands and of facial paralysis, as highly suggestive of a tuberculous disease. In such cases he advised the employment of subcutaneous inoculation experiments as the only means of discovering the real nature of the process. He advised also very free removal of the bone and thorough packing of the cavity with pure iodoform powder. The utmost care should be taken to eradicate all tuberculous foci, as cases by no means infrequently occur where general tuberculosis is set up as the result of the presence of a tuberculous mastoiditis. In the treatment of all suppurative conditions of the middle ear, especially where granulations exist, he advocated the most rigid antiseptic treatment. Before the removal of granulations he specially insisted upon a preliminary course of treatment with antiseptics. He looked forward to the time when intracranial complications would become less frequent in consequence of earlier and more scientific treatment of purulent processes within the middle ear.

Dr. P. McBRIDE (Edinburgh) begged to join in the general chorus of appreciation which had greeted Professor Macewen's valuable contribution. With regard to the value of the tuning-fork test he was not aware of any very dogmatic statements on the matter in literature. In a paper published some years ago by the speaker, in conjunction with Mr. Miller, the suggestion was thrown out, but in the original work it was not insisted upon as by any means pathognomonic, although by some authors the paper has been quoted in this sense. If it be really so dangerous to wound granulations, the logical outcome would be that the aurist ought to give up the common and beneficial operation of removing the so-called aural polypus. Are we to give up this operation which, through many years, has proved itself both useful and beneficial? If the speaker understood Professor Macewen correctly, and if he had not misinterpreted his great work, he advocated operating upon all obstinate cases of middle-ear suppuration through the mastoid. Dr. McBride's own experience with regard both to cases in which he himself had operated, and those which he had seen treated by surgeons, might be shortly stated as follows: (1) In recent cases a rapid and permanent cure often results. (2) In old-standing cases, although an absolute cure occasionally results, more frequently only more or less temporary benefit ensues. The discharge may be reduced to a minimum or even disappear for a time, but very often it gradually returns; therefore Dr. McBride believed that one was not justified at present in holding out definite hopes of cure in this class of cases, and therefore he hesitated to recommend operative interference unless symptoms other than discharge are present as well.

Professor URBAN PRITCHARD said that at a meeting of the British Medical Association at Leeds, Professor Macewen gave otologists a kindly scolding for not more emphatically insisting on all patients with otorrhœa being thoroughly treated. He had transferred this scolding from himself to his patients with very good results; that is to say, on first seeing such a patient he gave him a good-tempered scolding; this made him carry out the directions much more faithfully, and hence with better results. Following up the remarks on antiseptics, Dr. Pritchard said he wanted to insist upon the dangerous practice of syringing with plain warm water in otorrhœa. In removing granulations from the middle ear, he always syringed previously with carbolic solution, 1 in 40, then removed antiseptically, and finally treated by again syringing with 1 in 40, and packing with double cyanide gauze. The gauze is changed once a day for four or five days, without syringing. This yielded excellent results, and reduced the danger of the infection of the deeper parts to a minimum. In cases of operating for intracranial disease, he (Dr. Pritchard) would like to express his opinion that the antrum and mastoid process should never be neglected; in fact, he considered we should begin by opening these cavities first.

Dr. DUNDAS GRANT, as a careful student of Professor Macewen's classical work, had endeavoured to make use of the burr but had failed to make any impression with the instrument at his disposal, and had been obliged to resort to gouge and mallet. He determined to procure such burrs as Professor Macewen recommended. The description of Dr. Luc's case was identical with that of one under Dr. Grant's care. The

symptoms suggested an intracranial abscess and the situation of the carious disease pointed to the temporo-sphenoidal lobe as the probable site. The mastoid was then opened, the carious opening in the tegmen enlarged outwards, and some extradural pus removed. Exploration of the temporo-sphenoidal lobe revealed no pus but a large quantity of ventricular fluid escaped and the patient became much less drowsy. Next day he seemed so much better that operation on the cerebellum was considered uncalled for. A few hours later Dr. Grant again visited him with a view to the consideration of the necessity for operation, but was met with the report that the patient had a few minutes before been attacked with difficulty in breathing and had suddenly died. On *post-mortem* examination there was found an abscess in the corresponding lobe of the cerebellum in contact with a minute carious perforation in the posterior surface of the petrous bone, internal to the sigmoid sinus, whereas the very large carious aperture in the tegmen communicated with no disease of the temporo-sphenoidal lobe. He therefore insisted on the danger of delay in operating on suspected cerebellar abscess, and quoted the experience of neurologists that death in cases of cerebellar disease of any kind was very frequently sudden. In cases of chronic suppuration—apart from severe attacks of pain—even when not yielding to other methods of treatment, extraordinarily favourable effects were obtained by an energetic use of the alcohol treatment, a method combining bactericidal and dehydrating effects.

Mr. ROBERT H. WOODS (Dublin) thought an aurist should not merely content himself with the examination and medical treatment of ear diseases, but should be capable of carrying out surgical procedures where indicated, even to the extent of treating intracranial complications. He then showed specimens from two patients on whom he had operated for intracranial abscess. The first case, one of cerebellar abscess, occurred in a girl aged 20, who while suffering from chronic purulent otitis media developed symptoms of right lateral sinus thrombosis. The mastoid process was opened, the middle ear cleared out, the thrombosed lateral sinus laid bare, and a cerebellar abscess evacuated. The internal jugular vein was ligatured in the neck, and the clot removed. She rallied for some days, but finally died of asthenia twelve days after operation. The second specimen was taken from a man aged 33, who had been sent into hospital as a case of fever, and who had symptoms of extradural abscess. He was operated on, and a large extra- and intradural abscess in the middle cranial fossa evacuated, the dura mater having been eroded to the size of a florin. A temporo-sphenoidal abscess was also opened and drained. He never rallied, and died seven days after operation, when it was found that in addition to the conditions diagnosed during life he had diffuse purulent leptomeningitis, and that the ventricles were filled with pus.

Dr. THOMAS BARR (Glasgow) referred to the importance of the middle ear as a source of tubercle, which he pointed out for the first time at the Otological Congress in London, 1881. The subsequent history of events has confirmed the opinion expressed at that time. In regard to granulation tissue and polypi, Dr. Barr had been in the habit of using antiseptic remedies before the instrumental treatment of the growth. This is a precaution of great importance, and likely to avert serious intracranial complications, which have probably at times followed their removal. The treatment of purulent disease of the middle ear by operation on the mastoid, which has resisted all other methods, had been found, in his experience, very satisfactory. Of eight cases operated on, six proved perfectly successful, and the other two showed only the slightest trace of secretion. The use of the dental burr is of the greatest value in securing success, but it is essential that the burr should be good.

Mr. JAMES BLACK referred to the use of alcoholic instillation as a subsequent treatment to the removal of granulations, and as a means of attaining a partial asepsis.

Mr. BALLANCE pointed out the importance of an early diagnosis of tubercle in aural disease, and the necessity of keeping up thorough and prolonged drainage through the mastoid.

Dr. ROBERTSON agreed as to the great importance of free drainage and asepsis. He advocated the use of a lead stylet to be worn constantly in the mastoid wound; he had also

found the dry treatment, with or without iodoform, more satisfactory than syringing with antiseptic lotions, provided all the necrotic tissue had been removed.

The PRESIDENT (Sir William Dalrymple) drew attention to the great value of clinical observation in separating cases of general meningitis from cerebral abscess. The defensive operation of opening the mastoid cells, making a free drainage through the tympanic cavity, and removing whatever bone was carious should be employed under the several conditions which were discussed. These included imperfect exit for pus from tympanic cavity due to bone granulation, polypus, exostosis, or hyperostosis. Especially if there were head pain or giddiness this surgical proceeding became imperative.

Professor MACLEWEN, in reply to some of the points raised during the discussion, said that the symptoms of cerebellar abscess would depend upon the level of the pressure. It was the duty of the surgeon to operate even if the case were apparently hopeless, as he himself had seen some cases recover which had appeared very unfavourable. It was useless to attempt to eradicate tubercle by means of the syringe; if the disease was confined to the middle ear and mastoid the case could be cured by operating, but if the internal ear or the petrous portion of the bone were affected, it would be impossible to cure it. It must be recognised that suppuration would continue; it was therefore important to keep open the surface drainage. He considered that there was a certain amount of danger in syringing out cavities; he preferred if possible to keep them dry. Disease of the middle ear should be treated on ordinary surgical lines, all foci being carefully removed, and care being taken to have perfect antisepsis. He believed that the burr was much more effectual than the mallet and chisel for mastoid operation.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

UNIFORM INCOMPLETE INFLATION OF BOTH LUNGS.

On October 17th I was called upon by the coroner for this district to make a *post-mortem* examination of the body of a child, aged 3 days, who had died suddenly. The body proved to be that of a female child, plump, and weighing, I should think, about 10 lbs. The face was decidedly cyanosed, the body not markedly so. The umbilical cord was dried up, but had not begun to separate.

On opening the head I found the larger veins of the meninges engorged with blood, but there was no network of small vessels and capillaries as seen in congestion. The brain and appendages were otherwise normal.

On opening the chest it was seen that the lungs were not fully inflated, the edges only being in view, and the anterior portion of the chest cavity between the vertical nipple lines was occupied by the thymus gland and pericardium only. The lungs were dark red in colour throughout, and very much like liver in consistence and appearance. No crepitation could be elicited anywhere. They were, I should judge, of about one-third the natural bulk, and very nearly of the same specific gravity as water, barely floating; all portions of the lungs behaved in the same way. Both main bronchi contained much frothy mucus. The respiratory passages were otherwise normal.

The greater veins on the surface of the heart were engorged and prominent like the meningeal veins. There were no sub-pericardial petechiae. The right side of the heart was full of abnormally fluid blood. The ductus arteriosus was patent and not greatly diminished, and the foramen ovale was almost closed. The valves were in their normal condition, and the heart seemed otherwise healthy. The stomach was distended with mucus, evidently from the respiratory passages, in which a few small white flakes of what might have been milk were seen. The mucous membrane was normal, as were the rest of the viscera.

According to the evidence the child was seen alive with its mother at 10.45 A.M.; at 11 A.M. a neighbour came to see the mother, and chatted with her for twenty minutes, then

looked at the child, and found it lying dead, face downwards, and covered with the bedclothes. The mother was an epileptic, and the neighbour thought that she had had a fit during the time she was left alone.

I gave it as my opinion that, owing to the abnormal condition of the child's lungs, a very short duration of suffocation would be sufficient to kill it, and that death was probably due to its being lain upon or rolling on to its face. The jury returned a verdict of accidental death.

Everyone connected with the child declared that it was most healthy in every way, that it cried lustily, and suckled freely.

I venture to report this case as I deem it not to be without some medico-legal interest.

Rugeley, Staffs.

RICHARD FREEER, M.A., M.B. Cantab.

TWO CONSECUTIVE ATTACKS OF SCARLET FEVER.
A. T. S., a boy, aged 5 years, was taken ill on May 13th last, and when seen, the day following, presented all the symptoms of scarlet fever. The rash was well marked, the temperature high, and the tonsils swollen and injected. It ran a moderately severe course, and desquamation began about the ninth to the tenth day, and continued till the eighth week.

At the tenth week, having apparently quite recovered—no kidney trouble having supervened, the urine being free from albumen throughout—the patient was allowed out for a short time, and whilst out was overtaken in a shower of rain, and probably took a chill, as he complained the same night of his throat and vomited twice during the night. Next morning both tonsils were found to be much enlarged and congested; the temperature was 104°, and again a punctate scarlet rash appeared on the chest and back, and rapidly spread over the whole body. It was deep red in colour as before and of the boiled lobster type. With this second attack bronchial catarrh and a certain amount of bronchial congestion was present, due, no doubt, to the boy's exposure to the weather. Altogether this second attack was of a more severe character. Desquamation, which was as well marked as before, commenced about the end of the first week and lasted till about the end of the eighth week, that is, to the middle of September, eighteen weeks from the commencement of the first attack.

The case appears to me to be of interest from the somewhat rare occurrence of second attacks of scarlet fever, and in the fact that the rash in the second attack was both present and well marked, and desquamation as perfect and characteristic as in the attack which immediately preceded it. In corroboration of both attacks being genuine scarlatina I may mention that in addition to the other well-marked symptoms present the rash, which lasted three days and no longer, was in each case followed by desquamation of the ordinary furfuraceous kind on the body and the usual large flakes from the extremities.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

JONATHAN HURST, B.A., F.R.S., President, in the Chair.

Tuesday, November 12th, 1895.

ADJOURNED DEBATE ON DR. HEWITT'S AND MR. SHEILD'S PAPER ON POSTURE IN ITS RELATION TO SURGICAL OPERATIONS UNDER ANÆSTHESIA.

DR. SCANES SPIGHER was specially interested in anæsthetics in connection with operations on the throat and nose; in no class of cases was posture of more importance. In his experience local anæsthesia induced by cocaine was more satisfactory than general anæsthesia, and in throat operations generally the sitting posture was, since it gave a better view, far more useful than the recumbent. The authors stated that nitrous oxide and ether were not dangerous in the sitting posture; he would be glad of further information on this point. Was any special precaution necessary to keep the air passages properly open in the sitting posture? Was there any special way in which the tongue should be manipulated, and how long should anæsthesia be kept up? In

children he had never seen bad results from the administration of chloroform for the space of half an hour in the sitting posture. In laryngeal operations he had found Trendelenburg's posture very satisfactory.

DR. SANSON complimented the authors on their paper, and said that, according to them, though nitrous oxide and ether were permissible, chloroform should never be given in the sitting posture, nor, unless under special circumstances, in the semi-recumbent posture. He did not understand this unless failure of the circulation was feared. He inferred from the context that the authors endorsed the very important observations of Dr. Leonard Hill on the Influence of the Force of Gravity on the Circulation of the Blood.¹ Dr. Hill concluded that chloroform paralysed the splanchnic vasoconstrictors, and thus annulled the compensatory vasomotor mechanism in regard to the intra-abdominal vessels. A direct poisoning of the cardiac muscle might be a concurring cause. Dr. Hill's observations were in complete accord with those of Dr. MacWilliam, and were at variance with the conclusions of the Hyderabad Chloroform Commission. Syncope was a very real danger attending the administration of chloroform. Ever since the introduction of chloroform there had been two modes of thought and two schools of practice. Syme taught that chloroform might be administered with perfect safety provided the administrator observed the respiration of the patient with sufficient care. Lister followed, endorsing this teaching. The Hyderabad Commission confirmed the doctrine, adding that if its rules were followed "chloroform might be given in any case requiring an operation with perfect ease and absolute safety so as to do good without the risk of evil." The doctrine throughout was that precautions as to the proportion of chloroform in the air administered were unnecessary; and that the danger of syncope did not exist; but it was right to state that the Hyderabad Commission insisted that the recumbent position on the back was essential. On the other hand, in the early days of chloroform administration and thenceforward, many observers had held different views. Snow, Anstie, Clover, and Richardson in the past and a number of practical anæsthetists of the present day held that chloroform in itself was an agent which could induce syncope, and that not only must postural and other methods be adopted to avoid the tendency to syncope, but precautions must be taken against the inspiration of a harmful percentage of chloroform vapour during the administration. Physiologists, as MacWilliam, McKendrick, Coats, Newman, and now Leonard Hill, had shown that experimental evidence was in favour of this view. Up to the end of October, 1885, there had been recorded in the medical journals 48 deaths during the administration of anæsthetics—41 in which the agent was chloroform, 3 chloroform and ether, 1 A.C.E. mixture, and 1 nitrous oxide. Of these, 39 deaths occurred before the operation was commenced; 2 just at the commencement, and 7 directly after. Was the teaching of this evidence satisfactory? The rules of the Hyderabad Commission had been widely circulated; it was only reasonable to conclude that the respiration in the cases had been closely watched, and yet a very high mortality was the commentary. In his book on chloroform, published thirty years ago, he had recorded the results of a considerable number of experiments upon animals, which tended to show that in the great majority of instances when death resulted from chloroform administration it was the respiration that ceased first. This had been confirmed by the Hyderabad Commission, and by all subsequent observers. He concluded, however, from practical observations and from an analysis of the signs in fatal cases that in the human subject the most frequent form of death was that from syncope. Notwithstanding all the valuable experimental evidence, he held this view still. He hoped he would not be misunderstood, and be represented as decrying the value of experimental evidence as obtained from the lower animals. The experiments of the Anæsthetic Committees, the Hyderabad Commission, and the private investigators, were of extreme value, as in a question of this sort it was important to obtain by all legitimate means precise data as to the *modus operandi* of anæsthetics.

¹ *Journal of Physiology*, vol. xviii, 1895.

upon the lower animals. But the heart and circulation reflexes of man were not in all points as the heart and circulation reflexes of an animal. He did not think that in the fatal cases in man any morbid state of the heart itself had been an appreciably dangerous pre-disposition. A strong muscular heart was as likely to fail as a weak one, and perhaps the strong was more likely to fail than the weak. Of course the heart should be examined before the administration of an anæsthetic, but he was not aware of any evidence in regard to disease of the valvular apparatus or of the myocardium that would absolutely exclude anæsthesia. Yet the nervous mechanism of the heart might be fatally troubled quite independently of the other physical structures. He had seen a soldier of undoubted courage, who had been in many battles, and who gave evidence of healthy organs, fall in syncope when he was vaccinated; and had recorded cases of typical athletes, who manifested no physical signs whatever of disease of the heart, and yet fell down on several occasions in syncope. He had noted several such examples after convalescence from the acute stage of influenza. All such cases of instability of the nervous mechanism, undetectable by ordinary physical explanation, were probably the most pre-disposed to chloroform accidents. Dr. Hill said: "The symptoms of syncope were exactly similar to those conditions observed in an animal placed feet downwards with the power of compensation destroyed by the production of vasomotor paralysis." Syncope was very probably the result of a sudden and temporary inhibition of the vasomotor centres, especially those governing the splanchnic area. These considerations pointed to the importance not only of placing the patient on the back with the feet elevated above the head level in cases of ordinary syncope, but also of preserving, when possible, such an attitude during the administration of an anæsthetic, or at once adopting it if there should be signs of circulatory failure. From a review of all the extant evidence, the conclusion was justified that syncope was a very real danger in the course of anæsthesia by chloroform, that such syncope, brought about chiefly by a paralysis of the vasomotor mechanism, though, possibly, by a direct enfeeblement of the ventricles as a concurring cause, was shown to occur in the lower animals, and that in the human subject circulatory failure was predisposed to by emotional and neurotic conditions, which did not occur, or occurred in far less degree, in the lower animals. He considered the postural precautions advised by the authors important, not only for practice but for precept, as they tended to antagonise the, to his mind, pernicious doctrine, that there was no danger in the administration of chloroform beyond the preventable danger of embarrassment of respiration.

Mr. W. SPENCER WATSON always used local anæsthetics in throat cases. Chloroform he thought should not be employed. He described a convenient arrangement for keeping patients recumbent before, after, and during operation, which was in use at the Royal Eye Hospital, and which he thought might be adopted for cases with advantage.

Mr. WOODHOUSE BRAINE joined issue with the authors on their statement that it was better for the patient to be anæsthetised on the operating table. He was in favour of inducing narcosis in bed, and then moving the patient on to the table. He did not agree that this plan was more troublesome or likely to provoke sickness; as long as the anæsthetic was carefully looked after there was no likelihood of vomiting. He did not agree with the authors' suggestion as to the arrangement of Clover's crutch. The sitting posture for the removal of adenoids was originally proposed by Sir W. Dalrymple in 1883, and had been followed with uniform success in many hundreds of cases without any coughing or entrance of blood, etc., into the larynx. He agreed thoroughly with the authors as to the advantages of turning the patient on to one side after the operation, and had himself done so for ten years past.

Sir W. DALRYMPLE complimented the authors on the careful and valuable paper they had produced, and ventured to suggest that they should omit some directions about the use of sponging in two of the postures mentioned, since he considered these two postures dangerous, and the authors' implication that with careful sponging the postures might be employed was, he thought, undesirable.

Dr. SAMON thought the discussion had very naturally turned

on the production of anæsthesia in throat and nose cases, since it was especially in these operations that respiration became embarrassed. He drew attention to the postures employed in operations on goitre. In hard goitre especially, absorption of the rings of the trachea often occurred; if the head was rotated laterally the trachea being flexible became occluded, and death from suffocation before the operation had been begun had occurred in some cases. He quite agreed with the authors in recommending that anæsthesia should be induced in the position which the patient felt instinctively to be most comfortable, and which was so as giving the best entry of air. In this manner the tendency to reflex spasm was avoided. With regard to adenoids he thought it important not to carry anæsthesia so far as to abolish the laryngeal reflex.

Dr. LEONARD HILL, speaking as a physiologist, would not go so far as to recommend elevation or compression of the abdomen in chloroform shock. The primary cause of chloroform shock was dilatation of the heart—cardiac failure. Respiration continued after the heart had failed; this he had termed "post-mortem respiration." Elevation of or pressure on the abdomen would only make matters worse by farther dilating the heart. The only thing to be done was rhythmical compression of the heart, so as to drive blood into the coronary arteries. Failure of the respiration was not serious as long as the heart was acting satisfactorily. Cardiac failure did not occur in ether narcosis. As in man, so in animals, the condition of tone of the vasomotor system varied considerably. Dr. Hill described the changes in the general circulation brought about by variations in the condition of the splanchnic vasomotor system, and drew attention to the fact that mere mechanical pressure on the abdomen raised the blood pressure, and so was useful in cases of ordinary shock, but was not of the slightest good in collapse from chloroform narcosis when the heart was primarily at fault.

Dr. R. BOWLES, in experiments conducted forty years ago at St. George's Hospital, had noticed that when the body was in the prone position, raising the chest gave rise to expiration and not to inspiration. With regard to posture, he did not wish to dogmatise. Numerous physical conditions, such as obesity, length of jaw, etc., modified the conditions of respiration. Pulling on the tip of the tongue did not necessarily affect the position of the back of the tongue, as was often thought. Turning to failure of the heart in chloroform narcosis, was not the explanation that the heart was poisoned by an overdose of chloroform? It would be well to measure accurately the amount of chloroform given, with the view of avoiding this catastrophe. Apoplexy had been thought to be of two kinds—sthenic and asthenic, but he had long been convinced, and had shown, that so-called sthenic apoplexy was only incipient suffocation, and that its symptoms—among which stertor was the chief—all disappeared on turning the patient on his side. He had always maintained that in the Marshall-Hall method the heart was squeezed and the blood forced on.

Mr. G. ROWELL quite agreed with the authors' useful generalisations. He drew attention to the influence gravity exerted in the falling of the base of the tongue backwards when the head was in the mid-dorsal posture. Cyanosis, though more marked in ether narcosis, was of less importance than in chloroform anæsthesia. The extended position of the head in tracheotomy was dangerous, and death not uncommonly occurred before the operation was begun. Two cases were quoted illustrating the danger of cardiac failure in the sitting posture. He was of opinion that the best practical guide was the respiration, and in support of this quoted the successful results of Surgeon-General Lawson. Dr. L. Hill's plan of rhythmical compression of the heart was in accordance with his own views, as expressed in the *Guy's Hospital Reports* (Accidents of Anæsthesia), 1892.

Dr. J. F. SILE said the title and the arrangement of the paper under discussion reminded him of one read by the late Dr. C. E. Sheppard on January 8th, 1891, at a meeting of the anæsthetists of Guy's Hospital. This paper had not been published, and though it was possible that it was based on extensive notes, he had not been able to make out that they were in existence. To a certain extent, also, the subject of the paper had been discussed in general works. It was important to distinguish between postures adapted for inducing

and those for maintaining anaesthesia; postures suitable for one were by no means necessarily satisfactory for the other. The difficulty in swallowing in dental cases, when the head was extended, was due rather to the mouth being forcibly kept open than to the extension of the head and neck. He could not agree with the suggestion that in shock from chloroform the abdomen should be bandaged, and was glad that Dr. Hill's physiological results were in accord with his views on this point. He inquired what posture the authors thought best adapted for cerebral operations, for in such cases gravity played an important part in influencing the circulation in the cerebral veins. As to turning the patient on one side after the operation he agreed with the authors, but thought the right side was better than the left. While the authors recommended the lateral posture as being the best for the induction of anaesthesia, he thought the recumbent was better.

Dr. F. HEWITT, in reply, said that Mr. R. Gill had stated that he did not attach much importance to posture. The opinion was at variance with that of most observers, and possibly phenomena ascribed to other causes were due to faulty posture. Mr. Gill's experience in not having seen deaths due to vomited matters entering the larynx was exceptional. In reply to Dr. Spicer, the time during which a patient could be kept under depended on the amount of ether required. Mr. Woodhouse Braine's remarks were valuable in bringing up for reconsideration the question whether the patient should be anaesthetised on the table or on the bed. The stoppage of respiration which sometimes occurred in gaitre cases when the head was extended (not rotated) was as yet unexplained. He was sorry Dr. Silk had found it necessary to refer to the late Dr. C. E. Sheppard. The notes of 3,000 cases recorded by his late friend had been carefully gone over and referred to in his (the speaker's) book. At Dr. Hewitt's request, the Honorary Secretary (Dr. Mitchell Bruce) then read a letter from Dr. W. J. Sheppard, of Putney, saying that he had no knowledge of any paper on the subject of posture in relation to anaesthetics among his late brother's effects, except that published in the *BRITISH MEDICAL JOURNAL*, 1891, vol. ii, p. 68, and that he had recently searched without finding any.

CLINICAL SOCIETY OF LONDON.

THOMAS BUZZARD, M.D., F.R.C.P., President, in the Chair.

Friday, November 8th, 1895.

SUPRAPUBIC PROSTATECTOMY.

MR. MANSELL MOULIN read notes of two cases, both in men over 60 years of age and heavily built. One had already passed five uric acid calculi spontaneously, the other three. In the former, when the bladder was opened above the pubes, eighteen more calculi were found lying in the post-prostatic pouch, all of them approximately of the same size and shape, and ground into a more or less cubical shape by friction. Each was a distinct calculus with a nucleus of uric acid. In the latter there was only one about the size of a penny, but a good deal thicker, and fitting accurately in the pouch. In each case there was considerable median upgrowth of the prostate into the bladder behind the orifice. This was excised with scissors and cutting forceps, a mass as large as a walnut being removed, and the route made level and as smooth as possible. No constitutional disturbance followed in either case. The wounds healed rapidly without leaving a fistula, and urine was passed by the urethra in about three weeks. Convalescence was a little delayed in one of them by an attack of epididymitis that followed the introduction of a catheter. Union was greatly helped by means of a truss, shaped something like a double inguinal truss, devised by Dr. Birch, of Clapton, so arranged as to press the deep surfaces of the wound together. The cases were brought forward as illustrating a principle suggested by Mr. Mayo Robson, that in cases of multiple or recurrent calculi, associated with median vesical enlargement of the prostate, the best operation was suprapubic cystotomy with excision of the intra-vesical portion of the upgrowth so as to obliterate the post-prostatic pouch. Lithotomy or lithotripsy, without this addition, was in such cases little better than a temporary expedient. The removal of the projecting portion of the

prostate did not add materially to the gravity of the operation so long as the urine was acid. The high rate of mortality with which suprapubic prostatectomy was credited was due to the fact that it had nearly always been performed as a last resource in hopeless cases where everything else had failed, where the patient's strength was completely broken, and where the wall of the bladder was infiltrated with septic organisms from long-continued suppurative cystitis. In cases in which the urine was acid and was kept aseptic the prognosis was entirely different.

MR. GOLDING-BIRD thought that even in old persons it was safer to employ the suprapubic method to clear the bladder, whether any prostatic growth were removed or not. He thought the risk less than when perineal lithotomy was performed.

MR. BUCKSTON BROWNE considered that excision of the median lobe of the prostate added much to the risk. He thought the author's second case might have been advantageously dealt with by lithotomy.

MR. MANSELL MOULIN, in reply, thought the gravity of the excision depended on the amount of prostate removed. Ablation of the middle lobe, if the urine remained acid, added little to the gravity of the operation, and, as a result, after-coming calculi would be easily expelled *per vias naturales*.

INTUSSUSCEPTION THROUGH A PATENT MECKEL'S DIVERTICULUM.

MR. GOLDING-BIRD reported a case of intussusception with Meckel's diverticulum at the navel. The patient was an infant, 4 weeks old, through whose navel soon after birth a red protrusion was seen, through which motion passed shortly before coming under observation. The protrusion had increased and altered in character. Its appearance in all respects corresponded with that of an intussusception, and this diagnosis was given, it being further regarded as one of protrusion of the distal, and not proximal, bowel through the open navel. It was not possible to undertake any operation, and the child shortly died. The necropsy showed the diagnosis to have been correct. The author remarked on the rarity of these cases, and referred to a paper by Barth, which dealt exhaustively with them. That surgeon quoted a very similar case to the one now brought forward, but the intussusception was from the proximal into the distal gut (Meckel's diverticulum), and not in the reverse direction. Mr. Golding-Bird considered his case as, in all probability, unique, and pointed out that the chance of recovery could only be given by a laparotomy with (probably) resection of the affected gut, but his patient was too collapsed to permit of so grave an operation. All the cases of complicated prolapsed and patent Meckel's diverticulum that he had been able to discover had ended fatally, and therefore considerable immediate risk to life by operation was certainly warranted.

THE PRESIDENT pointed out that in ordinary intussusception the proximal portion of the bowel was usually invaginated into the distal part, but in the author's case the reverse was the case.

MR. HOWARD MARSH inquired if it would have been possible, *post mortem*, to reduce the intussusception, the Meckel's diverticulum being short.

MR. GOLDING-BIRD, replying, said that during the patient's life he considered that nothing less than resection of the bowel would have proved of use, so hard and unyielding was the part. The patient was not at the time fit to undergo laparotomy, but he had hoped to do so later on. At the necropsy reduction of the intussusception was found to be impossible.

OSTEOPATHYOSIS (FRAGILITAS OSSUM) IN WHICH AFTER UNION HAD TAKEN PLACE DISUNION OCCURRED AFTER THE LAPSE OF SEVERAL YEARS.

MR. LANGTON read notes of this case. The patient, aged 23, when first seen in 1883, had been the subject of several so-called "spontaneous fractures" as the result of muscular action or of very slight injury. In all except one firm union had ensued, but in one fracture of the femur, after unnecessary violence on the part of a bonesetter, the fracture never became firmly united. Subsequently two united fractures of the left femur and the right humerus became firm, then disunited, and the latter eventually became the seat of a sarcomatous growth.

Mr. EDGAR WILLIAMS had been particularly struck by one specimen, that of the humerus. It looked as if fractured at the upper end, but there was in reality no bone at all between the cartilage at the upper and lower extremities. He remembered a child who had broken six of his long bones, only one of which, the clavicle, showed any signs of callus. Since then the child had been in good health.

Mr. LUNN had seen several of these cases in patients suffering from locomotor ataxy. All of them had united. The existence of the fractures had been discovered accidentally by the nurses.

The PRESIDENT asked whether in Mr. Langton's case sarcoma was present when the patient had his first fracture at the age of 11. He (the speaker) had recently seen 3 cases of mollities ossium: one now under care, a woman, aged 34, had fractures of both femora, and since admission she had fractured a humerus by merely raising herself upon it. Both the other patients died, with sarcoma extensively distributed. His present patient had no sign of malignancy, her general health being very good. All the patients were single women.

Mr. L. BENHAM asked if the bones were rarefied in the author's cases. Cancer of the long bones caused softening just as did mollities ossium.

Mr. LANGTON, in reply, said that sarcoma of several bones was not common, nor was it common for such a growth to remain quiescent for twenty years. Further, the other bones were quite normal, and exhibited no sign of malignant infiltration. He asked if others had met with similar cases of disunion of bone after so many years of osseous union.

BRAIN TUMOUR SUCCESSFULLY TREATED BY INTERNAL MEDICATION.

Dr. ALTHAUS related the case of a lady, aged 39, in whom unmistakable symptoms of a tumour in the right central convolutions became developed in 1882. The chief signs were severe headache, cranial tenderness, and tympanitic sound on percussion, a change in her manner, drowsiness in the daytime, epileptiform convulsions, paresis of the left side of the body with increased tendon reflexes, optic neuritis, impaired memory and inability to think, and sickness and vomiting. The first symptoms had appeared after parturition, and there was a history of a severe blow on the head many years ago, but no syphilitic infection. Treatment by full doses of mercury and iodide of potassium caused rapid improvement, and total disappearance of the principal symptoms in six weeks. Several relapses happened in the course of the following years, at variable intervals, and these yielded to the same treatment as readily as the first attack. The last serious relapse occurred in 1888, and a very slight one, with few symptoms, in September, 1892. Since then the patient had remained quite well, and able to enjoy life. Dr. Althaus had in similar cases seen satisfactory results from similar treatment, but the latter had generally been more protracted than in the present instance. He thought the tumour might have been a glioma, but as it was, fortunately for the patient, never seen or handled, it was impossible to determine its nature. With regard to the diagnosis, he stated that there was no other disease which would produce the whole group of symptoms which had been present, while one and all of these could be easily accounted for by the presence of a growth in the affected portion of the brain. He concluded by remarking that a case like the one related, and in which such ominous symptoms as optic neuritis, epileptiform convulsions, and loss of mental power, were traced to their origin, and removed by acting upon the seat of the malady, not only tended to give us confidence in our power over disease, but also furnished a very clear reply to that therapeutic nihilism which was so frequently paraded by those who did not know how to use the remedies which were at our disposal.

Dr. WALSHAM inquired the cause of the tympanitic note over the affected region.

Mr. LUNN recalled several cases of tumour following fractures. In one instance, after fifteen intervening years of health, fracture of the base was followed by the development of glioma in the anterior part of the cerebrum. He also cited other similar instances. It was quite new to him, however, to find glioma yielding to medical treatment.

Dr. WILSON related a remarkable case of supposed cerebral tumour or of tuberculous deposit in a boy aged 12, who had

optic neuritis and exaggerated reflexes, and finally total inability to move the limbs. He grew worse on iodide and perchloride of mercury, and was then sent to the seaside, where, after four or five months, he improved, and at length made a complete recovery.

The PRESIDENT said the interest of the case was in the syphilitic or non-syphilitic nature of the lesion: if the latter the case was remarkable. Did the iodide and mercurial treatment influence non-syphilitic growths? He had diagnosed cerebral tumour from very palpable signs during life, and used the treatment as matter of routine to find much improvement in the patient's state. This, however, ceased, and the patients had died, with discovery, *post mortem*, of gliomata. On the other hand, when tumours were cured by this treatment, one was, perhaps, too apt to think they had been syphilitic. In the tongue hard tumours at first improved under large doses of the treatment, then the growth recurred and ran its course. Also with tumours of the oesophagus the same thing ensued.

Dr. ALTHAUS said that syphilis could be absolutely excluded in the case he had narrated. The lady had had four healthy children and no miscarriages. He had never seen any other case of brain tumour recovered from. He had seen the association of injuries with such growths.

MEDICAL SOCIETY OF LONDON.

Monday, November 11th, 1895.

Sir J. CRICHTON BROWNE, M.D., F.R.S., President, in the Chair.

CLINICAL EVENING.

ADDISON'S DISEASE TREATED BY SUPRARENAL EXTRACT.

Dr. SANSON showed a man, aged 25 years, who seven months ago began to feel weak on walking a short distance, and developed areas of pigmentation on the face, knees, etc. The pigmentation was not typically that of Addison's disease, but the patient suffered from intense headache and nausea, without vomiting. Under arsenic he had continued to lose weight, but when put on a treatment comprising the administration of one and then two tabloids of suprarenal gland three times daily, he improved wonderfully, gaining 14 lbs. in weight in a month. He was then sent to the seaside, the treatment being discontinued. He remained in fair health for a time, but latterly he had again begun to lose weight, and to suffer from his headache as before. Dr. Sanson proposed to reinstitute the suprarenal treatment, but admitted that it was quite possible the previous improvement was merely an arrest in the natural course of the malady. The urine had been found to contain occasional traces of albumen but never any sugar.

Dr. ALTHAUS recalled a typical case of what is known as "bronzed diabetes," in which he had tried the suprarenal treatment. A great improvement had at first resulted, but it was not maintained, and the patient died.

Dr. SAVILL urged that the distribution of the pigment did not suggest Addison's disease, and he pointed out that the mottling over the knees resembled that seen in those who roasted the knees before the fire.

TEMPORARY RESECTION OF THE UPPER JAW FOR NASOPHARYNGEAL GROWTH.

Mr. STANLEY BOYD showed a man, aged 49, who presented himself with a large naso-pharyngeal growth springing apparently from the base of the skull or front of the spine, completely blocking the right nostril, which bulged, and displacing the right eye. In order to obtain free access to the growth for the purpose of effectual removal, he exposed the superior maxilla, snipped through its points of attachment, and then, without difficulty, he tilted it out, thus obtaining free access to the growth, which invaded the sphenoid bone. As a precautionary measure he had exposed the right carotid artery before commencing the operation, in order to be enabled, should occasion arise, to control the hemorrhage. As a matter of fact the hemorrhage never caused any trouble, and no difficulty was experienced in replacing the jaw in position where it reunited. The resulting deformity was very small, and the lachrymal duct was not interfered with, and the patient made an excellent recovery.

Mr. MANSELL MOULLIN related a somewhat similar operation which he had performed with the same object in view. He did not deem it necessary to expose the carotid artery, but he performed a preliminary tracheotomy, which proved a wise course, because it enabled him to keep a sponge in the mouth to prevent "sagging" of the muco-periosteum of the hard palate.

Mr. WALSHAM advocated obtaining access to these growths by cutting through the soft palate and chiselling away sufficient of the hard palate, an operation which he had performed with complete success in more than one instance. He pointed out that this operation was vastly less severe than resection of the upper jaw: it left no scar and did not expose the patient to the risk of interfering with the lachrymal apparatus.

Mr. WALLIS endorsed the view of the last speaker, and related a case in which he had himself operated on those lines. The patient, however, was in an extremely weak condition, and succumbed a few hours later.

CONGENITAL FEEBLEMINDEDNESS WITH CONGENITAL DEFICIENCY OF CHEST WALL.

Mr. HAROLD showed a lad, aged 16, who presented congenital deficiency of the rib cartilages on the left side below the fifth rib, thus uncovering the precordial area. He was also congenitally feeble-minded. He was also the subject of extensive heart disease.

Dr. SANSON pointed out that the hypertrophy bore mainly on the right ventricle; and he suggested that there was probably patency of the foramen ovale or ductus arteriosus.

Dr. SHUTTLEWORTH agreed that the association was common.

WIRED FRACTURE OF PATELLA IN A MAN AGED 70.

Mr. WALLIS showed a man, aged 70, on whom he had successfully performed the operation of wiring a fractured patella. He had remarked in the course of the operation that the dipping down of the aponeurosis would have effectually prevented coaptation of the bony fragments by the ordinary methods. Mr. Wallis also showed a lad in whom suppuration of the knee joint had supervened consequently on disease of the tibia, who notwithstanding had preserved very good movement of the joint.

SPINA BIFIDA OCCULTA.

Dr. GUTHRIE showed a child with spina bifida occulta, who six months ago had developed paresis of the left leg, which he attributed to degenerative peripheral neuritis of the left posterior tibial nerve.

Dr. SAVILL suggested that the symptoms pointed to the existence of syringomyelia, a condition not uncommonly associated with the other.

CASE OF POSTERO-LATERAL SCLEROSIS(?).

Dr. GUTHRIE also showed a man who for six or seven years past had exhibited symptoms suggestive of postero-lateral sclerosis, though the fact that he had several times recovered under antisyphilitic treatment made the diagnosis doubtful. The patient denied any history of syphilis.

NEPHRECTOMY FOR INJURY.

Mr. SWINFORD EDWARDS showed a man, aged 55, who had been brought to the West London Hospital suffering from the effects of a wound caused by falling from the third storey on to some railings. The fall had caused comminuted fractures of the eleventh and twelfth ribs on one side, and in the bottom of the wound, after removal of the clots, the kidney was seen, itself extensively lacerated and bleeding profusely. He ligatured and cut it away, and the hæmorrhage ceased. Some suppuration took place, and for a time there was a high temperature, but ultimately the man made a good recovery. He commented on the fact that on the fourth day the excretion of urea amounted to the normal, and on the fifth day the urine amounted to 50 fluid ounces daily.

PSORIASIS GYRATA.

Dr. SAVILL showed a lad, aged 15, who displayed an eruption on both arms, which began five weeks ago, and developed in the course of a week. It was symmetrically distributed

over the arms and legs and around the mouth. The front of the knees was especially involved. The eruption consisted of red circular scaly patches, healing in the centre and spreading at the margins. The glands of the neck and chin were enlarged. There was no hereditary history, but he had just ascertained that there was a history of a mucous tubercle on the anus, and he was disposed to regard the eruption as syphilitic psoriasis.

CASE OF DOUBLE PTOSIS AND CROSSED DIPLOPIA.

Dr. SAVILL also showed, on behalf of Mr. WARREN TAY, a lad, aged 12, who three weeks ago had suddenly developed double ptosis with crossed diplopia, consequent on weakness of both internal recti. The superintention of the symptoms had been preceded by headache for two or three weeks, and at about that date he had suffered from sore throat for a day or two. No one else in the house, however, had suffered from sore throat.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

A. SYMONS EGGLER, M.B., President, in the Chair.

Friday, November 1st, 1895.

ETIOLOGY AND TREATMENT OF GASTRIC ULCER.

Dr. DONALD HOOD, on opening the discussion from the medical standpoint, said his remarks would be confined especially to considerations on diagnosis in those cases where symptoms are indefinite, ambiguous, and often misleading. He referred to the importance of weighing well the value of the symptom hæmatemesis, and he drew special attention to the careful differentiation between various forms of acute abdominal pain with a view to diagnosis at the earliest possible moment of the existence of perforative ulcer. He gave a brief clinical picture of the most important subdivisions of groups under which gastric ulceration practically came before us for treatment. He cited a case which had been judged to be one of merely prolonged dyspepsia, but which on examination after death proved to have been one of extensive recurrent ulceration, producing much contraction of the stomach, and leading to perforation of the diaphragm. He referred also to a case of acute perforation and severe hæmatemesis in a young anæmic girl, and in connection with this he laid down certain criteria which would help to differentiate cases of hæmorrhage caused by organic breach of the stomach walls from those which frequently occurred in early adult female life without any such breach, a condition for which he proposed the name hæmatemesis puellaris.

Mr. BRUCE CLARKE, introducing the surgical side of the discussion, began by referring to the rarity of perforations of gastric and duodenal ulcer. He described two principal varieties: those in which collapse was the prominent symptom, and those in which the extravasation of intestinal or gastric contents was more gradual. These cases were often indistinguishable from intestinal obstruction, and indeed gave rise to it by the peritonitis which they set up. There was only one keynote to success in ruptured ulcer, and that was early diagnosis and early treatment.

Dr. ALDERSON thought gastric ulceration, when unaccompanied by hæmorrhage and vomiting, was frequently overlooked. He commented on the rarity with which gastric ulcer was assigned as a cause of death, and quoted the Hammer-smith statistics for five years, where out of 8,205 deaths, only 11 were assigned to this cause. He narrated a fatal case from his own practice, in which at an early stage, owing to the absence of definite symptoms, diagnosis was impossible. In this case the patient was an adult male.

Dr. CAMPBELL POPP alluded to the statement of Sohlern that in the Rhone valley, the Bavarian Alps, and in the greater part of Russia gastric ulcer rarely appeared. The inhabitants were mainly vegetarians, and thus got about one-third more potash salts in their food. Having discussed the points of diagnosis between gastrodynia, gastric ulcer, and carcinoma, he laid stress on the value of absolute rest for successful treatment, and for drugs he preferred belladonna combined with bismuth to the preparations of opium. For after-treatment he used arsenic and iron as prepared by Zambetti.

Dr. SKYMOER TAYLOR spoke only of the clean punched-out ulcer, which was found almost exclusively in young women.

He argued that this was an almost constant incident in the clinical history of prolonged cases of chlorosis, and cited authorities who had noticed this connection. He pointed to the common factors of age, sex, and neurosis, and held that neuropathy was the starting point in chlorosis. Further, the ulcer in its appearance and character approaches those ulcerations which are distinctly neuropathic, tabetic ulcers, herpes, etc. He held that the connection was further established by treatment. He maintained that the embolic theory was untenable in view of the splendid collateral circulation of the stomach.

Dr. KERTLEY contrasted the signs of perforation in various situations. He advocated early operation, even at times without waiting for recovery from shock and without an anæsthetic.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

WILLIAM CRAIG, M.D., Vice-President, in the Chair.

Wednesday, November 6th, 1895.

CASES.

Dr. STEWART STIRLING showed a case of Erythema Multiforme (papulatum); also a man suffering from Lupus of the Occiput. Drawings of both conditions were also presented.—Dr. NORMAN WALKER also showed a case of Erythema Multiforme (circinatum), and said that a brother and sister of the patient were, or had been, similarly affected.

PATHOLOGICAL SPECIMEN.

Dr. JAMES CARMICHAEL showed a Preparation from a case of Double Intussusception.

PRESIDENT'S ADDRESS.

The President's valedictory address was, in Dr. CLOUSTON'S absence from illness, read by Dr. GEORGE GIBSON, the retiring secretary. Dr. Clouston began by saying that no member of the Medico-Chirurgical Society now living could take the president's chair without a deep sense of his inferiority in mind and attainments to many of the men who had sat there before him. When he glanced down the roll of their past presidents, and saw the names of Duncan, Abercrombie, Alison, Christison, Syme, Simpson, Goodsir, and Bennett his personal feeling was one of profound humility. They had been presided over in the past, not only by great physicians and surgeons, but by great men. We of the present day could only hope most fervidly that the race of giants that lived in those days was not impossible in the future of the profession. He thought they were justified, as students of heredity, in anticipating that this would be the case. Brain power seemed to come to mankind in waves. In one generation there was an abundance of it, surging up to the highest watermark of past times, and then again there were low tides of mental energy. If it was any consolation to them physic was not alone in the trough of the wave at present. Politics, literature, journalism, law, and divinity were all alike crying out for effectual leadership. Was there no compensation for this state of matters? If no one man made extraordinary advances, were there not ten making moderate advances? Did it not require a generation of plodders to discover the applications of the great principles and generalizations which the mighty of the past had laid down? Pasteur discovered the part which germs played in health and disease, and Lister applied that knowledge, but to get the full value of the application of both doctrines it is requiring hundreds of hard workers and experimenters in every field, so that suffering humanity may reap the full harvest. In the department of psychological medicine Conolly laid down new principles, and pointed out the falsity of certain old doctrines and the futility of certain old practices, but it had needed two generations of ordinary asylum physicians, of plain business committees of asylums, and of hard-working Commissioners in Lunacy so to apply and to extend Conolly's doctrines that those suffering from mental disease should have the full practical benefit of those principles. Dr. Clouston then referred to the good routine work that had been done in the Society during the past two years, and urged that a larger number out of the 360 members should in the future contribute to the general good. He then pictured an ideal medico-chirurgical society, and indicated

how the Society could be improved and made more helpful to the profession. Dr. Clouston concluded with a tribute to three eminent members whom the Society had lost by death during his term of office—namely, Dr. Thomas Keith, Dr. Brakenridge, and Dr. T. A. G. Balfour. He said: "No more marked individuality than Dr. Thomas Keith ever walked the streets of Edinburgh, or contributed, as he did, so brilliantly to the work of this Society. How well we all can picture his keen nervous face, which might have been that of a poet, the 'far-away' look in his honest eyes, the head set forward, the anxious attitude, and the deep earnest voice. I had the privilege of often seeing him when he was in Edinburgh; and, out of my line as it was, he once asked me to be present at an ovarian operation. I was glad I went, for I then saw the true psychology of a great operator of the nervous type, who fully realised that every knife-cut and every stitch might mean life or death to a fellow-creature, whose life was as precious to her as his was to him! Many a time he told me of his sleepless nights and days of anxiety after great operations. It was a flip to one's moral nature to know him, and a great honour for any man to have his confidence. This Society may well mourn his loss, for it was here he came to communicate the successful results of his first series of ovariectomies, when Edinburgh as yet had had no success in that operation. How many lives he saved since then! Dr. Brakenridge has passed away too. We can all remember his opening of our influenza debate three or four years ago—his precise, accurate statement of his case; conscientiousness displayed in every tone of his voice and in every operation of his mind. He was a powerful clinical teacher, a high-minded, earnest man, a subtle, accurate thinker, and a loyal friend. The profession in Edinburgh will never need to be ashamed of itself if such as he abounds here. Dr. Thomas A. G. Balfour was a frequent attendant of our meetings, and sometimes took part in our debates, often coming here after a hard day's drudgery in general practice. I have known him well since the year 1859, and a better man did not live in our city. With all his strong religious dogmatism he was full of charity and full of humour. I always used to tell him he had much of the best of the clerical mind, and some of its defects. Some of his stories were admirable, and his laugh was infectious. He had strong scientific tastes of the old-fashioned observing sort. He was beloved by his many patients, and, beyond a doubt, exerted a powerful influence for good during his long and useful life. He worthily represented those who do the hard work of our profession, and do not always receive an over-abundance of its rewards. If our family doctors were all such as he was, how well we should stand with the public!"

Dr. JOSEPH BELL proposed a vote of thanks to the President for his deeply interesting address, and expressed the hope that his health would speedily be restored.

Dr. JAMES CARMICHAEL seconded.

ELECTION OF OFFICERS.

The following were elected office-bearers for the session 1895-96: *President*: Dr. Argyll Robertson. *Vice-Presidents*: Dr. James Carmichael, Dr. John Wylie, Dr. William Craig. *Councillors*: Dr. Dow (Dunfermline), Dr. W. Russell, Dr. Sloan, Dr. Burn Murdoch, Dr. Clouston, Dr. G. Gibson, Dr. H. L. Calder, Dr. A. D. Webster. *Treasurer*: Dr. Mackenzie Johnston. *Secretaries*: Mr. Hodsdon and Dr. Graham Brown. *Editor of Transactions*: Dr. William Craig.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Friday, November 1st, 1895.

CONOLLY NORMAN, M.D., President, in the Chair.

TWO DENTAL MALFORMATIONS.

Dr. FRASER exhibited: (1) A wisdom tooth in the left lower maxilla. The tooth was turned upside down, its crown below pointing to the interior of the mouth and its single straight fang directed upwards and outwards to the ramus of the jaw. It was a well-formed and developed tooth, perfectly healthy and lodged in a bony cavity, into which it closely fitted. The specimen might be as old as the famous Battle of Clontarf,

for it was picked up some years since at the old Dublin graveyard of Bully's Acre, adjoining the Royal Hospital, during some excavations made near the pillar stone of Brian Boromhe's son, who was buried there. It was brought to his recollection by the recent successful removal of an undescended wisdom tooth lodged in the upper jaw, and causing intense pain to a young gentleman, aged 22, a patient of his, by Dr. Murray. He did not remember any similar displacement, or rather total inversion, of a wisdom tooth yet described, so far as his reading extended. (2) The incisor teeth of a rabbit. In the lower jaw both incisors projected symmetrically, each upwards of an inch in length, and diverging, instead of being in close apposition; they terminated in small, bony knobs, which was not usual in such malformations. In the upper jaw, one incisor springing from the left upper maxilla was curved in a half-spiral outwards, and was nearly an inch long. The other incisor was very small and weak, and passed underneath its companion to the left side. The cause appeared to be a diseased condition of the upper maxillary bone, whence it sprang, which was curious. Whether proceeding from injury or disease it was difficult to decide. Such malformations are not by any means uncommon, and must, as in this case, entail severe starvation to the sufferer.

The PRESIDENT said the malformations resembling these often occurred in rodents.

Dr. BROWN, who prepared the specimens, said many malformations were due to fracture; in this case it seemed to be due to disease.

RUPTURE OF THE HEART.

Dr. E. H. BENNETT presented an example of rupture of the heart, of which the chief interest was that the subject of the lesion (which was caused by the explosion of a bomb which he had in his hands) lived nearly three hours after the accident. The literature of traumatic rupture of the heart was referred to, and the clinical details of the case were related.

Dr. F. NIXON had had a case of wound of the heart resembling Dr. Bennett's in some points. The man stabbed himself over thirty times in the region of the heart, quite a number of the wounds penetrating the heart substance, but only two entering its cavity. He also was difficult to keep in bed. He lived nearly twenty-four hours. He used to suffer from pain about the umbilicus. At the *post mortem* examination Dr. Nixon found the pancreatic duct filled with calculi.

Dr. FRASER thought that the distension of the pericardium brought about the delirious state, just as occurred in cases of rheumatism.

The PRESIDENT said that in any cases of aneurysm rupturing into the pericardium there was no clear fluid. In a case he saw recently the pericardium was full of nearly fluid blood, although the person had died several hours previously.

Dr. BENNETT, replying, said that the man was not drunk. There was no penetration of the pericardium from without. He never before had seen the pericardium distended with blood which was differentiated into serum and clot, as it was in this case. It was not perfectly transparent serum, but rather opalescent. The wound of the coronary vessel communicated with the cavity of the pericardium, but it was very small.

MYOMA OF UTERUS.

Mr. F. A. NIXON exhibited a myoma of uterus which weighed 21½ pounds after removal.

LIVERPOOL MEDICAL INSTITUTION.

PATHOLOGICAL SECTION.

G. G. HAMILTON, M.B., F.R.C.S. Edin., in the Chair.

Thursday, November 7th, 1895.

SPECIMENS.

MR. NEWBOLT showed a specimen of Necrosis of the Jaw from a Polar Bear, which he had obtained from Dr. Harrison, of Clifton. There was no history of injury. The lateral incisors were carious.—Dr. BARENDT showed sections from a case of Xanthelasma associated with Jaundice.—Mr. THOMAS showed sections of Mr. PARKER's case of Coccygeal Tumour; also specimens of sections from a Tumour of the Leg. The primary growth was removed from the skin of the leg of a man, aged 22. The growth consisted of large epithelial cells

arranged in long alveoli, and was not pigmented. The secondary growths in the groin had a similar structure, but were deeply melanotic. He considered the growth to be a carcinoma arising from the abnormal cells of a mole, and not to be an alveolar sarcoma.—Mr. PAUL showed a beautiful series of lantern slides illustrating Villous, Adenomatous, and Carcinomatous Tumours of the Rectum, and a further series of slides illustrating his views as to the nature of Axillary Breast Tumours (four cases).

SUPPURATIVE MENINGITIS.

Mr. CHARLES G. LEE read notes of a case of suppurative meningitis due to chronic otorrhoea, occurring in a boy, aged 12. In this case the mastoid antrum was opened and the lateral sinus exposed; pus was found in the antrum, but the sinus appeared healthy. The patient received no benefit from the operation, and died some three days after it. The *post-mortem* examination revealed extensive suppurative meningitis, the pus lying chiefly in the neighbourhood of the cerebellar fossae, and surrounding the medulla. On section of the petrous bone pus was found in the labyrinth.

DERMATOLYSIS.

Professor BOYCK and Dr. ALEXANDER presented a communication on this subject. The specimen was removed by Dr. Alexander from a young woman. She had been under observation for many years, and it was probable that the tumour was congenital, or started in early childhood. It had steadily increased in size, and at the time of operation formed huge pendulous folds on the side of the neck and chest. Microscopic examination showed that the tumour consisted of a neoplasia of the cutis vera, which in some places reached an inch in thickness. The new growth consisted of delicate but firm fibrous tissue, containing very numerous thin-walled vascular sinuses. There was very marked atrophy of the epithelium and of the sebaceous and hair follicles. Owing to the overgrowth of the corium the sweat glands were far removed from the skin, but preserved their relationship to the subareolar tissue, which was normal; the glands were degenerating. This case of the overgrowth of the corium was compared with the other forms of elephantiasis and molluscum, where the neoplasia commenced as a perineural (elephantiasis neuromatosa), a perivascular, a perilymphatic growth, or consisted in overgrowth of the fibrous bundles in the areolar tissue. It was an instance of the limitation of growth to a special tissue system.

A discussion followed, in which Messrs. ALEXANDER, HAMILTON, MURRAY, PARKER, PAUL, and Professor BOYCK took part.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

A. W. MAYO ROBSON, F.R.C.S., President, in the Chair.

Friday, November 1st, 1895.

CASES AND SPECIMENS.

THE following were shown:—Dr. CHURTON: Blood from Patients with Typhoid Fever, showing absence of leucocytes.—Dr. DE BURGH BIRCH: A Simple Form of Microtome.—Dr. ADOLPH BRONNER: Case illustrating Victor Horsley's Method of Operating in Cases of Extensive Disease of the Mastoid Process.—Mr. W. H. BROWN: Two cases of Dislocation of Astragalus—one with fracture.—Dr. T. WARDELL GRIFFITH: Specimens from two cases of Extensive Haemorrhage into the Pons Varolii. In both cases there was very extensive disease of the kidneys and much cardiac hypertrophy. In one case the vessels throughout the body were atheromatous, while in the other most careful examination failed to reveal any disease of the blood vessels to the naked eye.—Mr. LAWFORD KNAGGS: Case of Double Glaucoma in a young man following on Influenza.—Mr. NUNNRELY: Brain and Temporal Bone from a case of Middle-ear Disease, with Lateral Sinus Phlebitis.—Mr. LITTLEWOOD: (1) Calculus (weighing 4 ounces) with Kidney removed by Abdominal Nephrectomy; (2) Case of Dupuytren's Contraction treated by dissecting out the contracting band; (3) Large Bursa Patellae.—Mr. SECKER WALKER: (1) A Temporal Bone from a patient operated upon two years ago for Extensive Mastoid Disease. The whole of the mastoid process had been hollowed out by ulceration,

and, after having been scraped and cleaned, a flap of skin was reflected from the back of the ear and pressed into the floor of the cavity. Ultimately the whole cavity became lined with epithelium continuous with the open air through the mastoid opening. (2) Specimens from a case of Middle-ear Disease, complicated by Cerebellar Abscess and Phlebitis of Lateral Sinus.

PORRO'S OPERATION.

Mr. MOYNIHAN read a paper on a successful case of Porro's operation. The patient, a dwarf 49 inches in height, had been in labour for twelve hours. Müller's modification of Porro's original procedure was adopted. Both patients did well.

Mr. BROWN mentioned three cases of Caesarean section which he had performed, and said that in considering the success and failure resulting from all operations of this kind, it must be borne in mind that the cases usually occurred in poor people living in insanitary conditions. He thought Porro's operation infinitely preferable to craniotomy or Caesarean section.

Dr. KILNER CLARKE had performed Porro's operation twice, and laid stress on the importance of after-nursing.

The PRESIDENT considered craniotomy unjustifiable, except where the child was already dead. Porro's operation was infinitely simpler, and had the great advantage of preventing a future pregnancy.

Mr. MOYNIHAN, in reply, said that the condition of some osteo-malacic patients had improved after the operation.

PAPILLOMA OF BLADDER COMPLICATED WITH HÆMOGLOBINURIA.

Mr. ATKINSON read a paper on a case of a gentleman, aged 57, who had begun early in the present year to pass blood-coloured urine at intervals. The attacks, which at first occurred about two or three weeks apart, were painless, unpreceded by nausea, rigor, or chill, or any *malaise*. They came on suddenly and departed gradually. The urine was dark and porter-like, even turbid at times, with chocolate-coloured sediment, at other times more reddish; after two or three days it became clear and normal. Mr. Atkinson first saw it in April, and found much albumen, but no blood discs. Paroxysms occurred at decreasing intervals up to June. In July, while at the seaside, patient passed undoubtedly bloody urine, the urethra sometimes blocked with clot. On return in August, Mr. Atkinson, suspecting stone, sounded with negative result. Another day, introducing a silver catheter, clear urine was drawn, but a shred of tissue in the eye of the instrument looked like villous growth. This was followed by brick-hæmorrhage. On August 23rd the bladder was explored through a suprapubic incision, and a fimbriated papilloma with broadish base attached to and about the trigone was found and removed by forceps and fingernail. The patient made a good recovery, and was out on the eighteenth day; the wound healed, and is now (November 1st) perfectly well. It should be remarked that five years ago the patient passed small stone, followed by hæmorrhage; also that he is the subject of syphilitic taint of many years back—now indicated by occasional patches of psoriasis.

The PRESIDENT wished to know whether there was any return of the hæmoglobinuria.

Mr. ATKINSON replied in the negative.

Dr. CHURTON mentioned a case of hæmoglobinuria complicated by syphilis improved by calomel.

Dr. BARRIS refused to believe that there was any connection between the two diseases.

Mr. LAWFORD KNAGGS related a case of a child with syphilitic periostitis, interstitial keratitis, and its knees full of fluid; hæmoglobinuria appeared five years later.

BULLOUS FORM OF URÆMIC DERMATITIS.

Dr. BARRIS reported the case of a girl, aged 17 years, who, after three separate attacks of dropsy due to chronic Bright's disease, developed an almost universal vesiculo-bullous dermatitis, and ultimately died in coma. At the necropsy the kidneys showed advanced parenchymatous nephritis. The eruption appeared three weeks before death, and was accompanied by intense pains in the feet, which were most affected. The planter and dorsal surfaces of the feet were covered by one enormous blister, the fluid contents of which had an

offensive odour. Dr. Barris believed that the bullous form of uræmic dermatitis had not previously been recorded in this country.

Mr. SOLLY (Harrogate) thought that extensive skin diseases might cause damage to the kidneys, and, on the other hand, that kidney disease gave rise to skin affections mainly of the pruritic character, from defective elimination.

Dr. CHURTON had for years looked in vain for eruptions in uræmic cases.

In his reply Dr. BARRIS joined issue with Mr. Solly on both his statements.

INDICANURIA.

Dr. CHURTON read a paper on the utility of testing for indican in the urine. Indican in the urine meant that the putrefactive product was circulating in the blood and tissues, and poisoning them either by itself or by its associated toxins. It was easier to test for indican than to inquire into the probability of this toxæmia by questions as to constipation or diarrhoea, colour, flatulence, etc. Dr. Klein had found that indol was formed by the bacillus coli in meat broth at 37° C., and that a variety of this bacillus produced a toxin extremely fatal to guinea-pigs. It had also been shown that some pathogenic microbes can form their poisons only when products of putrefaction are present. It was not correct to say that disease of any kind involving the intestines was attended by indicanuria. Dr. Churton had demonstrated its absence in some cases of prolonged constipation, typhoid fever, and strangulated hernia. He doubted the existence of persistent, even slight, indicanuria in perfectly healthy persons. As examples of the utility of finding indican in the urine, he briefly described cases of delirium with convulsions; cholera nostras, with collapse; delirium with spasm of certain muscles; supposed typhoid fever (proved by treatment based upon the discovery of excessive indicanuria to be merely faecal toxæmia); diarrhoea, probably from subacute colitis; and gout—in all of which, as in many others, the indicanuria entirely governed the treatment—namely, removal of the contents of the colon, and antiseptics. Washing out the colon—very cautiously if ulceration was suspected; calomel in small doses; salol; a milk diet, variously modified; and stimulants, if required, were the means usually employed. The colon was washed out even when non-inflammatory diarrhoea was a leading symptom, as in the cases of English cholera, for instance.

Dr. TREVELYAN spoke of the importance of examination of the urine for various poisons. Typhoid bacilli had been found in the urine cases of tetany—recorded in association with gastric dilatation—and many cases of migraine, so often seemingly due to stomach derangements, might be due to poisons absorbed.

OBSTETRICAL SOCIETY OF LONDON.—At a meeting on November 6th, Dr. F. H. CHAMPNETT, President, in the Chair, the following specimens were shown:—Dr. CULLINGWORTH: Necrotic Change in a small Uterine Myoma occurring in a young subject.—Dr. GALABIN: CEdematous Fibroid Tumour of Uterus associated with Pregnancy.—Dr. REMFAY: Tubal Gestation Removed before Rapture.—Dr. LEITH NAIRN: Solid Ovarian Tumour, probably Fibromatous. A special general meeting was also held, at which certain of the laws as revised were discussed and adopted.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At a meeting on October 24th, 1895, Dr. PORTER, President, in the chair, Mr. SNELL introduced: (1) A woman with Embolism of the Central Artery of Retina; she had mitral and aortic disease. (2) A man, aged 48, with extreme Myosis, Argyll Robertson Pupils, and loss of Knee-jerks. He had been under observation for eight years in practically the same condition. (3) Traumatic Palsy of both Sixth Nerves. Mr. Snell, in drawing attention to the cases of this injury on record, specially mentioned the valuable papers of Purtscher and Friendwall. Altogether 57 cases were on record, and 17 were bilateral. (4) In connection with the last case, a girl with Bilateral Palsy of External Recti and Double Papillitis. Headache and sickness were the other symptoms suggesting intracranial growth.—Dr. SINCLAIR WHITE exhibited: (1) A case of Trephining for Temporo-sphenoidal Abscess due to suppurative middle-ear

disease. An abscess containing 2 ounces of offensive pus was cleaned out and disinfected. Five days later a second independent abscess was discovered and treated. Although the lad appeared to be *in extremis*, he rapidly recovered after the second operation and is now quite well. (2) A large number of Gall Stones removed from a suppurating gall bladder. (3) A girl, aged 17 years, from whom the Right Astragalus had been removed eighteen months previously for a Myeloid Sarcoma. Excision was done through a single external wound. The resulting foot was both shapely and useful, the girl being able to walk several miles without fatigue. The arch of the foot was preserved, and contrary to what is generally taught there was considerable movement in the new ankle-joint. Dr. Sinclair White had not been able to find a case of excision of the astragalus for tumour on record.—Mr. DAIN JAMES showed a case of Paraffin Acne. Three other boys working in the same mill were similarly affected. One of them said he could always cure it with soft soap and a flannel. While the patient was in the infirmary the eruption almost disappeared without special treatment.—Dr. ARTHUR HALL showed a case of Circumscribed Scleroderma and two cases of Syphiloderma.—Dr. BURGESS introduced a case of Xanthoma Multiplex. The patient was a middle-aged woman who had been deeply jaundiced for over a year from hypertrophic cirrhosis of the liver.—At a meeting on November 7th, Dr. PORTER, President, in the chair, Mr. CUFF showed a young man the subject of Congenital Syphilis, with congenital malformation of both Radii. In each arm the shaft of the bone was absent. The epiphysis of the head could be easily felt on both sides below the external condyles. The epiphysis of the carpal end, small in size, could be distinctly made out on the left side; on the right an indistinct bony mass, abutting on the shaft of the ulna, probably represented the carpal epiphysis dislocated ulnarwards. The position of the hands was peculiar, each hand being dislocated towards the radial side and displaced upwards.—Dr. SINCLAIR WHITE showed a recent successful case of Estlander's Operation.—Dr. ARTHUR HALL showed a case of Lupus Vulgaris which had been treated by tuberculin with satisfactory results.—Mr. PYE-SMITH showed a large Carcinomatous Tumour of the right ovary which had been recently removed by ovariectomy from a woman aged 47. There were extensive adhesions to the bowel and uterus, but no secondary infiltrations or deposits. The left ovary was free. The patient survived the operation thirty hours. Mr. PYE-SMITH also showed a Right Upper Canine Tooth which had been driven up by a kick at football two years before, and embedded in the anterior wall of the maxillary antrum. A year after the injury a sinus formed in the cheek, and had remained open ever since. Recently the lad consulted Mr. West Jones, who discovered the tooth and sent him to the Royal Hospital. The lingual aspect of the tooth was anterior; the fang, which was not quite completely formed, projected upwards.—Dr. PORTER showed an Aneurysm of the Ascending Aorta, which had pressed upon the right bronchus. There was a curious defective condition of the cartilaginous rings in both bronchi (congenital).—Mr. CUFF read the notes of a case of Hemiplegia produced by embolism of the left middle cerebral. At the necropsy there were found recent vegetations on the aortic and mitral valves, general meningitis, an embolus blocking the left middle cerebral at its commencement, and consolidations of the apex of the right lung. The President, Dr. KRELING, Mr. KNIGHT, Mr. PYE-SMITH, Dr. SAMSON MATHEWS, Dr. SINCLAIR WHITE, Dr. BURGESS, Dr. WILKINSON, Dr. ARTHUR HALL, and Mr. CUFF took part in the discussions.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—At a meeting on November 5th, A. BRONNER, M.D., President, in the chair, Dr. J. H. CRAWFORD gave a Microscopical Demonstration of Malignant Tumours, the specimens illustrating not only the different varieties of sarcoma and of carcinomata, but also the various stages of malignancy of tumours.—Dr. SHIACH showed a patient suffering from Melanotic Sarcoma affecting the Skin of the Abdomen below the Umbilicus, the inguinal glands being also enlarged, in a man aged 59. There were no signs of secondary deposit elsewhere.—Dr. H. BRONNER showed a specimen from a case of Kidney Disease due to

Double Calculus. The patient was a man aged 58, of steady habits, who worked till five days before admission. He complained of diarrhoea, vomiting, and loss of flesh. The urine contained a small quantity of albumen; specific gravity 1.000; no casts. The quantity passed in 24 hours was 72 ounces. No signs of malignant disease were discovered. The symptoms whilst under observation were melana, purpuric eruption on arms, legs, and body; dyspnoea. On *post-mortem* examination calculi were found in each kidney. The left ventricle of the heart was hypertrophied, and the aorta was thickened. The case was discussed by Drs. A. BRONNER, RABAGLIATI, and MAJOR.—Dr. RABAGLIATI showed an Ovarian Tumour which he had recently removed. The patient made a good recovery. The diagnosis of the side from which the tumour springs in these cases was discussed. Dr. Rabagliati also showed a stomach with Two Perforations. On abdominal section he had experienced great difficulty in stitching up a perforation of the posterior wall of the stomach, the one on the anterior wall not having been noticed at the time of operation, and only discovered *post-mortem*. Mr. HANCOCK, Mr. CRAWFORD, Mr. HOBBOCKS, and Dr. H. J. CAMPBELL made some remarks, and Dr. RABAGLIATI replied.—Dr. BAMPTON read a paper on the Treatment and Causes of Cold in the Head of Influenza Origin. The common methods of clothing the head and the feet were criticised, and suggestions made, especially as regards the covering of the head. The treatment which the writer had found advantageous for the symptoms met with in influenza were given, stress being laid on rest in bed, warmth, and stimulation. Drs. MAJOR, RABAGLIATI, GOYDER, FARRER, and S. LODGE, jun., made some remarks, and Dr. BAMPTON replied.

MIDLAND MEDICAL SOCIETY.—The inaugural meeting of the Society was held on November 14th, at Birmingham. There was a large attendance of medical men from different parts of the city and surrounding counties; and a most enjoyable evening was spent. The President (Dr. T. Edgar Underhill) held a reception from 7 till 8 p.m. There were shown Dissections and Microscopic Specimens kindly lent by Professor Windle, Dean of the Medical Faculty at Mason College, and Dr. J. Allen, Professor of Physiology. Medical and Surgical Instruments and other scientific appliances and apparatus were exhibited by Messrs. Southall and Barclay, Salt and Son, Philip Harris and Co., and Messrs. Mappin and Co. At 8 o'clock Dr. W. S. PLAYFAIR, Professor of Obstetric Medicine at King's College Hospital, delivered the inaugural address on the Nervous System in connection with Diseases of Women. At the conclusion of the address a hearty vote of thanks to Dr. Playfair for his able and instructive address was moved by Dr. MALINS, seconded by Dr. SAVAGE, and carried with acclamation.

REVIEWS.

LEPROSY IN ITS CLINICAL AND PATHOLOGICAL ASPECTS. By Dr. G. ARMAUER HANSEN, Inspector-General of Leprosy in Norway; and Dr. CARL LOOF, formerly Assistant Physician to the Lungegaards Hospital. Translated by NORMAN WALKER, M.D., F.R.C.P. Edin., Assistant Physician for Dermatology, Edinburgh Royal Infirmary. With numerous photographs and coloured plates. Bristol: John Wright and Co. 1895.

ANY work on leprosy that bears the name of ARMAUER HANSEN claims the respectful study of pathologists and of physicians who have to deal practically with that disease. His coadjutor in this work, Dr. CARL LOOF, is also known as an experienced worker in connection with leprosy. The English translation by Dr. NORMAN WALKER is worthy of the importance of the book.

Within 143 pages the authors have succeeded in giving a statement of all the important facts connected with the disease, including tables showing the proportion of the complication of tuberculosis with the two chief types of leprosy, the proportion of the two chief forms of the disease (the tubercular and anæsthetic-nodular and maculo-anæsthetic of

the author) in different districts, and the results of isolation in Norway. There are five plates showing tuberculous leprosy of two years' duration, tuberculous leprosy of six years' duration, tuberculous leprosy after breaking down of the nodules, maculo-anæsthetic leprosy of two years' duration, and a case of maculo-anæsthetic leprosy after recovery. Eight chromo-lithograph plates illustrate the microscopic appearances of the disease.

The authors trace the progressive effects of the development of the bacillus of leprosy in the cells, and illustrate clearly by their plates the mechanism by which the growth of the bacillus leads to what are recognised as the pathological changes in leprosy tissues. One of the first effects of the appearance of the bacillus is to produce a characteristic effect in the blood vessels. They had once the opportunity of examining a piece cut out of an erythema-like eruption, and found dilated vessels and round cells, and only after a long search a few bacilli. They conjecture that there is deposited with the bacilli a chemical poison which affects the vessels, or that the bacilli produce the poison, and that this poison has its action only in its immediate neighbourhood. The slow subtle action of the bacillus is such that, as they remark, we do not know the earliest symptoms of the disease.

Much attention is given to the distinction between leprosy and tuberculous affections of certain tissues, which seem to have been often confused by previous observers. They conclude from the fact that they had never seen a leprosy bronchitis or mesenteric gland, that there is no leprosy affection of the lungs or of the intestines, and later examinations of special preparations have only confirmed them in this view. Nor have they ever seen either a typical giant cell with marginal nuclei or caseous degeneration in the leprosy tissues.

The fact that all forms of leprosy are dependent on the bacillus shows that the distinction between nodular leprosy and maculo-anæsthetic leprosy (a term which the authors prefer to anæsthetic) is simply one of degree, and it is interesting to learn that in Norway the milder maculo-anæsthetic cases are more numerous in the eastern districts, where the climate is dry, the nodular in the western district, where the climate is moist. Leprous nodes are most frequently found on the exposed parts of the skin, and it is quite possible that the form is determined by climatic influences.

The pathologist will find much to interest him in this book. He will find how well the functions of the lymphatic glands as filters is demonstrated in leprosy glands. The circulation through them is not arrested, nevertheless the glands retain the infectious product, and if it passes one gland it is arrested and retained in the next. Sometimes the quantity of this infection is so small that one or two ampullæ are sufficient to retain the whole of it, indicating that the circulation in the glands does not take place exclusively through the lymph sinuses, but that the lymph reaching the glands must at once enter the ampullæ.

In an interesting chapter on treatment, the various methods and drugs used are reviewed, with the conclusion that in the few cases in which a cure results the cure is not due to the treatment, but is the natural development of the disease.

For the extinction of leprosy we must rely on isolation and cleanliness, the severity of the isolation depending on the habits of the people of the country in which it is applied. The final sentence of the book states that the authors "are firmly convinced that isolation must be carried out in some appropriate fashion."

THE GROWTH OF THE BRAIN: A Study of the Nervous System in Relation to Education. By HERBERT H. DONALDSON. London: Walter Scott. 1895. (Cr. 8vo, pp. 374.)

This work is addressed to the parent, the teacher, and the physician, with the apparent purpose of stimulating rather than giving practical guidance to those interested in education. A large number of anatomical facts, collected from many authors, will not be new to the student of anatomy, but appear in a form which may be convenient to those wishing to make brain structure a basis of their consideration of mental action. The proportions of growth in the body and parts of the brain, as stated on good authorities, indicate the course of development as it proceeds in the child. The

physiological progress of the nervous system and its action on the body are well traced, and form the most valuable part of the work, which is well illustrated by charts and tables showing nerve-muscle reactions.

The last chapter deals with the education of the nervous system. We cannot agree with the author that "by virtue of their powers the cells adjust themselves to the new surroundings," or that in the very young memory is very poor. The most essential principle we need to impress on parents and teachers is that in the earliest stages the young growing brain is acquiring its co-ordination for future work at a great rate, and tending to retain the effects of all the impressions of the environment and of its training, which are largely under our control. The book is well printed, and contains 77 illustrations and 64 tables.

CONTRIBUTION A L'ÉTUDE DE L'ATROPHIE MUSCULAIRE PROGRESSIVE TYPE DUCHENNE-ARAN. [Contribution to the Study of Progressive Muscular Atrophy of the Duchenne-Aran Type.] Par Dr. J. B. CHARCOT. Paris: Felix Alcan. 1895. (Demy 8vo, pp. 159. With four plates. Fr. 5.)

THE object of this monograph, which is one of the publications of the *Progress Medical*, is to show that primary progressive muscular atrophy still exists as a separate disease. Dr. J. B. CHARCOT traces out in a very interesting manner the history of this disease and clearly shows how, by the advance of morbid anatomy, it has been narrowed down by the elimination of primary myopathies, of peripheral neuritis, of syringomyelia, etc. To such a degree has this taken place that some authorities altogether deny its independent existence. Readers of the admirable account of spinal cord diseases by Pierre Marie, in the recent *Traité de Médecine*, will miss a separate description of progressive muscular atrophy as this distinguished observer has purposely omitted it. After giving a useful working division of the amyotrophies, Dr. Charcot relates in detail five cases of progressive muscular atrophy with one necropsy. The lesions found here are minutely described, and are such as are calculated to show the disease to be a primary affection of the anterior horns. The author also relates a case of subacute poliomyelitis with the morbid anatomy. In view of recent investigations it is interesting to note that there were considerable local vascular changes in this case. Owing to the resemblance of the case to ordinary progressive muscular atrophy the author thinks that there may be a subacute form of this disease. He draws particular attention to changes in the white matter found in the neighbourhood of the anterior horns (*faïceau supplémentaire*) in his cases, and compares them to similar changes described by other observers. He looks upon them as being a direct consequence of the lesion in the anterior horns.

This is an interesting monograph, based on personal investigation, well put together and written in the perspicuous style so characteristic of some of the best French clinicians. It is an important and apparently successful attempt to prove the separate existence of the disease in question. Coming as it does from the pen of the son of one of the chief founders of modern neurology, it naturally claims even more than the usual interest.

HANDBUCH DER PRAKTISCHEN GEWERBHYGIENE, MIT BESONDERER BERÜCKSICHTIGUNG DER UNFALLVERHÜTUNG. [Practical Handbook of Diseases of Trades, with especial reference to the Prevention of Accidents.] Edited by Dr. H. ALBRECHT, with many hundred figures. Berlin: R. Oppenheimer. 1895. Sections 4 and 5. (Pp. 157 and 161.)

THE third and fourth sections of this important treatise on trade hygiene are before us. They do not complete the work as originally intended, but leave one section yet to be published. The subject matter of the two new sections scarcely addresses itself to practitioners of medicine. It almost wholly relates to sanitary engineering, and consequently will be especially valuable to medical officers of health and to factory inspectors who have a special interest in machinery, whose principal purpose and functions are to abate the accidents and general drawbacks attending manufacturing operations.

The mode of construction and of action, and the purposes of such machines are copiously illustrated by a host of woodcuts, clear, and sufficiently explained to be comprehended by all who possess rudimentary knowledge of mechanics.

Chapters of wider interest occur, dealing with the ventilation and warming of workshops, with means to moisten the air and to remove dust, and with arrangements to secure warm food for operatives in specially constructed messrooms; with the construction and ventilation of waterclosets, lavatories, and washhouses; cooking apparatus, the construction of respirators, the appropriate clothing of workpeople, the making of protecting masks and spectacles, and many minor inventions to guard against the harmful incidents of trade processes, and the injuries arising from machines of all sorts.

In short, Dr. ALBRECHT and his associates, in producing this work on trade hygiene, have sought to make it exhaustive, omitting nothing from examination and illustration which concerns the sanitary well-being of artisans. Such a work demands a place as a book of reference in every public library, and as a valuable handbook in the libraries of sanitary engineers and medical officers of health. It shows how much time, patience, and study have been expended in Germany in developing the art and science of sanitation, and what great success has been attained.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

BEEF JUICE.

A SAMPLE of beef juice sent to us by Messrs. Fredk. Stearns and Co., 25, Lime Street, E.C., is a well made preparation having all the characters of a high class uncooked beef juice. It is readily miscible with water, rich in soluble meat constituents, and pleasant to the taste. Analysis showed that it contained 34 per cent. solid material, of which 6.5 per cent. was coagulable when the beef juice was heated, 14.5 per cent. meat extractives, and 10.5 per cent. of saline constituents, including added salt.

DIGESTIVE JAMS.

SAMPLES of digestive jams prepared by a patented process have been submitted to us by Mr. W. Hodson, of Tadworth Farm, Epsom. It is claimed that by an entirely new process of manufacture these preserves have been rendered more easily digestible and therefore more adapted for consumption by invalids and others who are debarred from the use of jam prepared in the ordinary manner. The special feature in the preparation of these jams consists in partially neutralising the normal acidity of the fruit, and there is also an addition of pepsin. The results of our examination show that the jam so treated contained about 0.5 per cent. of free acid expressed as malic acid, or only about one-half the amount of free acid normally present in a well prepared jam; whilst the ash amounted to 0.3 per cent. The jam gave no indication of containing active pepsin. The samples were all of good flavour, well made, and from a dietetic point of view the idea of neutralising the excess of acid is a commendable one.

MATÉ OR PARAGUAY TEA.

MR. ARTHUR CUMBERLAND, of Catford Hill, S.E., has brought to our notice maté or Paraguay tea, for use by weak or dyspeptic persons and convalescents, for whom ordinary tea, coffee or cocoa would be unsuitable. The dried leaves of *ilex paraguayensis*, known as Brazilian tea, are extensively employed in South America as a substitute for ordinary tea. They contain theine, the same stimulating alkaloid that exists in tea, associated with a much smaller proportion of astringent or so-called tannin principle. An infusion made with maté in the same way that an infusion of tea is made by tea tasters in determining the value of tea was a pale-coloured liquor of aromatic tea taste, containing in 3½ fluid ounces

10½ grains of extractive. Its astringency was equal to rather more than one half that of an infusion made in the same way with ordinary tea and the theine amounted to 0.3 grain, or less than one third as much as that in a similar quantity of infusion made with ordinary tea. If the dietetic value of tea were proportional to the amount of theine present maté would not be likely in this country to supersede China or Indian tea with ordinary tea drinkers, but it may be useful in dyspeptic cases where ordinary tea is prejudicial owing to the so-called strength or large amount of astringent principle. To increase the usefulness of maté it has been prepared in the form of troches, tinctures, extracts, etc.

THE TREBLE SPRING TRUSS.

DR. JOHN RAMAGE has, after long endeavour, succeeded in designing a steel truss capable of having the pads shifted backwards or forwards, and in which the springs may be readily changed so as to afford a firmer or lighter pressure. This light and elegant appliance, suitable either for inguinal or for femoral hernia (which is made by Mr. Schramm, 24, Great Castle Street, W.), consists of a back pad joined by

metal springs to two pads in front, and is constructed so that its several parts can be detached and any part can be changed or replaced. The truss can thus be made larger or smaller

to meet the patient's requirements, and the springs can at any time be changed for stronger or lighter ones should the hernia increase or diminish in size. The back pad is hinged to the springs, and adapts itself to the spine, being thus conducive to the comfort of the patient, as its position is unaffected by any movements of the body. Dr. Ramage points out that by obtaining a

double set of springs at a trifling extra cost the patient may guard against the danger of the truss suddenly becoming useless through accidental breakage, as the extra spring can at once be used to replace the damaged one. The truss can, with the greatest ease, be taken to pieces, and put together again without the aid of any tool. Mr. Schramm has also made for Dr. Ramage a special apparatus intended for use by the medical attendant, to measure a ruptured

Diagram showing a hand using a special apparatus to measure a ruptured part of the truss. The name 'SCHRAMM' is visible on the apparatus.

patient for a truss. The limbs of this instrument are made of soft metal, and are joined to a back pad. The limbs slide upon each other in front in a metal groove, and one of them is graduated in inches. The instrument having been applied in the position thought suitable for a truss, and pressed into the shape of the subjacent parts, the number beneath the point of the unmarked arm is noted. The apparatus is then carefully removed and laid on a sheet of paper, and a pencil swept round its inner surface. Thus an accurate fit is ensured without the necessity of the patient paying a personal visit to the instrument maker.

REPORTS

ON

THE NURSING AND ADMINISTRATION OF IRISH WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

VIII.—LONDONDERRY WORKHOUSE INFIRMARY.

On arriving in Londonderry we at once sought out the medical officer, Dr. Browne, who kindly promised to show us over the infirmary on the following day. The house, which is of the second class, stands on a hill in the city. The grey stone building, on its platform partly of masonry and partly of natural formation, is a conspicuous object in the landscape, at any rate from the side from which we approached it.

The accommodation for the sick in the infirmary is insufficient for the needs of the union; it was crowded even in the summer. There were 67 patients in the wards, which was a little above the average for the time of year. The infirmary was built sixty years ago. The plastered walls are white-washed, and the beams supporting the roof are rough and uneven, whilst on the ground floor the rafters are unceiled. Small windows on one side, with slit openings in the opposite wall, near the cornice, are the only channels of ventilation as well as of light, and there is no superabundance of either. For these 67 patients there is

ONE NURSE

by day, and she is untrained, so that it is a mere quibble to say that they are not nursed by paupers; there must be pauper nursing, or practically none at all. A night nurse, also untrained, has recently been appointed. The most serious class of cases is not often found among the patients, as some are taken to the County Infirmary in the city; yet our brief glance round showed us a bad case of jaundice, requiring careful feeding; bronchitis, which would be all the better for warmth, regular poulticing, and appropriate nourishment; heart disease in need of watchful nursing and rest; ulcers on the legs after confinement, requiring skilled dressing; and besides spinal disease, paralysis, and senility, patients who need handling and tending like an infant.

THE HARROW BED

is the only bed used in the wards, with straw ticks and pillows; a wide lining of wood is carried round the walls, so as to prevent the bedding touching the plaster; a bucket chair or two are in each ward, a table shelf for two beds, and some chairs. We also saw some box beds for helpless patients; these are filled with straw, which, in the case of a paralytic patient, can only be kept clean by daily renewal, a process costly to the ratepayers, and unhandy for the patient.

THE PAUPER WARDSWOMEN

are chiefly women with illegitimate children, a special nursery being provided in the infirmary for these infants, that they may not be separated from their mothers. This arrangement deprives the infirmary of some space for sick beds. In this infants' ward were eight beds or cots. The infirmary nurse is lodged in a dark room, crowded with necessary furniture, and suggestive neither of comfort nor health. The surgery, a corresponding room, was equally unsuited to its purpose.

THE LUNATICS,

as this class is styled, though it consists mainly of feeble-minded and epileptics, are placed in a separate division of the infirmary. We were pleased to note a distinct improvement in the style of the arrangements made for them as contrasted with those of previously visited infirmaries. The cells are disused, and in lieu thereof the Board has provided dormitories, dining and day rooms, partly on the first floor of the infirmary wings. These rooms are light and cheerful; pictures, plants, and mats give some air of comfort, and we were informed that paid attendants had lately been appointed to each side. The condition of the lunatics in the majority of the workhouses is so scandalous that such slight attempts as these at a more humane and sympathetic treatment deserve favourable comment. We do not, however, mean to convey that the sanitation or the arrangements for the night are as they should be, but the nurse from the infirmary visits these wards during the night. The lunatics themselves looked comparatively clean and happy, and some had some slight occupation such as knitting.

THE AGED AND INFIRM

are in their usual quarters in the end blocks of the body of the house. We noted in our round that there are no conveniences for the old people at night, except pails and buckets; and, furthermore, we ascertained that these wards are locked on the outside at 7 P.M., and not unlocked till 6 A.M. In conversation with one of the officers we were told that if by chance one of these dormitories is visited at night "the stench is very bad," the floor at times being soiled with excreta; as the officer remarked, "the old people cannot be blamed, as there is no light."

The appearance of these wards is not inviting. The narrow beds—about twenty in each ward—are close together; the walls are rough surface, colour washed, the rafters unceiled; a window at either end gives only a poor light through the long room; an old-fashioned fireplace added to the desolate look, and some pictures stuck on the walls did very little to redeem the general dreariness. There are day rooms leading out of the wards, having a long table and benches. In one of these a male inmate was making his toilet, a basin on the table and a scrap of looking glass being the apparatus. The females were in the dormitory, one old woman rambling in her talk; another with club-foot, whose most comfortable position was crouching on the ground. The old men and women and their wards looked cleaner and better cared for than in many other houses which we had visited. The master said that he wished the people in the neighbourhood would kindly send him old magazines and picture papers for his old people; he had not nearly enough for them.

THE FEVER HOSPITAL

was built at a later date than the workhouse, but structurally is on the same lines. It is a self-contained building of two storeys. Four cases of scarlet fever were being nursed in the ground-floor wards; the long wards above were empty. Hair mattresses are in use on a few of the beds in this division; here, also, we saw a bath, and a closet with flush. The nurse (not trained) served for many years in the infirmary wards before she was transferred to this section.

THE INFANTS

are placed in a low building, forming one side of the square. The nursery is a long room with a boarded floor, a fixed bench running round the walls, and a staircase leading to the mothers' dormitory above. The room was tenanted by a solitary little mite crouching close to the fireplace, a true workhouse infant. There were a few wooden cradles at one side. From these insufficient data we were unable to form our own idea of the care bestowed on the infants, but the officer who accompanied us said that as the mothers would tell of one another if the infants' milk were taken, there was no fear of their not being properly fed. The room was clean, but very bare; the rough walls, raftered roof, small windows, and fireplace insufficient for heating the room in cold weather, were not suggestive of a nursery in the proper sense of the word.

THE SANITARY ARRANGEMENTS

are primitive; for indoor service, pails, buckets, or bucket chairs; these remain unemptied during the night. Though

in the infirmary the nurse may put the vessels outside on the landing, there is no closet indoors for the emptying of them. Outside are privies on the waggon system, the waggons being emptied daily on to the land. These places were kept clean as far as they could be. There is a service of cold water on the landings and a small sink for the rinsing of mugs, but there is no slop sink nor wash-up sink nor any bath. A basin and jug is provided for each ward, over which is hung a small roller towel, changed, we were told, "as often as necessary." The same provision for personal cleanliness is also made in the wards for the aged and for the lunatics. The water is drawn from the town supply; the sewage flows partly into cesspools and partly into the town supply.

THE LAUNDRY

is in many respects an improvement on others we have seen; there are drying closets heated by steam, the washing troughs are all provided with service taps, there is a copper in good repair, and the ironing room is over the washhouse. We were surprised at the absence of mangle and wringer; but these machines are evidently not much in favour in this country. In the kitchen all the cooking is done in jacketed boilers heated by steam, hence there can be no roasting or baking of the food. Soup was being prepared for the day's meal. The diets for the infirmary are cooked in the main kitchen, whence the food is distributed to the various sections on wooden trays.

RECOMMENDATIONS.

In accordance with our usual practice, we would gather together the points wherein there is urgent need of alteration, and it occurred to us that if the guardians could provide a separate building for the lunatic class, it would get free wards which might be utilised for the sick, and so relieve the congestion in the infirmary. But the crying need is a staff of trained nurses in sufficient numbers to supplant the paupers, who might be far more usefully employed in the domestic service of the house than in attendance on the sick. One nurse, and she untrained, cannot attend to 67 sick or helpless patients. Baths, closets, and a good hot and cold water service all over the place would lessen the labour and add to the efficiency of the nursing. Day rooms, by providing a place for the patients who are able to sit up, where they could have their meals, where the men might smoke, read, or play games, would diminish the crowding of the wards, and also keep them quieter for the more acutely ill. We would make the same suggestions for the improvement of the infirm wards, improved sanitation, and the brightening of the day rooms, the only home of the old people until they die. Considering the prison-like arrangement at night, there should be bells or telephones from every part to the master's house. Finally, the modern bed and bedding should supersede the harrow bed and straw tick, these latter being most unsuitable for the use of the sick, and being, moreover, liable to harbour vermin.

LONGFORD BOARD OF GUARDIANS.

THE proceedings of this Board have been attracting much attention; there has been a difference of opinion between the guardians and the medical officer on the question of the nursing in the Fever Hospital. The matter is compromised by the Board advertising for an assistant nurse at a salary of £5 per annum! We quite agree with the guardian who remarked, "I don't believe you would get anyone who would pretend to anything for £5 a year—not even a servant girl." If the Board is in earnest in wanting an assistant nurse, this is not the way to set about it. Dr. Cochrane is rather extravagant in his demands; he asks for an attendant for the lunatics, and for better quarters to be provided for them than the existing prison cells; to engage an assistant nurse for the Fever Hospital, and to repair a leaky drain which discharges its contents under the infirmary windows. The medical officer is also dissatisfied with the style of labour employed to carry out these alterations, but as there are no males, exclusive of patients, in the house, the guardians think he surely might be content. It is only a detail that of these 33 there are only 14 under 40; out of these 14, 5 are crippled, 3 are attendants on patients, 1 is an escaped lunatic, and the residuum have the whole of the usual work to carry through.

We notice that our report on the Ballisborough Union is published in full in the *Ocean Weekly News*. We hope it may have the satisfactory effect of bringing about the necessary changes.

INDEPENDENT TESTIMONY.

ACCORDING to a note in the weekly edition of the *Irish Times*, an eminent M.P., a member of the present Government, has been making a personal investigation into the condition of the poor in the three kingdoms. The

result of his visits to the workhouses in Ireland is thus summed up: "The opinion of this gentleman goes far to confirm much of what we have seen stated in the press and medical journals as to the wretched arrangements, or rather want of arrangements, that prevail in our Irish workhouses." We are very glad that public opinion is being directed to this matter, and on our part we promise to emphasize this opinion by the publication of the results of our Special Commissioner's visits to the workhouses of the country.

LITERARY NOTES.

DR. MAX NORDAU has given his literary critics their revenge by the production of a novel, which is published by Mr. W. Heinemann.

We are asked to state that the Rebman Publishing Company, 11, Adam Street, Strand, will be the sole agents in Great Britain for the *American Yearbook of Medicine and Surgery*, which is to be published by Saunders, of Philadelphia, at the beginning of 1896.

The *Illinois Medical Journal* is the name of a new periodical devoted to medicine and surgery, to be published monthly at De Kalb, Illinois, under the editorship of Dr. H. E. Dunlap.

Since July of the present year a medical monthly, entitled *Cronica de Ciencias Medicas de Filipinas* has been appearing in Manila, under the editorship of Dr. Alfonso Maseras.

The editor of the *Quarterly Medical Journal* has arranged for a series of illustrated articles on "Health Resorts." The first of the series, on Harrogate, by Dr. J. Gordon Black, appears in the October number. The second article will be on Bournemouth.

The October number of the same periodical contains the text of Mr. Victor Horsley's introductory address delivered at the opening of the winter session of the Sheffield School of Medicine. The address concludes with the following passage, which we make no apology for quoting, as the highly gifted man to whom it refers was, owing to his contempt for the arts which are the stepping stones to what is called "success," little known outside the circle of his personal acquaintance during his life:

If you ask me for a guide or example, I can at once, though not a believer in hero worship, point to one who was a striking instance of the powerful influence for good that some men evidently exert. I refer to the late Mr. Marcus Beck. He, on his part, was always fond of quoting the words of Guy de Chauliac, the best of mediæval surgeons, whose own description of what an ideal practitioner should be, presents his life and character as those of us who were his pupils and friends knew it, namely:

Bold when sure,
Cautious in danger,
Kind to the sick,
Friendly with fellow workers,
Constant in duty,
Not greedy of gain.

These words are now placed on the memorial to Mr. Beck in University College Hospital, and just as he showed us in his life how true they are, so let us also keep them before us to remind us what should be the character of our life's work.

MEASRS. Macmillan and Co. have issued Dr. Lauder Brunton's Harveian Oration for 1894, "Modern Developments of Harvey's Work," in the form of a bound pamphlet. The substance of the oration was published in the *BRITISH MEDICAL JOURNAL* immediately after its delivery, but many readers will no doubt be glad to have in a convenient form the full text of an address which, like all that comes from Dr. Lauder Brunton's pen, is as readable as it is instructive.

A recent issue of the *Magazine of Music* contains an interesting account of the progress which has been made at Epsom College in the matter of music. For twenty-five years the work has been directed by the Rev. S. J. Rowton, Mus. Doc., and the department grew up gradually and, as it were, spontaneously. It has, however, now been organized regularly for a good many years. The chapel choir consists of sixty boys, and there are fifty-three boys learning various musical instruments. Careful rehearsals are held for an annual concert in Lent term, but the most popular musical event of the school year would seem to be the "house singing." The five houses engage in a musical contest, the competition comprising (1) solo singing, (2) chorus singing, (3) quartet singing. The whole of the musical work would appear to be voluntary, and the success which has attended the experiment of placing opportunities for instruction in their way is a pleasing example of the influence of the liberal arts in softening boys' manners and rendering them less "beastly," as a too literal translator once said.

BRITISH MEDICAL ASSOCIATION. SUBSCRIPTIONS FOR 1895.

Subscriptions to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, NOVEMBER 16TH, 1895.

THE GENERAL MEDICAL COUNCIL AND DIRECT REPRESENTATION.

THE approaching session of the General Medical Council will probably not be a heavy one, inasmuch as the number of penal cases is not large. There are, however, some other questions of great interest to be considered. The November session is that at which the resolutions passed at the annual meeting of the British Medical Association are received by the Council, and this year the registration of midwives and direct representation were the subjects of important resolutions. It is the latter question to which, we think, special attention should be drawn, for the resolution passed in London in August last, instructs the executive "to take immediate steps to have a Bill introduced into Parliament providing that the registered medical practitioners in England and Wales be empowered to elect five additional direct representatives, the practitioners resident in Scotland one additional direct representative, and the practitioners resident in Ireland one direct representative to the General Medical Council." The Council of the Association in October directed that this resolution should be forwarded to the General Medical Council, with an intimation that the means for giving effect to the recommendation were under consideration. This is a grave position. It points to a possible conflict between the Association and the General Medical Council. The Act of 1886 provides that the General Medical Council may at any time represent to the Privy Council "that it is expedient to confer on the registered medical practitioners resident in any part of the United Kingdom the power of returning an additional member to the General Medical Council."

We wish that we could entertain the hope that this course will be adopted. On three separate occasions within the last five years the Council has deliberately rejected it. Twice they declined even to discuss the matter, and on the only occasion on which they allowed a debate they voted against any increase of the representatives of the profession by a majority of 21 to 5.

We must confess that this record makes it seem hopeless to expect any help from the General Medical Council. The Association fought for and won the recognition of the representative principle. After ten years' trial of it the profession declares it a success, and demands a larger representation. It is a just demand all round, but especially so as regards England and Wales; for we find that while Ireland has one

representative for every 2,511 medical men, Scotland one for 3,224, England and Wales have only one for every 7,000 practitioners.

The General Medical Council has existed for nearly forty years, and for twenty-eight years the profession was denied any direct voice in its proceedings. All that time the fees levied on practitioners provided the funds for the Council's work. All that time the profession agitated against its exclusion, and protested that taxation should on constitutional grounds involve representation. All that time the active leaders in the Medical Reform Committee of the British Medical Association cherished the traditional knowledge that if there had been any register of the profession in 1888, the Act of that year would have given direct representation.

Those twenty-eight years in the wilderness of delayed justice, were, in 1886, rewarded by the tardy and inadequate concession of five elected representatives in a council of 80, in which the corporations possess 20 seats, or double the voting power of the independent representatives of the Crown and the profession. It only requires the bare statement of the figures to convince any unprejudiced person that direct representation is practically powerless against the interests of the corporations; bodies which the Council was created to control, and which, nevertheless, have the exceptional advantage of ruling the Council and receiving through their members the larger share of the funds to which they contribute nothing. It is not surprising that a very strong feeling exists that this position is intolerable.

We give the General Medical Council all credit for its great work in improving medical education and maintaining within its powers the discipline of the profession, but it is quite impossible that a constitution so absurdly out of keeping with modern ideas can be left unreformed. The very fact, generally admitted, that the direct representatives, even in their scanty number, have made the Council more active, especially in disciplinary work, makes the demand for a change all the more forcible. That change will have to be made. If made soon it may be confined to the comparatively narrow limits of the resolution of the annual meeting. But even now the opinion is growing that such an increase is quite inadequate, and that nothing but the power to elect a majority of the Council will be a just settlement.

At present by no combination of the other elements of the Council can the corporations be placed in a minority, and yet these bodies, of which more than half have no disciplinary powers over the men they qualify for the profession, practically control the only court empowered to remove a name from the *Medical Register*. The additional members asked for in the resolution of the Association would, we admit, increase considerably a Council which is possibly already too large. The size of the Council and the consequent costliness of its meetings is the only argument of any value that has ever been raised against the increase of direct representation. It is by no means insuperable. The Act of 1888 allowed two corporations to join in electing a single member, and that principle, which in spite of protest was departed from in the Act of 1886, must again be adopted. The present system gives comparatively unimportant medical corporations a voice equal to the greatest, and stimulates more than ever the policy of fighting for individual interests

which has been so well called "the battle of the shops." The Act of 1886, moreover, points out the way by which the amalgamation of corporations can be effected through the Privy Council, just as it points to the same way of increasing the members directly elected. That way is still open. If it is not followed, the Association is bound by the resolution to approach Parliament. In its own interests, as well as in the interests of the profession at large, we urge the General Medical Council by timely concession to avoid a conflict in which it cannot win.

MEDICAL WOMEN AND THE LONDON COLLEGES.

THE Royal College of Surgeons, at its annual meeting on November 7th, followed the lead of the College of Physicians by voting against the admission of women to its examinations. At both Colleges the hostile majority was smaller than might have been anticipated. The Fellows of the College of Physicians who opposed the petition had a majority of 9 out of 109 votes; the Fellows and Members of the College of Surgeons on the same side had a majority of 10 out of 106 votes. The arguments brought forward in both the debates were mainly these: that, as the degree of the London University can be obtained by women, there is no practical hardship in refusing to them the licence and diploma of the Royal Colleges; that the practice of medicine and surgery is beyond the powers of women, even if they can pass the necessary examinations; that, if allowed to enter the Colleges, they might be elected to the Presidents' chairs; and that women have not up to the present time contributed anything important to medical literature.

With a view to these arguments being rightly estimated, the following facts seem to us deserving of attention. In 1894 twenty-six students entered the London School of Medicine for Women, and of this number twenty-three, or 88 per cent., proposed to work for the London University degree. No one contends that women are conspicuously stronger than men in mind or body. Is there any other school in London which could enter 88 per cent. of its students for the London degree with a reasonable chance of seeing them succeed? A large proportion of the 88 per cent. from the women's school will probably fail. Why should women be expected to do what men could not do? The London degree is practically an honours degree. The candidates must have exceptional abilities or they must put up with failures—possibly with many failures—and with spending seven or eight, or even ten years, in getting the degree. Why should the average woman have no choice but to work for an honours degree or to travel to Ireland or Scotland for her various examinations while to the average man the Royal Colleges in London offer what is wanted? Mr. Clement Lucas, in his courageous and excellent speech in the debate at the College of Surgeons, said that after examining at the London University for four years, he believed the average medical woman was sometimes below and sometimes above the average medical man. Clearly he had formed no distinct opinion as to any great difference between them. But when 88 per cent. from one school are contrasted with, perhaps, 10 per cent. or 12 per cent., or less,

from other schools, the average attainment will naturally be lower where the least amount of selection has been made.

The assertion that women are not equal to the highest kind of practical work in medicine, surgery, or midwifery is difficult to disprove, considering the short time during which the medical profession has been fully open to women. As regards medicine proper no proof is possible. Evidence of competence can only be found in the success which individual women meet with in practice. As regards surgery and midwifery, two important pieces of solid evidence can be brought forward in support of the claim of women to be considered competent. The *St. Bartholomew's Hospital Reports* for 1893 gave a list of 32 cases of abdominal section performed in the hospital during the past year. Deducting one case, which was almost in *extremis* on admission, there were two deaths, a mortality of 6.2 per cent. During the same time Mrs. Scharlieb, of the New Hospital for Women, operated upon 34 cases of the same kind, and had also two deaths, a mortality of 5.8 per cent. The numbers are not large enough to be of any great value as statistics, but they are worth noting as evidence of competence. Turning to the question of the fitness of women for midwifery practice, the statistics of the Clapham and Battersea Maternity Charity should be noticed. The medical women in attendance there have conducted nearly 7,000 cases of childbirth; all the obstetric operations have been performed by women, and the total maternal mortality has been nine. Three of the nine deaths were due respectively to pneumonia, started two days before labour began, to erysipelas caught from a lodger whom the patient had been nursing just before labour, and to pulmonary embolism. Deducting these three cases, can six deaths in nearly 7,000 patients be said to show incapacity on the part of women for midwifery practice?

The alarm about seeing a woman possibly elected to the President's chair in either College does not appear to harmonise well with any distinct conviction of her unfitness to hold the diploma of the Colleges. Surely the Fellows may be trusted to elect as their head the most, rather than the least, approved of their body? Is it logical to refuse to admit women to the Colleges on the ground of incompetence and at the same time to urge that if so admitted there is reason to fear that they would be placed by the Fellows upon the honoured roll of their Presidents? Do the Fellows really require to be guarded against themselves to this extent?

It is true that women have so far concerned themselves with the practice of medicine rather than with scientific research or medical literature. It is not difficult to understand that the small number of hospital posts open to them, their exclusion from all the medical societies, and their sense of solitude within the profession would tend to make them slow to write and slow to speak in public on medical subjects. It is, moreover, not necessary to have written a book or to have made a discovery in order to be a good and trustworthy doctor. Very few solicitors, especially if they have a fair number of clients, write law books; why should all doctors be expected to write medical books, or even to write to the journals? How much did Sir Andrew Clark write? How much do the large majority of successful general practitioners write? The reserve which medical women have hitherto shown in this direction

may, in some cases, be cause of regret; but, probably, on the whole, it is in accordance with good sense and good taste. An epidemic among them of *cacoethes scribendi* would be a much more serious calamity than any amount of reticence. Many of the books which issue year by year from the medical press are no doubt of value, but there are occasionally some that tend less to the profit of their readers than to that of their writers, and if women have refrained from adding to the number of books of this class it is to their credit. It will, perhaps, always be more difficult for medical women to work at literature or pure science than it is for most men. Their lives are more complex, they are more exposed to small interruptions, and they are not as strong physically. They cannot usually work as long as men can each day. They have to live by their work, and having done enough for this they must, in many cases, be content to pause. But even if future experience confirms this hypothesis, it will remain true that a woman may be an excellent doctor if she brings to the work she has chosen a sound practical knowledge of medicine and surgery, thorough honesty of purpose, good judgment, and the desire to minister, so far as she can, to the many varieties of human need with which she comes in contact.

Medical women have been already admitted to the British Medical Association by a practically unanimous vote taken amongst 16,000 members of the profession, among whom are included nearly all the Fellows of the Royal Colleges of England, thus reversing the decision of 1878. That the present decision of the Royal Colleges cannot much longer be maintained is indicated by the greatly reduced majority against the memorialists in both the recent divisions since the subject was last discussed.

THE SALE OF POISONS.

Within the last few weeks some important proceedings have been taken to give greater effect to the law relating to the sale of poisons, which has not hitherto been so thoroughly observed as we have on many occasions pointed out that it should be. The proceedings referred to being a natural outcome of the action taken some years ago by Mr. Ernest Hart as Chairman of the Parliamentary Bills Committee of the British Medical Association in regard to medicinal preparations containing poison, commonly and erroneously known as "patent medicines," their initiation affords evidence that the action then taken has had a beneficial influence, while the result now arrived at will conduce to the greater security of the public. The Act of Parliament commonly known as the Pharmacy Act, 1868, was passed "to regulate the sale of poisons" its provisions relating chiefly to retail sales and, in a minor degree, to the dispensing and compounding of poisons: it constituted persons registered in accordance with its provisions the only lawful vendors of poison by retail and, "for the safety of the public," it subjected them to certain obligations to prove their competence for selling, dispensing, or compounding poisons and likewise to observe suitable precautions in carrying out such work, under pain of liability to penalties if those conditions were neglected. In connection with the keeping of open shop for the sale, dispensing, or compounding of poisons, the use or exhibition of the term "chemist," or any qualified and equivalent form of that title, was reserved exclu-

sively to persons registered under the Act, and the assumption of such titles by unregistered persons was made a penal offence.

It is very remarkable that, under these circumstances, the opportunity afforded for internal organisation of chemists and druggists has not been more generally taken advantage of to secure the objects of the Act and, at the same time, advance the interests of registered persons. But such is the case, and there is little doubt that the majority of chemists and druggists have regarded the provisions of the Act rather as interfering with the free exercise of their business than as affording a basis for its protection which might be developed by them almost to the extent of constituting a monopoly. The Pharmaceutical Society has actually been hampered in the performance of its public duty by the antagonism of the trade, and even of its own members, so that it was not until within the last three years that attempts were made to secure such due observance of the law as it is the duty of the Society in its public capacity to enforce. Laxity in the administration of the Act has led to very widespread disregard of its provisions by unregistered persons, and in addition to the sale of secret remedies containing poison, articles such as corrosive sublimate and potassium cyanide have been supplied in a manner dangerous to the public, by unregistered retail dealers styling themselves chemists in contravention of the Act.

The illegality of such practices has now been established by the Scottish High Court of Justiciary in two appeals against adverse decisions given by the Court of First Instance. The use of the title "chemist" by an unregistered person in connection with retail sale of poison is held to be within the statutory prohibition, even when that title is qualified by the words "photographic" or "technical," and one sale of poison by an assistant was held to render the unregistered proprietor of a shop liable to penalty incurred by keeping "open shop for retailing" poison. These decisions are in accord with those which have been given in English courts, and one of the judges before whom the appeals were argued expressed his opinion that the statute does not admit of any other interpretation. But the other two judges were somewhat disposed to take a different view, and in the course of the hearing one of them seemed to think the action of the Pharmaceutical Society was instigated only by a desire to create a monopoly in the spirit of trade unionism. Some Scottish newspapers take a similar view, in apparent ignorance of the fact that the Act imposes upon the Society the duty of regulating the sale of poisons in accordance with its provisions. The Society may be congratulated on the fact that such erroneous ideas are contradicted by the decision of the High Court of Appeal, and it is satisfactory to find that its efforts to bring about a more effective administration of the law relating to the sale of poison are being attended with success.

It is stated that Mr. Asquith and Mr. Corrie Grant have given an opinion adverse to any further action in the case of Miss Lanchester.

The Committee engaged in promoting the late Professor Huxley finds itself of opinion, some members proposing to found a scholarship for the promotion of research, and the question has not yet been settled.

memorial of the divided issue, some id research, at the

THE Bradshaw Lecture before the Royal College of Surgeons of England will be delivered by Mr. N. O. Macnamara on Thursday, December 5th next, at 5 p.m. The subject will be Infective and Tuberculous Osteitis as Causes of Arthritis, and the Importance of their Early Treatment.

SIR JOSEPH LISTER has been nominated by the retiring President and Council for election as President of the Royal Society. The election will take place at the anniversary meeting on November 30th. Professor Michael Foster has been nominated for re-election as one of the Secretaries, and among those nominated for election as members of Council are Sir Joseph Fayrer and Dr. W. H. Gaskell.

THE Committee of the Oxford Hebdomadal Council has invited several ladies interested in woman's education to give evidence on the proposed admission of women to degrees. No action can be taken by Congregation until this committee has reported, and it is not expected that the evidence will be concluded much before the end of Michaelmas term.

LEGISLATION FOR HABITUAL DRUNKARDS.

A JOINT deputation from the British Medical Association Inebriates' Legislation Committee, the Society for the Study of Inebriety, and the Homes for Inebriates Association is to wait upon the Home Secretary at the Home Office, on Friday, November 15th, 1896, at 3 o'clock.

THE TEACHING UNIVERSITY SCHEME.

A MEETING of the teachers of the medical schools in London has been summoned at the Laboratories on the Embankment for 5 p.m. on Wednesday next. A proposal will be submitted to sign and transmit a memorial to the Government at an early date, praying them urgently to take steps for the appointment of a Statutory Committee to carry out the recommendations of the last Royal Commission on the teaching university question.

THE REGIUS PROFESSORSHIP AT DUBLIN UNIVERSITY.

THIS appointment has not yet been made. We mentioned last week that an adjourned meeting of the Academic Council would be held on Friday, November 8th, to consider a technical point, but the summons was cancelled, and the nomination of Dr. Ball came before the Board on Saturday morning. Here a long discussion ensued, and in the end a division was taken on the question whether the nomination should be adopted. The voting was even, four voting on either side, so that the matter is for the moment at a standstill. It is hardly possible that the election can be referred back to the Academic Council, as that body has already declared in favour of Dr. Ball; and it is regarded as highly probable that a further consideration by the Board will only end in the same division. The latter body, however, will meet to-day (November 16th), and if no decision can be reached the question will be referred to the Chancellor of the University, the Earl of Rosse.

FURTHER INCREASE OF DIPHTHERIA IN LONDON.

THE mortality from diphtheria in London showed a further increase last week, and, with one exception, was higher than in any week during the past two years. The deaths referred to this disease in the metropolis, which had been 61 and 72 in the two preceding weeks, further rose to 75 during the week ending Saturday last, November 9th, and exceeded by 32 the average for the corresponding week of the ten preceding years 1885-94. Of these 75 deaths, 55 were of children under 5 years of age, and 18 of young persons aged between 5 and 20 years; while only 2 were of persons aged upwards of 20 years. After distributing the fatal cases at occurred in the Metropolitan Asylums and other hospi-

itals to the sanitary areas in which the patients have previously resided, it appears that 6 cases belonged to Kensington, 5 to Fulham, 6 to Chelsea, 6 to St. Pancras, 7 to Islington, 3 to Hackney, 3 to Poplar, 3 to Battersea, 4 to Camberwell, 6 to Greenwich, and 3 to Plumstead sanitary areas. The number of diphtheria patients in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last was 683, and 112 new cases were admitted during the week.

THE STUDENTS' UNION, QUEEN'S COLLEGE, BELFAST.

THE erection of the Student's Union has been commenced. The total amount raised for this purpose is £8,000, and of this it is proposed to spend £5,600 upon the buildings, about £1,000 on the fittings and furnishing, the balance being left to provide a sufficient sum to tide the institution over the financial difficulties of the first few years of its existence. The plans, which have been prepared by Mr. Cochrane, C.E., of the Local Government Board, are much admired, and it is believed that the new block will be a very handsome addition to the fine pile of buildings belonging to the Queen's College. The Union will contain a large hall for the various College societies, which will be one of the principal features of the building. The contract provides that the Union shall be completed before September 1st, 1896. Subscribers who have not yet paid their subscriptions are requested to do so as soon as possible, as expenses have already been incurred. Remittances may be sent either to the Treasurers, Mr. T. Sinclair, D.L., and Mr. Adam Duffin, LL.D., Northern Bank, Belfast, or to any of the Secretaries, Professor Lettis, D.Sc., Professor Macmillan, M.A., Dr. J. A. Lindsay, and Mr. R. T. Martin, B.A.

ANTISEPTICS IN FOODS.

THE recent prosecution for selling orange wine containing a little over 3 grains to the pint of salicylic acid suggests the propriety of discussing shortly the general question of preserving foods by antiseptics. Wines are sulphured and doctored with salicylic acid, fluoroborates and fluosilicates; to milk in hot weather all sorts of antiseptics are added, the chief being boracic acid, varied of late by the addition of formalin. Boracic acid or borax is also the favourite antiseptic for butters. It may indeed be stated generally that all decomposable articles not sterilized by boiling, or preserved from change by cold, are liable to be treated with small quantities of antiseptics. There may not be in any one article a percentage sufficient to cause, when given in a single dose, appreciable effect, but a person taking boraxed milk and butter for breakfast and tea, and a salicylated wine for dinner, will be consuming day by day a sufficient amount of active drugs to produce some effect on his health. Salicylic acid is a poison. In 1878 a case happened in which so small a dose as 3 grammes (46 grains) caused death in 40 hours; possibly the acid was impure. In three other cases in which decided and dangerous symptoms were produced the dose was much larger, being 15, 22, and 50 grammes respectively.¹ Salicylic and benzoic acids are, therapeutically, attenuated phenols. Phenol being most poisonous, then comes salicylic acid, and lastly, benzoic acid. It is no sufficient answer to accusations under Section 6 of the Sale of Food and Drugs Act to prove that single large doses of a particular addition have been taken by a number of persons without injury; nor indeed is it an answer if such addition is really proved to have been beneficial to health. The question is narrowed down as to whether the nature and quality was that which was demanded by the purchaser. An individual might have no objection to drink a salicylated liquid, always provided he knew that salicylic acid was there, but he would naturally feel aggrieved at buying an article which he believed to be pure if he found it to contain a foreign chemical substance. What

¹ Kobert, *Lehrbuch der Intoxikationen*. Stuttgart, 1893.

the effect of small doses of salicylic acid, say 5 grains daily, may be at present a matter of conjecture; we know that most of it is excreted by the kidneys united with glycocholi, and also that it is a substance which readily enters into combination, forming a variety of aldehydes and esters, the physiological effect of which are not precisely the same as the free acid. It is conceivable that small quantities of salicylic acid when they come in contact with the intestinal and gastric juices are in this way changed. It is also possible that long bottling of a wine with salicylic acid will change the acid into salicylic ester or salicylic aldehyde. Schmitt, for instance, has found that although Rhine wines are sulphured the old Rhine wines contain no free sulphurous acid, the greater portion having combined with aldehyde, forming aldehyde-sulphurous acid. Be this as it may, the growing use of antiseptics constitutes a possible danger to health. Persons with sound excretory organs have for years daily taken chemicals of the kind in their food without injury, yet it can be confidently predicted that other persons with damaged or weak kidneys will be affected by minute doses. It must also be remembered that digestion in the intestines is carried on to a great extent by what, outside the intestines, would be recognised as a fermentative or putrefactive process. In short, just as the nourishment of a number of plants depends on the microbes around their rootlets, so the assimilation of our own nourishment depends to a large degree on the activity of hosts of colonies of microbes in the intestinal canal. All antiseptics, even in minute quantity, will inhibit the activity of these colonies or affect unequally various species, the net result in ordinary individuals being an impairment of digestion or an actual dyspepsia. The time has apparently come for some definite action with regard to antiseptics in foods and beverages. They should be absolutely prohibited unless a label be placed upon everything sold after being thus treated, stating the nature of the preservative in as large type as any other announcement. Then if the public like to take daily small doses of salicylic or boric acids or of formaldehyde they can do so, but with the immense advantage of knowing what they are consuming.

UNDERFED SCHOOL CHILDREN.

At the end of last year the London School Board appointed a special committee to ascertain the number of children attending the school insufficiently fed, and to make suggestions in regard to providing any further remedy for the same. This committee have now presented their report, in which they recommend the keeping of a "continuous record" of all children receiving charitable meals through the agency of the school staff. A minority report is presented by Mr. Diggle and Mr. Sharp, which ends by saying, "What is needed for the work is not more book-keeping, but more generous sympathy." This raises the whole question of organised *versus* irresponsible charity, but surely it ought not to be impossible to retain all the benefit of the free gift, while gaining the indubitable advantages which may be derived from keeping a careful record of the recipients; and in fact the line of philanthropy suggested by the committee in their report should, we think, relieve them from all reproach on the ground of want of sympathy. Attention is especially directed to the change which has taken place in late years in the manner in which the pinch of poverty is most felt. It is pointed out that food is now so cheap and rent so dear that, whereas formerly actual starvation was the chief evil to be feared by the very poor, now the conditions have changed, and a family may be suffering severely from poverty, and may be deplorably situated with regard to house room, sanitation, and clothing, while yet able to obtain a sufficiency of coarse food. It therefore becomes apparent that if lists of those whom it is desired to help are carefully kept and carefully followed up, it may often prove that medical advice, a gift of clothing, or help to the breadwinner in obtaining or in keeping work, may do infinitely more good than even regular daily meals continued for several

weeks. It is pointed out also that, in the economy of a poor household, help that may be relied on is worth many times more than a casual gift, and that much suffering may be caused if a meal is expected and not received. It is therefore urged that it is often better to grant meals for definite periods after consultation, if possible, with the parent, than to choose each morning the recipients of the day's tickets. A proper use of the "continuous record" will, it is hoped, also lead to the detection of many cases of neglect, not necessarily among the very poor, which at present go undiscovered. Such cases would call for the interference of the Society for the Prevention of Cruelty to Children, and in fact it is proposed to accept an offer, made by the Rev. Benjamin Waugh, to the effect that one of the inspectors of that Society should be appointed to a selected district, in which he may follow up the cases, in order that it may be seen how far the underfeeding of children is the result of parental neglect.

THE COST OF THE ANNUAL MEETING.

THE Treasurer's statement of the receipt and expenditure of the last annual meeting of the British Medical Association is reassuring to towns and localities which have, we believe, been debarred from giving invitation for the ensuing annual meeting by the fear that after the lavish expenditure on the London meeting any subsequent meeting might show to disadvantage. It is, however, satisfactory to know that one half of the subscriptions received for this great assemblage have, notwithstanding the large expenditure on public receptions and on the dinner, been returned. There are also many items which would not enter into any ordinary meeting. Thus, the Ladies' Reception Committee cost £262, the badges for members £41. The cost of the local entertainments, which were arranged on a large scale, but of which the attendance was reduced by the unusual attractions of the great city, ran up to £691, whilst only £800 were received for tickets sold. This, of course, is not likely to occur elsewhere. £290 were spent on the dinner, in addition to the price of the tickets, and there were eighty-two guests. The expenses of the annual meeting, as a rule, bear a direct proportion to the size and importance of the centre, though something will depend on the amount of hospitality shown by the municipality and other public bodies. The annual meeting at Birmingham cost, in round numbers, £260; at Nottingham, £386; at Newcastle, £338; at Bournemouth, where the circumstances were somewhat exceptional, £649. The attendance is governed very much by the facilities of access, and not in proportion to the increase in the number of members of the Association. On the whole, the facts as to receipts and expenditure show that with ordinary care in an average town the expenses need not be at all considerable. We are glad to think that, although lavish expenditure on such an occasion well becomes this great and wealthy metropolis, it is by no means a necessary or even desirable element of the ordinary annual meeting of the Association.

THE SICK POOR IN IRISH WORKHOUSES: LONDONDERRY.

At a recent visit to the workhouse of the Londonderry Union our Commissioner found somewhat less squalor, neglect, and inhumanity than in other places previously seen. The feeble-minded and epileptics have paid attendants and comparatively comfortable quarters. The sanitary arrangements, though primitive, are not so indubitably foul as they appear to be elsewhere; but in spite of official denials, the nursing of the patients is practically in the hands of the paupers. Let our readers judge: There were 67 patients in the infirmary or hospital department on the day of the visit; for these there is one nurse by day and one (recently appointed) by night, the last having, in addition to her duties to the sick, the supervision of the feeble-minded at night. Neither of these women is trained. The

patients included cases of jaundice, bronchitis, ulcerated legs, spinal disease, and paralysis. It is obvious that the duties of the single nurse (for there is only one at a time on duty) must be largely confined to supervision; she cannot attend personally to the wants of 67 patients; and this, be it observed, is supervision of the incompetent, possibly of the unwilling, by the untrained. The pauper helps are mostly mothers of illegitimate children, not people whom, as a class, whatever may be said for an occasional individual, one would choose for a post of trust. What is likely to be the standard of nursing adopted by an untrained woman who has such assistants to depend on? All this is urged in the cause of humanity, but from the point of administration we wish further to note that only in the Poor-law establishments is the custom upheld of employing unskilled labour to do skilled work; the principle is faulty from the economic point of view, wasteful and impolitic, in the survival of a time when the general orders were more matters of experiment than experience, and yet, though experience decides against the custom, it dies hard.

THE COMING ASHANTI WAR.

THE proposed military expedition against Kumassi will probably be a much smaller affair than that of 1873-74, when the town, after considerable fighting, was taken and destroyed. Promptness is, however, of the greatest importance, for, although the distance of Kumassi from the coast is not great, being, in fact, only 120 miles or thereabouts, the country is heavily wooded, and in the wet season very unhealthy to Europeans, especially along the lower levels. It is very desirable then that what work there is to do should be got through between the two rainy seasons. It will be remembered that in the last Ashanti war the capital was taken on February 4th, and burned on February 6th, but still the force employed was caught in the rains, so that there evidently is no time to be lost. What with Maxim guns, rockets, and repeating rifles, even a small British force need have but little fear as to the result, so far as mere conflict with the enemy is concerned, but these tropical expeditions are always to a large extent "doctors' wars," and in regard to the treatment of malarious diseases it may be doubted whether any advance has been made during the last twenty years at all comparable to the progress which has taken place in arms, material, and equipment. Much will depend on preventive measures, the choice of camping ground, a proper commissariat, and especially on pure water. The expedition must, of course, succeed from a military point of view, but the expense both of life and money will depend mainly on the medical department, and the extent to which its efforts are supported. We learn with satisfaction that a supply of portable Pasteur filters of large output, have already been provided for field use, and in adopting the means of purifying water now recognised as most reliable, apart from boiling, a repetition of the single blot on the Chitral expedition should be prevented. The farther arrangements for the health of the force will be watched with interest, and in this doctor's campaign the Army Medical Department will have the best wishes of the entire profession. We have reason to believe that Surgeon-Colonel W. Taylor, now P.M.O., Dover, will be the Principal Medical Officer of the expeditionary force. Brigade-Surgeon-Lieutenant-Colonel Townsend and nineteen medical officers, A.M.S., of different ranks are under orders. A hospital ship will be equipped for the sick of the expeditionary force. Three hundred British troops are at present told off for the expedition.

THE CHILDREN'S INCUBATOR.

THE Liverpool Workhouse Committee have decided to act on the recommendation of the medical officer that an incubator should be provided for infants. The doctor reported that many babies who were taken to the workhouse died from want of vital heat, and that with an incubator many

lives might be saved. It was resolved to procure one to hold four children, which will be kept at a uniform temperature by means of hot water apparatus. There is no doubt of the utility of the incubator in the case of prematurely born children. Such children not only cannot withstand the influence of cold air, but cannot keep up their own body warmth. To keep them alive heat must be supplied to them. There are two incubators at present in the market. Hearson's "thermostatic nurse" is a most ingenious apparatus, by which the air in a box is kept at a uniform temperature by an automatic arrangement, which turns off the heat when the air gets hotter than a certain temperature. The apparatus can be adjusted so that it shall do this at any required temperature. This can be seen in action, hatching chickens, in the Regent Street shop any day. Applied to the rearing of poultry it acts perfectly. Its cost is about £20. In the case of babies its drawback is its cost, and that it is possible for a clumsy, meddling nurse to put the mechanism out of order. It is, moreover, a doubtful advantage for the nurse to think that she can put the baby in it and leave it for an indefinite time without attention. Auvard's is a simpler thing, and costs about £5. It is a box kept warm by hot bottles, or a hot water tank, underneath it. A thermometer in the box shows the temperature. Moist sponges prevent the air from getting too dry. A little louvre indicates that ventilation is right. The disadvantage of it is that hot water must be supplied every half hour. Hence, if used in private practice, there must be two nurses, a day and a night nurse. The expense involved in procuring an additional nurse makes the cost of the two incubators about the same. Some may think the necessity of such frequent attention to the child's requirements is a drawback, but some will hold it the reverse. The larger incubators used at the Paris Maternité, in which several children can be put, naturally do not need warming at such short intervals. Both incubators, Hearson's and Auvard's, were exhibited to the Obstetrical Society of London when they were first brought out. The child should be kept in the incubator till it is as large and as strong as an average full-time child.

DEATH OF DR. BATTEY.

THROUGH Sir Spencer Wells we have received by cable the information that Dr. Battey died at his home, Rome, Georgia, U.S.A., on November 8th. His name is well known, for, like Pirogoff, Syme, Lisfranc, Porro, and others, it is associated with an operation. In 1872 he announced in the *Atlanta Medical and Surgical Journal* that on August 17th of that year he removed the ovaries, still in a state of functional activity, from a young lady who had suffered serious detriment to her health and peril to her life by reason of an excessive menstrual molimen, which was wholly unrelieved by the usual menstrual flow. Hegar, it is true, had removed the ovaries for intolerable ovarian neuralgia on July 27th, 1872, not a month before the date of Dr. Battey's operation. Of course, the latter authority knew nothing of Hegar's attempt, so the operation, like the discovery of the planet Neptune, may justly be credited to two different persons. Dr. Battey did not shun publicity. To him and to Hegar is due quite a new class of operation. Mr. Lawson Tait first removed the normal ovaries for checking hemorrhage in fibroid disease of the uterus, on August 1st, 1872, a date midway between those of Hegar's and Battey's operations. The experience of over twenty years has shown that the removal of normal appendages has its uses. Altogether Tait's principle, in respect to his operation just noted, has prevailed, for many reliable authorities find that fibroids may be rendered harmless by the removal of the ovaries. The question is not absolutely settled. Some observers believe that some obscure morbid process occasionally goes on in ovaries where the uterus is subject to myoma, and it is then alone that their removal proves beneficial. Dr. Battey's practice has been extended, and, unfortunately,

much abused, nor do his principles find acceptance at the present day. He cannot be blamed for the pernicious zeal of others. In 1887, long after removal of the ovaries for neurosis had been widely condemned, he read an important statistical memoir at a meeting of the American Gynecological Society. His tables deserve scrutiny: they were drawn up on the most honest principles. Fifty four operations were recorded, 38 being written down as "cured," 8 "much improved," 5 "little improved," and 8 "not improved." Besides the tables a short abstract of each case was published in the *Society's Transactions*. As to the historical patient operated upon in 1872, Dr. Battey declared that she had been under his frequent personal observation for fifteen years afterwards, her health being completely restored. His supporters and critics must bear in mind his assertion, made in 1887: "The term Battey's operation includes this idea, namely, the importance of the artificial change of life as a remedy for disease, and is so generally understood and accepted by the profession, while the various synonyms 'oophorectomy,' 'spaying,' 'castration of women,' etc., do not convey this meaning." The tables only include 1 case of myoma, which ought to have been excluded; 39 are put down as "chronic oophoritis," but the pathological state of the ovaries is not explained. Hence most were probably cases where old inflammatory changes may have caused trouble, operation being justifiable; 4, however, of the 39 were associated with grave neuroses, and together with the remaining 14 represent a practice no longer in favour, neuroses such as epilepsy existing where the ovaries were presumably healthy. Nevertheless, Dr. Battey acted on scientific principles, and undoubtedly extended the area of abdominal surgery. Those who condemn his operation should bear in mind two facts. The greatest surgeons have advocated operations which, like Battey's, were only discarded when experience belied theory. The treatment of neuroses associated with the pelvic organs and of chronic inflammatory affections of the ovaries remains highly unsatisfactory. Since 1872 more than one method has come into vogue far more objectionable in many respects and not more successful. Dr. Battey was a sincerely pious man, and, like many of his countrymen, was a minister of the Gospel as well as a doctor. He was much respected in the city where he lived and practised.

DIPHThERIA ANTITOXIC SERUM IN LONDON.

THE supply of antitoxic serum by the laboratories of the Royal Colleges of Physicians and Surgeons to the Metropolitan Asylums Board for the treatment of cases of diphtheria was commenced on September 1st, and during the first five weeks 700 doses were delivered. Dr. Sims Woodhead hopes in future to be able to meet all the demands of these hospitals, which, however, are larger than was anticipated. In future, therefore, the hospitals of the Metropolitan Asylums Board will make use of this new serum, and the moment seems to be appropriate to urge on the Board the propriety of publishing with as little delay as possible a report embodying at least the statistical results so far obtained. We are informed that over six months ago the managers received an offer from the medical superintendents of their hospitals to the effect that they would be glad, after the lapse of a sufficient length of time, to present a joint report containing clinical observations and statistical tables, together with the conclusions which they might severally or collectively have reached. The medical superintendents appear to contemplate a very elaborate, and probably a very lengthy, document, which must take a long time to prepare. The profession will be very glad to learn the experience and the opinions of the medical superintendents, but it is, we believe, generally felt that the medical profession and the public have a right to ask that the experience acquired by the officers of the Board should be placed at the disposal of the profession within a reasonable time, and in particular that the statistical results should be made

known. If it be true that these results have not been so favourable as the successes in the earlier months of the treatment gave reason to expect, there is all the more reason that the facts should be made public, and the reasons for a want of success, confined apparently to this country, ascertained.

MEDICAL MAYORS.

IN the list of Mayors elected in the principal cities and towns of England last week we note the names of T. W. Thursfield, M.D., F.R.C.P., J.P. (re-elected for Leamington), and Dr. Townshend Chambers (Wareham). Dr. T. W. Thursfield is the son of a medical practitioner of Kidderminster, and was born in that town in 1839. He was educated at King's College School and Lancing College, and studied medicine at Aberdeen, where he took his Doctor's degree in 1860. After travelling extensively for some years he settled in Leamington, where he has lived for thirty years. Having become a Member of the Royal College of Physicians in 1881 he relinquished general practice. In 1882 he was elected Physician to the Warneford, Leamington, and South Warwickshire General Hospital, and he is Consulting Physician to the Leamington Dispensary, and to the Midland Counties Home for Incurables. In 1880 he was elected a Fellow of the Royal College of Physicians. He has been a member of the British Medical Association for nearly thirty years, and he is a past President of the Birmingham and Midland Counties Branch. Twelve years ago Dr. Thursfield became a member of the Town Council of Leamington, and last year he was unanimously elected Mayor. He is a Justice of the Peace for the county of Warwick and for the borough of Leamington. Dr. Henry Francis Townshend Chambers, the new Mayor of Wareham, studied medicine at the University of Edinburgh, and took the triple Scotch qualification in 1889. He is a member of the British Medical Association and a Surgeon-Lieutenant in the 1st V.B. Dorset Regiment.

THE DUTIES OF REGISTRARS OF DEATH.

WE have received from Dr. Hugh Woods copies of a correspondence which has lately taken place between him and the Registrar-General in regard to a case details of which were given by him in a letter in our columns on November 2nd. The important sentence in the letter of the Registrar-General is as follows: "Registrars are instructed to report to the coroner, not only cases to which in their judgment suspicion attaches, but all cases of death by poison, drowning, burns, suffocation, fractures, contusions, cuts, gunshot wounds, and other injuries whether occasioned by accident or otherwise. This instruction applies to all cases, both those certified by a registered practitioner and others; and cases of death after an operation should certainly be referred to a coroner, leaving it to him to decide whether an inquest is or is not necessary. No reflection whatever on the skill of the medical attendant is intended by such reference, but the responsibility on a registrar of deciding whether a case should or should not be reported is a heavy one; and the Registrar-General is not disposed to censure any registrar for unnecessarily submitting a case to the judgment of a coroner. The Registrar-General would rather encourage all registrars to take this action in more cases as to which the slightest doubt rests in their mind whether they come within the category of deaths which must be so referred to the coroner; and, if necessary, he will take an opportunity of adding to the list of cases in the regulation issued for the guidance of registration officers, in which the reference to the coroner is to be deemed indispensable." Dr. Woods, in his reply, observes that the statement with regard to the reference of cases of death after operation to the coroner is amazing, and points out that such procedure would be most highly objectionable. We can hardly suppose that the consequences have been fully considered by the Registrar-General. So long as

coroner's methods are what they are, so long as the preliminary inquiry is entrusted to uneducated officers or to policemen, such a mode of procedure would be intolerable.

MR. CORONER WYATT AND THE POLICE.

AN inquest was recently held by Mr. G. P. Wyatt on the body of an old man who, having got drunk in the Borough on a Saturday night between 9 and 10, was locked up until 5 a.m. on Sunday, when he made some complaint about his arm. The divisional surgeon was sent for, carefully examined him, and advised that his relatives should be sent for, and that he should be allowed to go out on bail. At this time there was, according to the evidence of the surgeon, no sign of any dislocation, but thirty hours afterwards, when the patient was admitted to St. Saviour's Infirmary, the right shoulder was found to be dislocated, and the right side of the chest and arm contused. The necropsy showed that the man was a drunkard, and the evidence of four police inspectors at the adjourned inquest, as well as the man's own statement to the surgeon, left no doubt that he was drunk on the night in question, yet the coroner allowed a charge to be made against the police of having arrested this man, "of very sober habits," on a charge of drunkenness; and, when asked if there was any police evidence, replied, "I believe not." As he had himself only to request the attendance of the police to be sure of having it, this answer was a little misleading to the jury, who thereupon began to make exclamations against the police. Mr. Wyatt would, we think, consult his own dignity better, as well as preserve the best traditions of his office, if he endeavoured to secure to all parties interested, on every occasion, a fair hearing.

THE SIZE OF FLUSHING CISTERNS.

IN the inquiry which is in progress in regard to the demand of the London County Council that a larger flush of water than 2 gallons per cistern should be given to dwelling houses in the metropolis a great point was made of the large increase which the change would involve both in the amount of water and in the capacity of the drains. Mr. Pember went on to declare that nowhere was there greater waste of water than in London and nowhere were the sanitary fittings of the houses less perfect. In regard to the sanitary fittings we certainly sympathise with the water companies almost as much as with the tenants, but so far as waste is concerned we would point out that an efficient apparatus which will do its work thoroughly with one flush of even 3 gallons is much less wasteful than one ostensibly using only 2, but in reality requiring to be used again and again to produce the desired effect. A cistern which will not fill in the average time during which a closet is required certainly should not be accepted as efficient by the sanitary authorities, while one which will do so is sure to be used twice over if one flush is not effectual. Hence it appears probable that the waste complained of is partly, at any rate, due to the smallness of the cistern, and might be to that extent lessened by the provision of a better flush.

NURSES IN THE IRISH WORKHOUSES.

WE cannot take up a newspaper without noticing how much the question of the nursing of the sick pauper is being pressed on the local authorities; we say "pressed," for we gather from a careful perusal of the reported proceedings at the guardians' meetings that as a rule these bodies regard the employment of trained nurses as an unwarrantable waste of the rate-payers' money. The arguments used are those that, having been worn threadbare on this side of the Channel, are now reappearing in new dress in Ireland: why change the order of things which has gone on for so many

years? why provide a trained nurse when there are so many unemployed inmates who must be maintained in the house? why is the pauper to be nursed when the small ratepayer cannot have such a luxury? why have a nurse on at night when the inmates are so kind to each other during the night? and we are sorry to see that in many instances these arguments carry the day. As for changing the order of things, that is done every day to the manifest good of the community—witness the railways. Then the trained nurse is a distinct economy, as she does the work in a business-like manner and with economy of material, with the result that the pauper is cured, instead of being maintained by the rates for the rest of his life. The small ratepayer would be doing the best for himself if he came into the workhouse hospital to be nursed by the skilled nurse, thus averting an illness that may assume a chronic form. Whether the inmates are kind or not to each other at night is beside the question, though we take the liberty to doubt the assertion, but they have neither the knowledge nor the strength to perform the arduous work of night nursing; and moreover, we fail to see the advantage of skilled nursing by day if it is to cease with the evening.

ARGON AND HELIUM IN MINERAL WATERS.

ARGON is reported to be present in some mineral waters, such as those of the simple thermal springs of Wildbad. Quite recently helium in addition to argon has been discovered in the sulphuretted waters of the Griffon spring, near Caunterets, in the Pyrenees, by Professors Bouchard and Troost, of Paris, who, judging by certain lines in the red and orange portions of the spectrum, infer also the presence of another unknown substance. We may remind our readers that on January 31st last Lord Rayleigh and Professor Ramsay read a paper before the Royal Society in which they discussed the nature of argon, a gas or mixture of gases which they have succeeded in separating from atmospheric air. One of the lines of evidence by which they proved the presence of argon in the atmosphere was that the density of "atmospheric nitrogen" was found to be higher than that of "chemical nitrogen" prepared from different compounds. This led to the conclusion that a heavy gas was present in the air. Many other lines of evidence helped to show that this heavy gas was argon. As the solubility of argon in water is higher than that of nitrogen, it is not at all surprising to hear that the former should be present in the waters of Wildbad and other waters fairly rich in nitrogen, both the nitrogen and the argon in these waters having in all probability in the first place been absorbed from atmospheric air. Indeed, one of the arguments confirming the discovery of argon as a distinct substance was that its solubility in water being said to be higher than that of nitrogen it was to be expected that the density of the mixture of argon and nitrogen, pumped out of water along with oxygen, should after the removal of the oxygen exceed that of atmospheric nitrogen—a conclusion which direct experiment showed to be correct. On April 25th and May 2nd Professor Ramsay read papers before the Royal Society on helium, a gas to be obtained from cleveite and probably from some allied minerals, lighter than any known gas except hydrogen. A comparison of the spectra of helium and argon showed that they possessed certain lines in common (chiefly in the red portion of the spectrum), and suggested that both argon and helium might be mixtures of substances, the coincidences in the red lines of the spectrum being due to their possessing some constituent in common. On the whole, it does not seem probable that a substance like argon, constantly present in atmospheric air, can when present in mineral waters exercise any special therapeutic effect or in any way help to explain the action of these waters. As regards the therapeutic significance of helium in mineral waters, it would be premature to say anything.

ITALIAN SURGICAL CONGRESS.

Serumtherapy in Tuberculosis.—Laparotomy in Tuberculous Peritonitis.

THE tenth Congress of the Italian Surgical Society was held in Rome from October 26th to the 29th, under the presidency of Professor D'ARONA, and it was attended by many of the leading surgeons in Italy. Professor DURANTE, the President of the Executive Committee, in his opening address, dwelt on the great importance of the Congress. Many interesting and able papers were read, and some of them gave rise to considerable discussion. The majority of the communications dealt with surgical tuberculosis and cerebral surgery. An important communication was made by Professors MAFFUCCI and Dr VASTA on Experimental Researches on Serumtherapy in Tuberculosis. The following is a summary of it: In the present state of the science, it is not unreasonable to suppose that Behring's law will eventually be applied also to the case of tuberculous infection, it being known that the high toxic power inherent in the protoplasm of the specific bacilli has a very important part in this infection. In the twofold condition created by the present knowledge on tuberculosis, of the almost impossible artificial immunisation of susceptible animals, and not having in mammals a single species endowed with complete natural immunity, the most that can be done in our trials of serumtherapy is to elevate it as highly as possible in the species least susceptible to the virus and the specific poison. In the sheep it is possible to saturate the system with dead bacillary substance, perfect tolerance also existing in the direct immersion into the blood of repeated and increasing doses from 3 to 7 milligrammes for every kilogramme of weight of the animal. The tolerance for the injections of living bacillary substance is undoubtedly less, which, although they do not generally render the sheep tuberculous, nevertheless provoke, through the inefficient reactive conditions, the rapid disappearance of the virus from the organism, and this in the less vigorous and not altogether healthy subjects may in their symptomatic and anatomical complex signify a serious disorder of the general health. The physiological action of the serums of tuberculated sheep is remarkably different in guinea-pigs and rabbits. Thus while the guinea-pig tolerates without appreciable disturbance even 2 cm. per cent. of serum injected at one time into the peritoneum, much smaller doses produce the death of the healthy rabbit through very acute hæmoglobinuria, and 0.2 cm. per cent. is sufficient to kill, by the same malady, the tuberculous rabbit. Such dissolving properties on the red corpuscles of the rabbit are exhausted in time, so that in bleeding a sheep ten months after the last injection a serum is obtained completely inactive. The mixture *in vitro* of the active serum with the tuberculous virus in the proportion of not less than 4 to 1, weakened its activity, causing the death of the guinea-pig sensibly later than that of the control animals. On the contrary, the mixture in the body of the guinea-pig, that is injecting into the peritoneum an abundant quantity of the serum before the injection of the virus, had caused a more rapid production of the experimental disease. The serum in question has shown no positive prophylactic or curative efficacy against the experimental tuberculosis of the guinea-pig. However, under its influence a certain slackening of the disease process was observed, through which the guinea-pigs survived for a long time the control animals, and, coinciding with this, there was a significant modification of the anatomical lesions. This modification consists in an enormous enlargement of the liver and spleen, due in the latter to hyperplasia of the follicles and the pulp, in the former to a classic form of hypertrophic cirrhosis, with grey tubercles, visible almost exclusively in the portal spaces; to which is added less extended caseation of the glands, with tendency to clottation of the surrounding tissues, made especially by the epithelioid cells; no sign of caseation in the inflammatory foci of the lungs; very few bacilli are generally found. Taking everything into consideration, it appears to the authors that there is a great analogy between the effects of the serum of their sheep and the effects already attributed by Koch to tuberculin, inasmuch as the original poison of the latter, in passing through

the organism of the sheep, is not much modified. Through which, and being still put more on their guard by the effects obtained on rabbits, they do not believe themselves authorized by the simple fact of the slackening of the disease process to try the action of their serum on man. For them, then, the problem of its applicability, or at least of Behring's law in the case of tuberculous infection, is still *sub judice*, and with the work done up to now they have only the pretension to have shown a more clear light as to the best and most promising way to the final examination of this very intricate question.

Professor MAZZONI read a paper on Thirty-six Cases of Laparotomy for Tuberculous Peritonitis. He had the opportunity of performing laparotomy in thirty-five cases of tuberculous peritonitis, with thirty-three cures. In two cases he had repeated the operation eight and sixteen months after. The operation was performed once for intestinal tuberculosis, once for tuberculosis of the retroperitoneal glands; seven times there was tuberculosis of the uterine appendages, eight times pleuro-pulmonary tuberculosis, and sixteen times primary tuberculosis. Of those operated upon, two died seven and thirteen months afterwards, one after resection of a tuberculous knee, performed in another hospital. The other patients were living and in good health. He was content as a rule with opening the abdomen, and drying the liquid, without producing traumatism, which he considered superfluous and sometimes dangerous. Anatomically and microscopically the form was that of diffuse tuberculosis, with very numerous typical tubercles. In the two cases in which he had operated twice, one for tuberculosis of the line of incision, the other for abdominal hernia, he observed alterations well worthy of notice. The greater number of the tubercles had disappeared, the remainder were lessened, pedunculated with filiform peduncles, and with little nodules varying in size and form (round, pear-shaped); the adhesions had become thinner or were changed into filaments between the intestines and the various abdominal organs, the tubercles were projecting in the membranes. Microscopically the alterations produced by the operation were as follows: A phlogistic exudation had taken place around the tuberculous tissue, the consequence of the rich vascularisation non-existent before the laparotomy. This was demonstrated in the peripheral part of the nodules, constituted by hyaline reticulum, in whose meshes leucocytes were observed. Of the tuberculous nodules some disappeared, being replaced by a richly vascularised connective tissue, others by a process of cystic degeneration (vacuolisation of the tubercle). This may be held as the effect of a serious infiltration between the tuberculous elements, whence the formation of little cysts, which uniting through the progressive atrophy of the elements produced the cysts which completely substituted the primitive tuberculous nodules. The reading of the paper was followed by a long discussion, in which Professors TRICOMI, DURANTE, POSTEMPSKI, CRECHERELLI, and others took part.

IRISH POOR-LAW MEDICAL OFFICERS.

MR. GERALD BALFOUR, Chief Secretary for Ireland, received last week a deputation from the Irish Medical Association with regard to reform in the administration of medical relief in Ireland. The need for legislative provision for the retirement on pension of Irish Poor-law medical officers was urged strongly upon the attention of the Chief Secretary, and examples of the injustice done under the present system both to the poor and to the medical officers—whose salaries are quite insufficient to enable them to make provision for old age—were given. The necessity for reform in the workhouse infirmaries was also pointed out, the buildings and nursing arrangements considered adequate half a century ago being inconsistent with the health and comfort of the sick, and even with common decency. The abuses and shortcomings of the nursing system were dwelt upon, and it was suggested that Boards of Guardians should be empowered to borrow money for indispensable structural improvements. It was also urged that a Royal Commission should be appointed to investigate the present working of the Poor-law system in Ireland. The Chief Secretary gave the deputation the most

patient hearing and promised to give his most careful consideration to the whole subject.

We offer our congratulations to our brethren in the sister country on the success that has thus far attended their efforts to ameliorate the condition of the Irish pauper, and especially we have in mind Dr. Moorhead, to whose courageous and outspoken words this result is mainly due. If we take some credit to ourselves for having aroused public attention to the question as one result of our special commission we feel sure that our brethren will not grudge us this sense of satisfaction.

OPENING OF THE WINTER SESSION:

BELFAST ROYAL HOSPITAL.

THE winter session of clinical teaching at the Royal Hospital was opened on October 31st, when there was a large muster of students. Nearly all the members of the medical and surgical staff were present. The opening address was delivered by Dr. Mitchell, one of the assistant surgeons, who chose for his topic, "Your Profession, and your Preparation for it." He welcomed the students to the renewal of their clinical studies, and was pleased to see present a considerable number of female students, for whom he believed there was ample room, both at home and in foreign lands. If any of those present had chosen their life-work without any clear idea of what it involved, or any proof of their fitness for it, he urged them at once to review their position, and, if necessary, drop out of the ranks, instead of developing into the well-known "chronic" medical student, and making a failure both of their examinations and their lives. For those whose decision was definitely taken, he urged a broader training than simply that of the medical curriculum. Society expected general culture from medical men, and was justly disappointed if it could discern no tangible fruit of their academic training. Among subjects of general interest, the history of their own country and their own times should occupy a prominent place. In coming from college to hospital for the first time, they should always bear in mind the distinction between plaster casts and dead specimens in the college museums and laboratories, and the highly sensitive human beings who constituted the material for clinical instruction. Their teachers, with every desire to afford the most ample opportunities to students, could not ignore the feelings of patients. The lecturer urged the vast importance of cultivating habits of thorough and systematic observation, on which so much of their after-success would depend. Finally, Dr. Mitchell urged his hearers not to commit the common error of devoting undue attention to rare diseases and striking operations, but to study patiently the more common affections which would constitute the bulk of their work in their future professional life. The address was listened to with much attention, and was warmly applauded at the close.

The staff of the Royal Hospital has been strengthened since last session by the election of Dr. Lorrain Smith as Pathologist to the institution. A new dead-house, pathological laboratory, and lecture-room are about to be erected at the hospital, and it is expected that the facilities for the practical study of pathology will then be ample.

ST. MUNGO'S COLLEGE, GLASGOW.

The opening address at St. Mungo's College was given by Mr. Francis H. Napier, Ophthalmic Surgeon to the Royal Infirmary, Glasgow, who chose for his subject *The Senses: their Use and Cultivation*. In the course of an interesting review of the subject, Mr. Napier referred especially to the wonderful extent to which certain senses had been cultivated in persons deprived of one or more, instancing in particular the cases of Laura Bridgman, who was blind and deaf, and had nearly lost the senses of smell and taste, yet learnt to read and write and communicate with others, and to the case of Helen Keller, who was deaf and blind, yet, at the age of 7, learnt with extraordinary rapidity to read, to write, and to speak. The education of both these girls was achieved through the sense of touch alone. Mr. Napier then proceeded to discuss the extraordinary perfection to which this sense might be brought in the blind, and in dealing with this part of the subject he referred briefly to the "un-

recognized sense" which the blind seemed to develop. "I have," he said, "personally no doubt—no one who has much to do with the blind can fail to recognise—that they possess a sense which is either absent or lying dormant in the sighted. A blind man who has been properly educated will walk along a crowded street, cross roads, and run up and down staircases with the greatest facility. I have seen dozens of blind men skating together and never coming into collision, which is more than can be said for their sighted brethren. A blind man when opposite an object can perceive whether it be tall or short, slender or bulky; he can detect a solitary object or a continuous fence. Mr. Hanks Levy says he can do all this and more; when walking along a street, he can distinguish shops from private houses, and even point out the doors and windows. He says that darkness makes no difference to him, but that a fog dulls his powers, that he seems to perceive objects through the skin of the face, and to have the impressions immediately transmitted to the brain. Covering his face with a thick veil destroys the sense altogether. He calls this unrecognized sense by the name of 'facial perception.'" Having given these and other examples of the unusual degree to which certain senses, and in particular the sense of touch, could be developed by education, Mr. Napier went on to impress on the students the importance of educating all their senses, but especially the sense of touch. At first the effort to make observations by sight and touch, which were at once comprehensive and complete, was an effort, but gradually it became almost unconscious. Mr. Napier discussed also the mental basis of sensation, and in bringing his address to a close he insisted that it was not sufficient for the brain to be a simple storehouse of impulses received through the senses—it must also be educated in order to give to these sensations their proper proportion and significance.

WELL-VACCINATED LOCALITIES.

MR. ALEX. WHEELER (Darlington) writes: Referring to your table appended to my letter in the *BRITISH MEDICAL JOURNAL* of October 19th, I would like to point out that in this table the town of Sheffield, vaccinated as much as it is possible, was afflicted with the small-pox so that 714 persons died of it, and that the city of Birmingham comes next, with equally well-vaccinated population and 211 small-pox deaths, and that Leicester has 8 small-pox deaths, all the 8 deaths being before 1884, and in the period when Leicester was vaccinating as much almost as the other towns. And since she has left off vaccinating she has only had a few units of small-pox deaths, while Birmingham has had a very large number.

Sheffield had almost all of these hundreds of small-pox deaths in the most insalubrious and evil-conditioned part of the city, and she has been spending money to improve these conditions to such an amount that it is no wonder that the small-pox deaths have been but few in the last epidemic. But Birmingham has still an immense amount of lee-way to make up in this matter of improved conditions, and she has been suffering to such an extent as to prove beyond all question that her maximum vaccination condition is of no use at all against the small-pox. In Sheffield the largest awards for Government vaccination were in the very quarters where the most small-pox abounded; and the private vaccination (so much derided as a protection) was most abundant in those parts of the borough that were most free from the small-pox.

Indeed, that old saying of the Austrians, that small-pox is a "beggar's disease," has been proved to be very near to the facts in the last epidemic. For it has been the low parts, the lodging-places of tramps, the poorly-fed unemployed—in a word, the badly-conditioned—who have gone to the small-pox hospital in the largest numbers.

Thus is a lesson of the plainest import spoken to us by the facts going on under our eyes, that if we will allow the existence of fever dens we must have small-pox, but that if we will clear fever dens away we shall have none, or nothing to cause the least alarm or danger to the public health.

Good, bad or indifferent vaccination has nothing to do with the prevalence of small-pox, and it would be proved to have nothing at all to do with the fatality either if we were to execute a most rigid examination of the vaccination register for all the confluent cases of small-pox.

Mr. Wheeler's letter gives us an opportunity of meeting an antivaccination argument on its own ground entirely—one that is seldom granted, by reason of the side issues so often raised. First, as regards the large number of small-pox deaths of late in Birmingham, we may state that in the recent epidemic there were in this admittedly "well-vaccinated population" only two fewer deaths in the unvaccinated minority (75) than in the major portion of the (well-vaccinated) community. Now, if we only allow 80 out of each 100 of population to have been vaccinated, then the 75 deaths in unvaccinated persons should have been not quite 8. On the other hand, had the vaccinated nine-tenths of the population suffered in the same proportion as the unvaccinated we should have seen, not 77, but 675 deaths amongst them. In respect of the mortality-rates in the two classes of sufferers, the epidemic of last year showed that, whereas there were in each 1,000 of vaccinated patients 44 deaths, there were no fewer than 335 in each 1,000 of unvaccinated patients. We need say no more under this head.

On the subject of insanitary conditions having had a preponderating influence on small-pox epidemicity in both Birmingham and Sheffield, we propose to look at the matter in each place separately. First, as to Birmingham, the published data enable us to contrast sanitation and small-pox in only one special particular, namely, on the score of the means at hand for the storage and removal of excremental filth. Dr. Hill has drawn attention to the persistence of the foul ashpit and other forms of privies in the city, all of the nineteen districts into which it is divided having these abominations in greater or less degree. All these nineteen districts had also small-pox attacks in greater or less degree. Proceeding to record for each and every district the number of houses—populations not being accessible—the number of privies, and the small-pox attacks in 1894; and then the rate per 1,000 houses of both privies and small-pox attacks; and going on further to look upon the rates for the whole city in each case (privies and small-pox) as 100, we have, in addition, set down in the table herewith what is the relation of privy and small-pox prevalence in each district to the entire city.

BIRMINGHAM: 1894.

District.	Houses.	Privies.	Small-pox Cases.	Rates per 1,000 Houses.		District Rates—City Rates being 100.	
				Privies.	Small-pox Cases.	Privies.	Small-pox Cases.

* Containing City Small-pox Hospital.
† Adjacent to City Small-pox Hospital.

We think the table very clearly indicates that privy nuisance and small-pox prevalence were nowise related, but that the one preponderating factor in determining the rate of small-pox incidence was proximity to the City Small-pox Hospital. And we may fairly claim that where the privy nuisance abounded, there too did accompanying insanitation abound. Indeed, Dr. Hill does not hesitate in his report to

speak of enteric fever and privy conditions as being in close relation. We now pass on to Sheffield.

In Sheffield there was one factor in the nature of "sanitation" which had a determining influence on the prevalence of small-pox in one and another portion of the borough, and that factor was overcrowding. Whether on area as regards dwellings, or in houses as regards population, it will readily be conceded that with a disease of the high infectivity of small-pox, as with diphtheria or measles, there was likely to be most small-pox where there was most opportunity for mingling of sick and healthy, and especially where the housing of the people was of such sort as to necessarily bring many persons in close touch with the unisolated sick. To judge of the non-effect of sanitary conditions on small-pox prevalence, we have only to look at the data supplied by comparison of the rates of mortality from that disease and others in Sheffield. So we set out the facts in the second table herewith, choosing Sir George Buchanan's figures in his introduction to Dr. Barry's classic report on the small-pox epidemic of 1887-88. For the purposes of this table the epidemicity of the several diseases in the earlier period has been regarded as 100 in each instance, so as to form some common basis of just comparison; so that the fall in the table is always from 100, as also the rise shown.

Table showing Decrease and Increase of Rates of Mortality from certain specified Diseases in Sheffield during the later of Two Comparative Ten Yearly Periods—the Rates in the earlier period being for each Disease at each Age-group regarded as 100.

Diseases.	All Ages.	Under 10 years.	Over 10 years.
Measles ...	78	78	60
Scarlatina ...	78	72½	75
Whooping Cough ...	93	93	NB
Diphtheria ...	72	72	77
Diphtheria ...	39	33	50
"Fever" ...	34	26½	39
Small-pox (10 years)	28	10	134

The table speaks for itself. We may regard, for the sake of a brief comment, "fever" as being the one disease of all others affected by insanitary conditions. This being so, we see that whereas the 100 rate has become only 34, at all ages, small-pox has fallen still further to 28. But in the case of "fever," the fall is distributed over both children and adults. Not so with small-pox. The fall is wholly in the first ten years of life. Nay, further, the fall is so enormous in the first decennium of life, that it has more, much more, than counterbalanced the large increase (the only increase in the table) in the later years of life. It is in the first ten years of life that primary vaccination exerts its chief influence of protectiveness against small-pox, and it is in this age period that small-pox has shown its chief, its only fall; and in this respect it is unique among the diseases in the table.

SMALL-POX AND VACCINATION IN WOLVERHAMPTON IN 1894—XXIII.

Dr. HENRY MALET, the health officer of Wolverhampton, in his annual report for 1894, has placed on record the facts concerning the limited outbreak of small-pox which occurred in that town in the three concluding quarters of the year, the cases totalling to 67, of which 62 are tabulated as occurring in houses in the borough, some few cropping up in the workhouse, etc. With the exception of these latter and 2 dubious attacks in the town, all the patients were isolated in hospital. But the isolation arrangements were not at all what could have been desired when the disease broke out in April of last year, and as one result of isolating the malady on the same site as scarlet fever patients, two of the latter caught the infection of small-pox, and in one of these instances the disease was conveyed to another member of the patient's family.

Few as were the cases, they still furnish evidence of the good influence of vaccination and revaccination. Treating of the houses in which the attacks were heard of, and dividing the town into two districts, Dr. Malet arrives at the following data for the whole town: In the invaded houses were

residing 272 persons, divisible into 241 vaccinated individuals, with 54 cases, 3 deaths, and 9 severe attacks; 21 unvaccinated persons, with 8 attacks, 2 deaths, and 8 severe attacks; and 10 revaccinated persons, among whom no case arose. Among the vaccinated the attacks and deaths were 22 and under 2 per cent.; but among the unvaccinated 33 and 9 respectively. Among the revaccinated, total immunity from even attack. At ages under ten years the rates of attack in the two classes were, vaccinated 8.5, unvaccinated 33.3; and at ages over 10 years the attack rates were 26 and 66.6 respectively. Not only so, but with the inclusion of 13 revaccinated persons attached to the small-pox hospital staff who escaped infection, we see that all the 23 revaccinated persons exposed to infection wholly escaped the disease. In the town the proportion of deaths among the unvaccinated community exposed to infection was nearly 8 times that of the vaccinated portion; and the proportion of severe attacks was 13 times as high. In regard to the power of propagation of the infective properties of small-pox, Dr. Malet states that any two of the severer unvaccinated cases gave off more infective material than all the 54 vaccinated cases together.

Here, then, we see complete immunity from the disease of all the revaccinated persons coming in contact with the morbid, and the protective quality of primary vaccination in the first ten years of life strikingly exemplified. But Dr. Malet goes on to state very pertinently that if the whole of the vaccinated and the unvaccinated community had each been a separate social organisation, we should have seen a very different state of things from that now in evidence. Indeed we should. As society is to-day constituted it is the vaccinated members who to a large extent save the unvaccinated portion from the fearful ravages which but for the protected element would be seen among the growing numbers of our population who have not been under the surgeon's vaccinating lancet. It is in proportion as the unvaccinated element is found in the invaded households that small-pox obtains a greater or feebler hold on the inmates.

THE THREATENING EPIDEMIC OF INFLUENZA.

[SPECIAL REPORTS TO THE BRITISH MEDICAL JOURNAL.]

Deaths in London and West Ham.—Increased Prevalence in Surrey and the West Riding of Yorkshire.—Cases in Norwich, Manchester, Liverpool, and Halifax.

IN view of the indications that influenza may be about to become epidemic once more this winter in London, we have thought it well to make some inquiries as to the existence of the disease in other parts of the country, and we are indebted to the medical officers of health of many of the counties and county boroughs for some interesting information.

First, however, we have to record an increase in the number of deaths from influenza in London. In the week ending October 19th the number was 8, in the succeeding week it was 4, but in the week ending November 2nd the number had risen to 7; in the week ending November 9th, 10 deaths in London were attributed to influenza. Of these, 5 occurred in North London (1 in Marylebone, 2 in Islington, and 2 in Hackney), 1 in Shoreditch, and 4 in South London (1 in Bermondsey, 1 in Putney, and 2 in Peckham).

The mortality from diseases of the respiratory organs has during the past few weeks shown a very rapid increase. During the past fortnight the mortality in London from these diseases has nearly doubled; for while the deaths referred to them were 235 during the week ending October 26th, they rose to 366 in the following week, and to 447 during the week ending Saturday last, November 9th. The latter number, however, exceeds by only 55 the average number in the corresponding periods of the ten preceding years, the mortality for many weeks previously having been considerably below the average; indeed, from the end of July last, the weekly deaths from respiratory diseases have been continuously below the average. With regard to the deaths from these diseases last week, it appears that the mortality from pneumonia showed the largest excess, the deaths attributed to this cause being 145, and 32 above the average; while the 220 fatal cases of bronchitis were 25 above the average number.

Last week 3 deaths from influenza were registered in West Ham, and Dr. Sanders, the medical officer of health, informs

us that the facts which have come to his knowledge point to an epidemic. In Surrey it would appear that the disease which existed in nearly all parts of the county in March and April declined rapidly in May, and had almost disappeared in July. Dr. Seaton informs us that it was reported in four districts in August, in the same number in September, and in five in October. The returns for one district, Frimley, for that month show a distinct recrudescence, the disease being reported as "very prevalent." Dr. Philpot, medical officer of health for Croydon, informs us that though a few sporadic cases have been noted there are as yet no indications of a fresh epidemic in that borough, but in all preceding epidemics the prevalence in Croydon has commenced ten days or a fortnight after the disease had become established in London. He states that the first cases in previous epidemics have always been among business men going daily to London, and adds that the suburban trains give ample opportunities for spreading the infection.

The medical officer of health for Norwich informs us that there are distinct indications of an epidemic, but it is not as yet widely spread, nor are the cases pronounced. It will be remembered that certain parts of East Anglia were among the earliest districts attacked in the first epidemic of the present visitation.

There was 1 death from influenza in Manchester last week, and Dr. Nevin, the medical officer of health, informs us that deaths from respiratory diseases have been above the average during the last fortnight. The same is true of Liverpool, Dr. Hope reporting 1 death and a considerable increase in the death-rate from pneumonia and other pulmonary diseases. On the other hand Dr. O. E. Paget, medical officer of health for Salford, states that there are at present no indications that a fresh epidemic of influenza is commencing in that borough; and Dr. Sidney Marsden is able to speak in like reassuring terms of Birkenhead. Dr. Whitelegge, in his summary for the month of October, states that the increase in influenza and pneumonia in the West Riding of Yorkshire noted in September was continued throughout October, cases of influenza having occurred in twenty-nine districts, as compared with fifteen in the previous month and ten in August. Dr. Ainley, medical officer of health for Halifax, has informed us that several cases of influenza have occurred there lately, with at least one death. In Leeds Dr. Spottiswoode Cameron states that there is nothing like an outbreak, and that no deaths from the disease have been registered this quarter, though there were 7 in the last quarter and 35 in the preceding quarter (second quarter of 1895). In Huddersfield Dr. J. R. Kaye states that there have been only a few sporadic cases, and we learn from Dr. Evans that there are no indications of an approaching epidemic in Bradford. In Hull Dr. J. Wright Mason has heard of a few cases in which the nervous symptoms were most marked, but there is no epidemic. In Lancashire, outside of Manchester and Liverpool, there do not appear to be any indications of an epidemic, though we learn of a few cases in Preston, Oldham, and Burnley, while Bolton is at present free. From Northumberland we learn that a mild type of influenza is prevalent in one or two districts only.

From Gateshead, Sunderland, Portsmouth, and Cardiff we learn that there is no reason to suppose that an epidemic is threatening, while Dr. H. M. Williams, M.O.H. Plymouth, states that it is now nearly four months since a death was registered there from influenza, the longest period of immunity from fatal cases since March, 1891. The Midlands, also, so far as our information extends, appear to be almost or quite free. One death, Dr. Alfred Hill informs us, occurred in Birmingham last week. Dr. Henry Neale reports a prevalence of severe catarrh and a good deal of pneumonia in Wolverhampton, but no typical cases of influenza; while Leicester and the county of Derby are believed to be quite free from the disease.

The most significant fact brought to notice, beyond the unmistakable recrudescence of the disease in London and West Ham, is that in the only two large districts from which we have been furnished with returns for a considerable period—that is, in Surrey and in the West Riding of Yorkshire—the disease, though not prevailing as an epidemic, has not, it would seem, been absent for months past, and that influenza would appear to have become endemic in these districts.

THE SANITARY CONDITION OF WINDSOR.

THE report by Mr. Bailey Denton on the sanitary condition of Windsor, which we published on October 26th, seems to have given rise to a certain amount of local irritation—as, indeed, it might well do.

Those whose negligence was so openly demonstrated were bound to do something, and, instead of undertaking the arduous but useful duty of reformation, they appear to have embarked on the easier course of abusing our witness and accusing him of anisms. But the facts remain, and from information derived from other sources we gather that they are likely so to do. What is much wanted in Windsor is some real municipal spirit. If it is true, as we are informed, that while the people who live in the insanitary districts do not dare, the people who live near them do not care to raise any protest, or to memorialise the Local Government Board again, the matter becomes one of considerable urgency, for it is unlikely in the extreme that insanitary areas, such as were described in the report of Mr. Bailey Denton, can go on for long without acting as foci of disease and breeding spots for epidemics. It is no use pointing to the death rate as proof of foulness. A crude death-rate standing by itself is but poor evidence one way or another of the healthiness of any place. The real question is, Have the recommendations given by the expert inspectors sent down by the Local Government Board been carried out? What has happened to the houses which they condemned? where do the slum tenements still stand? what is being done with the town refuse? where is there any sign of the slum areas being dealt with under the Housing of the Working Classes Act? and, lastly, what has become of the promises, made long ago, that if the Local Government Board would send down its inspectors their recommendations should be carried out? Windsor might be made into a charming place of residence, but if that must be made safe from a sanitary point of view; and however selfish people may be and however confident they may feel that they can live their own lives independent of all men, it is a fact to which the inhabitants of Windsor will probably some day receive a rude awakening that the existence of slum areas in their midst is a sanitary danger.

ASSOCIATION INTELLIGENCE.

ELECTION OF MEMBERS.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, *General Secretary.*

LIBRARY OF THE BRITISH MEDICAL ASSOCIATION.

MEMBERS are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the members in commodious apartments, at the offices of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 2 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

LANCASHIRE AND CHESHIRE BRANCH.—A special general meeting of this Branch will be held in the Memorial Hall, Albert Square, Manchester, on Friday, November 22nd, at 4 P.M. Agenda.—Report of the Council of the Branch on the New Medical Services Registration Bill as drafted by a subcommittee of the Parliamentary Bills Committee. Report of the committee of the Branch, appointed on March 26th, 1896, "to watch the progress of, and to oppose any proposed legislation for the registration of midwives." Mr. H. B. FROST will move and Dr. G. H. BROADBENT will second: "That a vigilance committee of members of the Branch be at once elected, with power to add to their number, to

watch the progress of any legislation for the registration of unqualified persons to practise medicine, surgery, or midwifery without the supervision of those already registered under the Medical Act." Mr. W. WHITEHEAD will "call attention to the importance of modifying the management of the Association so as to give the members in general meeting the control of the policy of the Association," and he "will move a resolution." Mr. COLIN CAMPBELL will move and Dr. J. B. Brierley will second: "That this Branch contribute £20 to the fund which is being raised to repay Dr. R. K. Kenton his expenses incurred in defeating the first and second Midwives Registration Bills." Arrangements will be made for a dinner to be held at the Albion Hotel immediately after the meeting if at least thirty gentlemen notify their intention to be present to the Secretary before November 15th. Tickets (not included) 5s. each. Applicants for membership should at once communicate with the Secretary, JAMES BARR, M.D., Honorary Secretary, 12, Rodney Street, Liverpool.

METROPOLITAN COUNTRIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.—The next meeting will be held at the Town Hall, Walthamstow, on Thursday, November 21st, at 8.30 P.M. The chair will be taken by Dr. DALY, Vice-President of the district. Mr. Bowby will read a paper on Diseases of the Throat and Nose in Childhood. Visitors will be cordially welcomed.—HERBERT E. POWELL, Honorary Secretary, Glenarm House, Upper Clapton.

SOUTHERN BRANCH: SOUTH-EAST HANTS DISTRICT.—At the Medical Library, 5, Pembroke Road, Portsmouth, on Tuesday, November 19th, at 9 P.M., ordinary meeting. Gentlemen proposing to present any communication, case, or specimen are requested to inform the Honorary Secretary. On Friday, November 22nd, at 4 P.M., special meeting. Agenda: To consider the notices of motion by Dr. PEARCE and Mr. LOND, postponed from the ordinary meeting of November 1st, and published in the BRITISH MEDICAL JOURNAL of October 26th, at p. 1660.—C. G. CLAREMONT, Honorary Secretary, 57, Elm Grove, Southsea.

SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT.—The next meeting will be held at the Hospital, Hastings, on Thursday, November 26th, at 8.30 P.M. Dr. ALLEN (President of South-Eastern Branch) in the chair. Dinner at 6.30 at the Grand Hotel. Charge, 6s.; exclusive of wine. Professor CORFIELD (London) will give an address on The Water Supply of Towns. Mr. PEPILLON and Dr. Redmayne will show Ophthalmic Cases. Dr. WILLS will read notes of a Case of Graves's Disease treated with Suprarenal Tabloids. Mr. LAMMIMAN will speak on the Connection between Disease of the Uterus and Operations upon the Female Pelvic Vessels and Effusion into the Pleura.—J. W. BATHURST, Honorary Secretary, Bank House, Grand Parade, St. Leonard's.

SOUTH-EASTERN BRANCH: EAST KENT DISTRICT.—The next meeting of this District will be held at the Kent and Canterbury Hospital on November 21st, at 3 P.M. Mr. ROBERT HICKS, of Ramsgate, in the chair. Tea and coffee will be served in the Board Room of the hospital after the meeting. All members of the South Eastern Branch are entitled to attend these meetings and to introduce professional friends. Agenda.—Dr. GOGARTY: Pleuritic Effusion; Aspiration; Rare Cases. Dr. EDMONDSON: Poisoning by Boracic Acid in Milk. Dr. TYNNE: Appendicitis.—THOS. F. RAVEN, Honorary District Secretary, Barfield House, Broadstairs.

STAFFORDSHIRE BRANCH.—The first general meeting of the session will be held at the North Stafford Hotel, Stoke-on-Trent, on Thursday, November 28th. The president, Dr. GEO. REID, will take the chair at 4 P.M. Agenda: Exhibition of Pathological Specimens. Living Cases, New Instruments, etc. Papers:—Dr. McARDLE: Pseudo-bulbar Paralysis. Dr. HATTON: Notes on a case of Nephro-lithotomy. Mr. SPENCER: The treatment of Stricture of the Oesophagus by means of Expanding Bougies. Mr. A. V. GRIFFITHS: A case of inversion of the Uterus. There will be a dinner (6s., exclusive of wine) at 6 P.M., after the meeting.—F. MITCHELL BLUMER, Honorary Secretary, Stafford.

SOUTH-EASTERN BRANCH: WEST KENT DISTRICT.

THE first meeting of the thirty-ninth session of this District was held at St. Bartholomew's Hospital, Rochester, on October 18th, at 4 P.M. Mr. J. HOLROYDE in the chair. Eleven members were present.

Confirmation of Minutes.—The minutes of the last meeting were read and confirmed.

NEXT MEETING.—It was decided that the next meeting should be held in March, 1896, at Maidstone; and it was proposed by Mr. HALLOWES, and seconded by Dr. J. V. BELL, that Dr. F. Pritchard Davies, of Barming Heath, be invited to preside. This was carried unanimously. It was proposed by Dr. J. V. BELL that the dinner held after each meeting should be held only once a year. This was supported by Mr. HALLOWES and the CHAIRMAN, who proposed that the question be raised again at the meeting at Maidstone.

Communications.—Mr. OFFENSHAW read a paper on the Symptoms, Pathology, and Treatment of Congenital Dislocation of the Hip-Joint, in which he dwelt on the disappointing results obtained by mechanical contrivances, and advocated operation by exposing the joint, clearing out the glenoid cavity, and drawing the head of the femur into it, if necessary dividing the adductor muscles, and retaining the joint in this

position for one month. Mr. Openshaw stated that he had met with very favourable results. The paper was discussed by Drs. BELL and BRUNYATN, and Messrs. HALLOWES, HUGH SMITH, BRYDEN, and the CHAIRMAN.—Mr. HUGH SMITH read notes of a case of Graves's Disease and Myxœdema after Treatment with Thyroid Gland. The patient had been shown before treatment at the meeting in Maidstone in March, 1895, and then exhibited well-marked symptoms of myxœdema. Under six months' treatment with thyroid extract a marked improvement took place. Mr. Smith drew attention to the fact that several cases of exophthalmic goitre had derived benefit from thyroid extract.

Proprietary Remedies.—Dr. GROUND read a paper on The Position of the Government with regard to Proprietary Remedies. He pointed out the fictitious value given to proprietary remedies, all of which consisted of simple and well-known remedies (aloes appearing to be first favourite), or powerful poisons, which practically rendered the Sale of Poisons Act abortive. He instanced the chlorodyne preparations, which contained large quantities of morphine and chloroform, and yet could be purchased without any difficulty by the public because, being proprietary remedies, they were specially exempted from the provisions of the Sale of Poisons Act. He also showed that under the existing regulations with regard to proprietary medicines a great public injury was done, and the people left at the mercy of the advertising and unscrupulous quack; and that this country was far behind France in this respect, where the sale of secret remedies was forbidden, and Germany and Italy, where the composition of all proprietary remedies must be printed on the labels or wrappers of the box or vessel containing it, and sold only by chemists. The remedies suggested were: (1) Every proprietary medicine should bear upon each box, bottle, or packet in which it was sold a conspicuous label stating its composition; and (2) licence to sell patent medicine should be withheld from all persons having no real knowledge of the nature and action of drugs.—It was suggested by the CHAIRMAN and Dr. BELL that the attention of the Branch might be drawn to this question, but owing to want of time it was not discussed.

Dinner.—After a vote of thanks to the hospital authorities for the use of the Board Room, four members (the Chairman, Mr. Openshaw, Dr. Bell, and the Honorary Secretary) dined together at the Bull Hotel.

PERTHSHIRE BRANCH.

The annual meeting of the Branch was held at Perth on November 1st, Dr. LEIGH HUNT, President, in the chair. Twelve members were present, and the SECRETARY intimated apologies from several unable to attend.

Confirmation of Minutes.—The minutes of last meeting were read, approved, and signed by the President.

New Members.—The following new members were duly elected: John Anderson, M.B., C.M., Pitlochrie; R. M. Clark, M.B., O.M., Royal Infirmary, Perth; Alexander MacEwen, M.B., O.M., Crieff; and David Melville, M.B., C.M., Bridge of Earn.

Election of Office Bearers.—The office bearers for the ensuing year were elected as follows:—President: Dr. Leigh Hunt, Perth; Vice-President: Dr. Macmillan, Stanley; Secretary: Dr. Urquhart, Perth; Treasurer: Dr. A. G. A. Campbell, Perth; Council: Drs. A. Thom, G. M. Robertson, Niven, Mackay, and Paton.

Report of Council.—The report of the Council was read, showing an increase of two members since the last annual meeting, and it was resolved to hold a special meeting for scientific purposes in the Royal Infirmary in January next.

Club Practice.—The SECRETARY submitted a circular letter as to club practice and other matters affecting the profession. The meeting passed the following resolution:

That this Branch expresses no opinion further than that recorded in their minute of November 2nd, 1894; and that it be now remitted to the Secretary to ascertain the opinion of members as to the propriety of holding a joint meeting in Perth, and to obtain guarantees for the necessary expenses of such a meeting; and, further, that it be remitted to the Council to arrange the details connected with any such meeting, or to name representatives to attend if it be held elsewhere than at Perth.

Treasurer's Report.—The TREASURER submitted his report showing a balance of £11 10s. 10½d. in his hands.

President's Address.—The PRESIDENT delivered an address on a Case of Puerperal Septicæmia, followed by Pelvic Peritonitis and Subinvolution ending in Recovery.

Communications.—Dr. FERGUSON described a case of Malformation of both Ears, and submitted photographs of the same, with remarks by Dr. Downie, of Glasgow.

Dinner.—The members afterwards dined together.

BORDER COUNTIES BRANCH.

The autumn meeting of this Branch was held at Kendal on October 25th. Dr. SMITH (Dumfries) presided, and about thirty members and visitors were present.

New Members.—The following were elected members of the Branch: P. F. Sturridge and A. J. McCallum (Kendal), J. C. Carden and J. H. Seagrave (Milnthorpe), A. J. Newman (Bowness), G. R. Penrose (Burton, Westmorland), J. Kendal (Conistone, Lancashire), W. Wyllie and W. E. Ledgard (Kirkby Lonsdale).

Communications.—Dr. McCALLUM (Kendal) showed a boy who had been cured of unusually severe Epilepsy by the use of enormous doses of bromide of potassium.—Dr. W. R. PARKER (Kendal) showed a Cretin recovering under the use of thyroid extract, and photographs of numerous Cretins before and after treatment.—Dr. W. B. COCKILL (Kendal) described a case of Albuminuria with atrophy of the optic nerve, closely simulating cerebral tumour.—Dr. WALKER (Kirkby Stephen) and Dr. McCALLUM showed a number of microscopic sections of Mammary Tumours.—Dr. P. F. STURRIDGE (Kendal) communicated Notes on the Eyesight of 300 School Children.—Dr. A. J. NEWMAN (Bowness) read a short paper on Obstetric Statistics, a digest of 500 successive cases.—Dr. G. H. SEAGRAVE (Milnthorpe) read a paper on the Hypodermic use of Cocaine in Neuralgias.—Dr. TAYLOR (Kendal) described an instance of Bone-setter's Malpractice.

Dinner.—Twenty members and visitors dined together afterwards, the Kendal members and Dr. Newman being the hosts.—The PRESIDENT, in moving a vote of thanks to the entertainers, made special mention of the energy of Dr. Parker, who had charge of the arrangements for the meeting.—Dr. PARKER, in replying, said he hoped that Kendal or the immediate district would hereafter receive an annual visit from the Branch.

NORTH OF IRELAND BRANCH.

The autumn meeting was held at Belfast on October 31st, 1895.

Confirmation of Minutes.—The minutes of the spring meeting were read and confirmed.

New Members.—The following new members were elected: Dr. Maguire, Dr. Hugh Fisher, Dr. A. A. Ferguson, and Dr. John Eusk, of Belfast; and Dr. Torrens, of Connor, and Dr. Wilson, of Galgorm.

Publication of Proceedings.—It was moved by Dr. GRAY (Armagh), and seconded by Dr. CALWELL:

That it is desirable to have the contributions read at the meeting printed and circulated among the members of the Branch.

In moving this resolution, Dr. Gray referred to the reports of meetings which appear in the JOURNAL, and expressed the opinion that they were not sufficiently full to be of service to those members who had not been present at the meetings. After some discussion, the following was moved as an amendment by Dr. LINDBAY, and seconded by Dr. STACK, and passed by a large majority:

That the Council be instructed to confer with the Council of the Ulster Medical Society with the view of determining whether a joint publication of the proceedings of the two societies is practicable.

President's Address.—Dr. STUART, the President (Ballymena), delivered an instructive and practical address on the Treatment of Purulent Collections in the Pleural Cavity. He gave the notes of several very successful and interesting cases which had been treated by operation by him. When he had concluded, Professor SINCLAIR expressed the pleasure which the members had in listening to an address on a subject of such wide interest and importance, and moved a vote of thanks to Dr. Stuart. This was seconded by Dr. LINDSAY, and passed by acclamation.

Communications.—Dr. DARLING (Lurgan) showed a patient from whom he had Excised the Scapula. He also exhibited

the excised bone, which was the seat of an Enchondroma. Professor SINCLAIR congratulated Dr. Darling on the success of the case and on the fact that this operation was the first of its kind in Ulster.—Dr. MACCORMAC read a paper on Nervous Troubles of Articulation and their Treatment.—Dr. STACK showed a Midwifery Forceps with a new form of Traction Rod. He explained that the idea was to render perfect the action of Nevill's traction rod.—Dr. R. M. FRASER showed a case of Ruptured Ligamentum Patellæ after Treatment. Drs. DARLING and FULLERTON made some remarks on the case, and Dr. FRASER replied.

SPECIAL CORRESPONDENCE.

PARIS.

The New System of Distribution of Patients in the Paris Hospitals.—Examinations for the Internat.—The Alcohol Question in France.

THERE has been a general meeting of the Paris hospital surgeons, at which the following resolution was unanimously passed: "The hospital surgeons claim for the poor sick the absolute right of choosing the surgeon they prefer to treat them. The said surgeons demand that the *circonscriptions hospitalières* be abolished." It was likewise decided at the same meeting to publish with this resolution a copy of the protest presented by the physicians and surgeons of the Paris hospitals to the Minister of Public Instruction in May last against the decree of the Director of the Assistance Publique concerning the hospital reforms approved of by the Prefect of the Seine on April 13th, 1895. The hospital surgeons and physicians expressed the belief that the Director of the Assistance Publique agreed with the views held by the Conseil de Surveillance, and that he was ready to carry out the reforms recommended in the Council's report. They are disagreeably surprised to learn that M. Peyron has changed his mind and adopts the views of the Municipal Council. Professor Lannelongue, member of the Chamber of Deputies for Gers, has explained the matter in all its details to the Prefect of the Seine, who appears inclined to maintain the views of the Municipal Council. Among all the arguments for and against the *circonscription hospitalières* there is a serious one against it. Since this system has been in force certain hospitals are overcrowded, and others are comparatively empty. At the Beaujon Hospital, being in a part of Paris where the inhabitants are all more or less wealthy, there are many beds untenanted. This is not the only hospital which, formerly full, now has wards sparsely filled. The Tenon Hospital is overcrowded. This evil result is of greater importance than the question of preventing hospital surgeons and physicians from satisfying their taste for their medical hobbies; one who has a predilection for liver diseases admitting those lucky sufferers and refusing all others; another pursuing the same policy as regards nervous diseases, and so on, *ad infinitum*. This objection, if it is an objection, exists undeniably; but the practice has a certain advantage, for it facilitates the study of special conditions, and thereby facilitates their cure; and, above all, does not empty one hospital to overcrowd another, which is a terrible indictment against the efficiency of any given hospital administration. The Conseil de Surveillance de l'Assistance Publique has met to discuss the question who is to see the hospital out-patients. M. Peyron, the Director of the Assistance Publique, proposes slightly to modify the new regulation, and allow all members of hospital staffs of ten years standing to give those consultations if they wish. Six members voted that all should have that privilege; five voted with M. Peyron. The Municipal Council and the Prefect of the Seine hold the same views as M. Peyron, who distinctly stated that when the question is again discussed at the Municipal Council, he will oppose the vote passed by the majority of the members of the Conseil de Surveillance de l'Assistance Publique.

Dr. Félix Regnault, in an amusing article in the *Médecine Moderne*, points out the defects in the system of preparing for the competitive examination passed by the candidates for the *internat* (posts of house-physician and house-surgeon in the Paris hospitals). He says the candidates neglect

the hospital, neglect dissecting and operative surgery on the dead body. They read and re-read books impossible for them to master although they take notes and make extracts. The practice of meeting together to treat anatomical and pathological questions by discoursing on them during ten minutes after ten minutes' reflection M. Regnault considers deplorable. The listeners promptly interrupt the candidate when the ten minutes allowed for speaking are past, and then criticize and pull to pieces the lecture. The important point in these rehearsals of the real examination is not to exceed the ten minutes, this being also of vital importance when in presence of the real examiners. M. Regnault desires the examinations to be maintained because they oblige young men to work, but as at present arranged they oblige them to work badly.

The public interest in alcoholism and the questions connected therewith does not decrease; it reaches far and wide throughout France. M. Aiglavie, Professor of the Paris Law Faculty, gave a lecture at Montpellier on the Rectification of Alcohol by the State and the System of State Monopoly he advocates. The lecture hall was crowded. Official notabilities, scientists, and wine growers were present, with a considerable number of ladies.

ST. PETERSBURG.

A "Miraculous" Cure in Moscow.—Proposed Alterations in the Regulations for the M.D. Degree.—A Badge for Qualified Medical Men.—The Superstitious Murder Case in Siberia.—The Cholera Epidemic.

A "MIRACULOUS" cure has recently occurred in Moscow, where it has caused considerable excitement. It is, perhaps, a more than usually interesting instance, and therefore deserving of the permanent record given to it by Professor Kozhevnikov, who gave the details of the case at the last meeting of the Society of Neuro-Pathologists in Moscow. The professor had not had the patient under his treatment, but had seen him more than once both before and after the "cure." The patient, N. D., was a lecturer in the Moscow University. He had suffered from a severe form of sycois menti since June, 1894, for which he underwent treatment at the hands of various specialists—among others, of Professors Kaposi, of Vienna; Schwimmer, of Buda-Pesth; Lassar, of Berlin; Pospélof, of Moscow; and Stukovenko, of Kiev. In April last he returned to Moscow; his chin was then covered with a freely-suppurating eruption. He now sought the advice of a "wise woman," an attendant at the baths, who was in the habit of giving herbs and "simples" to her clients. In this case no such remedy was employed. N. D. was told to meet the woman next morning at 5 o'clock in the Temple of the Saviour, the colossal church on the Moskva river, which has been building all the century and is yet incomplete, in memory of the famous events of 1812. He came as told, and, while he remained a passive onlooker, the woman prayed for three or four minutes; the same thing was repeated that evening and again the following morning. But in the meantime the eruption on N. D.'s face had begun to improve; the discharge ceased, the swelling subsided, and in twenty-four hours scarcely a sign of disease was left. Such are the facts as given by the patient himself and confirmed by Professor Kozhevnikov. The professor, however, adds some important points bearing on the case: The patient is of neurotic temperament; his sister is highly hysterical; he had frequently had boils on both arms, with a marked tendency to symmetry in position; and the sycois itself showed some signs of being, if not of nervous origin, at least under nervous influence. The impressive surroundings under which the "cure" was wrought, and the mysterious cabalistic prayer—which the woman refused to divulge, "lest it should begin to act with the person to whom she told it and cease to act with herself"—are also factors to be remembered in connection with the neurotic and impressionable character of the patient.

Eight Russian Universities—those of Moscow, Kazan, Kharkof, Kiev, Yurief (Dorpat), Tomsk, Warsaw, and Helsingfors—and the Army Medical Academy in St. Petersburg grant medical degrees. Of these degrees there are two—those of *Udhar* and *Doctor Medicinae*. Not very long ago the regulations for obtaining the lower degree were considerably altered, and

It is now proposed to make even more radical changes in the regulations relating to the M.D. degree. The main object of the proposed alterations is to raise the status of the degree. With this end it will no longer be, as now, a so-called "scientific-practical" degree, but a purely "scientific" or "learned" degree. The chief results of this change will be in connection with the extremely complex system of *chairs*, or *caules*, which in Russia determines the official standing of each profession and of every individual in it. These results need not be entered into here. But some other effects are worth noting. One is that fewer men will in future obtain the M.D. degree. Apart from the fact that it will be more difficult to obtain, it will no longer be necessary for certain important appointments. For instance, a *glavnyi vrach* ("chief doctor," in entire control of the hospital, both medically and administratively) of any hospital will not be obliged to hold the M.D. degree, as under the present regulations. This will throw open such appointments to a far larger number of candidates. Another effect will be that under the new regulations only a specialist can become M.D. A candidate for the degree will have to select one of seventeen named specialities, and in this he will undergo a searching examination, as well as in certain subjects of general medicine. As at present, a thesis will have to be presented and publicly defended.

A bye question has arisen in connection with the recent and proposed alterations in medical degrees. Holders of the M.D. degree are entitled to wear a silver badge or medallion on their breasts—a double-headed eagle and two coiled snakes—the whole some 1½ inch in diameter. A *lekár* has no such badge to indicate that he possesses a learned degree. When recently a move was made by the veterinary profession for the right to wear a badge, it was suggested that the same right should be granted to *lekárs*. It was pointed out that it would be scarcely fair (more particularly in a cavalry regiment) for the veterinary surgeon to wear a badge while the surgeon proper had none. It is probable that both will obtain the right to wear one in future.

In July last I sent a short account of the trial of thirteen peasants (mostly, it seems, of the tribe of Votyaks) who murdered, in Central Siberia, a stranger whom they took for "the cholera." Their case has been submitted for consideration to a committee of the following experts: Professor Smirnov, of Kazan University; M. Bogasfski, the head of the Votyak school in Kurlingán, and an ethnologist who has made a special study of the beliefs and customs of the Votyaks; M. Andreff, who has published a work on the same subject; M. Verestchagin, and Drs. Minkévitch, Krusof, and Koshech.

The cholera epidemic is declining everywhere, except in Volhynia. There the figures for the two weeks ending September 23rd and 30th (old style) respectively were 1,418 cases with 608 deaths, and 1,453 cases with 582 deaths. In the same two weeks in the Government of Kiev the figures were 31 cases with 24 deaths, and 28 cases with 13 deaths. Vladivostok is declared to have been free from cholera since September 25th (October 7th); and the Government of Podolia to have been free since September 17th (29th).

ROME.

Reopening of the University of Rome: Address by Professor Celli.
—Professor Maragliano's Serum.

THE inauguration of the scholastic year of the University of Rome took place on November 4th. The Rector, in his statistical statement for the last year, mentioned that the number of medical students was 796, which exceeded by 119 the number of the previous year. The inaugural address was given by Professor Celli, the Director of the School of Experimental Hygiene in Rome, who is also a Radical deputy. His theme was, "The Discouragements and Hopes of Social Hygiene." He described the evils produced in the working classes by insufficient and bad food. The Italian agricultural population lived poorly and with difficulty on maize, chestnuts, and even acorns. He referred to the injuries produced by malaria amongst the agricultural classes, and stated that in Italy they had over 400,000 acres of pestilential rice fields; goitre and cretinism attacked 145,000 peasants. He enumerated the injuries produced by precocious work in mines and

factories; in the first where the children presented a painful affection of the bones; in the second where children under 9 years of age wasted their existence, and where anemic and chlorotic women gave birth to generations of scrofulous and rachitic children. He described the insanitary conditions of the houses of the working classes in the cities and the country, deploring that the works of improvement undertaken by the communes, through economic necessities, had ceased since 1892. There was much to be done for hygiene in Italy; Rome, the city in which baths were the only medicine of the ancients, had not a single public bath. He alluded to the evils produced by alcohol—a sad palliative for bad alimentation. He spoke of the hopes for the future to be obtained by a new legislation, provisions for safeguarding the public health, and by modern medical science. The address was loudly applauded by the crowded audience.

Since the Congress of Internal Medicine held in Rome last month, quite a war has been waged in a portion of the Italian press about the value of Maragliano's serum. This is due to two causes. In the first place the *Tribuna*, in its account of the discussion on serum therapeutics, stated that Professor Foa had admitted in his speech the value of Maragliano's serum. Foa wrote to the *Tribuna* denying that he had made such a statement. The matter was also taken up at the Congress by a young Roman doctor, who proposed that the Congressists should record their votes in favour or against the serum. Wiser counsels, however, prevailed, and the members declined to express an authoritative opinion on the matter. The other cause is the publication of the decree of the Minister of the Interior, who, by the advice of the Director of Public Health, has prohibited the use of the serum excepting under the direct responsibility of the preparer himself. Some of the papers blame the Director for not going far enough, and say that it is the duty of the authorities to prevent the circulation of a remedy which has not yet been proved efficacious, and therefore they consider the partial permission given by them a mistake, whereas other papers, on the contrary, think the decree too stringent.

FLORENCE.

The Hospitals of Florence.—Antitoxin Treatment of Diphtheria in Florence.—Professor Maragliano's Serum Treatment.—General News.

MANY institutions now engaged in active charitable work in Florence date their origin from the 12th and 13th centuries, and successive generations of Florentines have carried it on, in many cases without intermission, down to the present day. Hence we find bacteriological research and modern methods of treatment, antiseptics and hygiene, carried on side by side with traditional usages in buildings which carry the mind back to early mediæval times. There is not a single modern hospital in Florence; the new hospital for children is without the walls. Among the records of early charitable institutions of Florence are those founded by the Knights Templars and the Knights of the Order of St. John of Jerusalem in the 12th century. Then a leprosy hospital was founded by Vinciguerra Donati in 1186. Soon afterwards, in 1192, the hospital of Santa Maria was founded, but was converted into a foundling hospital in the 13th century. The principal hospital of the present day, Santa Maria Nuova, was founded in 1283, and about the same time the captains of the Bigallo determined to preside over the hospitals in order that the sick should be tended with brotherly love; the captains of Or San Michele took into their charge orphans, the destitute and widows, and the Brotherhood of the Misericordia undertook to transport invalids to the various hospitals, and the dead to their last resting place. This brotherhood is still performing the same work of mercy, and may be daily seen robed in long white gowns which completely cover the head, and are only pierced with eyelet holes, traversing the streets of Florence with their living or dead burden. In 1340 Villani's history records that there were more than 1,000 beds for the sick poor in Florence. At the end of the fifteenth century there were thirty-five hospitals, some special, some general, and some to give shelter to the destitute. All these institutions were established by the various guilds or privately endowed, and

If all the wealth left to Florence had been preserved to its original destination, it is said that half Tuscany would belong to institutions for the relief of the poor. In early days the money left to the poor generally reached their destination, a contrast says Pastarini, with present times, when much of that which was intended for the poor finds its way into the pockets of the employees of charitable institutions. Many of these charities were suppressed by the Council of Regency in 1790 and many more by Peter Leopold, who wished to centralise public institutions in the State. At the present day most of the hospitals are directly or indirectly under Government control.

Professor Mya, physician to the children's department of the hospital of Sta. Maria Nuova of Florence, gives his results of the antitoxin treatment of diphtheria as follows: The cases admitted between October, 1894, and October, 1895, number 112. All cases were verified as diphtheria bacteriologically. The rate of mortality was 18 per cent. Of cases demanding a recourse to tracheotomy, the mortality fell from 50 to 27 per cent. His method is to give one daily injection of serum for three days running, and he finds that this often suffices. He finds the treatment fails in the following classes of cases: (1) those in which the pharyngeal diphtheria is associated with early and serious affection of the submaxillary glands; (2) those in which the disease tends rapidly to involve the lower respiratory passages. The temperature is not a reliable guide to the adoption of serum treatment, as bad cases are frequently associated with a low temperature.

The following physicians record cases of phthisis treated by Professor Maragliano's method: Dr. Fusano, of Naples, records 1 case of marked phthisis which is rapidly improving, and promises to heal. Dr. Marucci, of Rome, records 12 cases which he divides into two groups: (1) those in which febrile reaction is marked; (2) those in which febrile reaction is not marked. Results: In all cases the fever has markedly diminished or disappeared; cough and expectoration have decreased; appetite and well being have supervened; weight is increasing. Dr. Rao, of Palermo, records 1 case which is rapidly improving under treatment. The tendency in Florence appears, however, to be to regard the treatment as of doubtful utility.

The King of Italy recently visited the Institution for Rachitis in Turin. In the afternoon he went to their Alpine colony. He spoke to many of the young people, and expressed his high satisfaction at the condition of the institute. He afterwards visited the Policlinic.

CHICAGO.

Local Depôts of Diphtheria Antitoxin.—Mississippi Valley Medical Association.—Death of Dr. John S. Clark.—The Medical Schools.

THE Health Department has followed the New York City plan of establishing local depôts throughout the city (about fifty in number) for the distribution of diphtheria antitoxin. As yet, it may be said, the experience in Chicago is similar to that of London—namely, there has been no marked decline in diphtheria mortality; and the number of cases seems quite unchanged. Indeed, with the commencement of fall school again, and the return of thousands of children to the city after a summer vacation, the disease is noticed to be on the increase. Experiments as to immunisation by the use of antitoxin have thus far not been at all extensively taken up. Indeed, we have no large children's hospitals wherein an extended use of the drug could be given.

As hinted in a former letter, the meeting of the Mississippi Valley Medical Association held at Detroit, Michigan, September 3rd to 6th, was well attended and of interest to those giving their time to the sessions. This Association could be one of considerable importance but for two reasons. The first is its silent opposition to the national body, the American Medical Association. Becoming a member of the one disallows one toward membership of the other; and the Mississippi Valley Medical Association, being the younger organisation, and working with ardour in the richest and most densely populated and progressive part of the country, has constantly alienated a large body of men from the parent society. If it can keep on doing this with satisfaction to its membership, well and good so far as its life is concerned,

but "there's the rub," and here enters the second obstacle. The leaders in the younger body are "soreheads" from the older one. They are bright men, but for reasons best known to themselves they have stepped aside from the American Medical Association, and are now the pushers in the new organisation. The truth of the matter is that the Mississippi Valley Medical Association, as a social organisation of physicians, is a success and may for a time continue so, but as a representative scientific body it is a very decided failure.

Dr. John S. Clark, one of the oldest practitioners of Chicago, and an obstetrician of recognised ability, expired suddenly from angina pectoris early in September. Dr. Clark not only occupied a high professional position, but was also a connoisseur of high-class art, a bibliophile, and had decided musical talent. He ever delighted in his fine collection of paintings, in his books, and in a large number of fine old violins; at the same time he was always ready to attend a woman in labour or relieve another in physical distress.

Colleges open soon, and there is already promise of a continued large attendance, notwithstanding the fear in some quarters that the inauguration of the four-year course would considerably decrease numbers. A new departure occurs this year in the examination of students entering their medical course, not dissimilar to the English requirements, namely, in the State of Illinois all students matriculating at medical colleges must first pass an entrance examination before a body of examiners taken from the State University and the State Board of Health, and who are not connected with the teaching force of a medical college. This will, it is hoped, very materially raise the standard of those entering upon the medical course.

CORRESPONDENCE.

THE BRITISH MEDICAL BENEVOLENT FUND.

SIR,—I shall be glad to avail myself of your kindness to acknowledge in the columns of the *BRITISH MEDICAL JOURNAL* the sums already received in answer to my appeal of November 9th, and to thank most heartily those who have so promptly come to our relief. In several cases members of the British Medical Association have sent us the half of their subscriptions returned after paying the expenses of the meeting in London last summer, and we should have reason to be very grateful if this example were followed by others. The present embarrassed state of the fund is caused, not by a falling off in the subscriptions, but by the non-arrival of large donations, which are always an uncertain source of income.

	£ s. d.		£ s. d.
Sir Joseph Lister	25 0 0	Brigade Surgeon Clarke ...	1 1 0
Dr. Horrocks	2 2 0	Messrs. Curtis and Co.	
Dr. Bowland	0 10 6	(subscriptions)	1 1 0
Lennox Browne, Esq.	2 12 6	A grateful patient of Mr.	
Dr. Douglas Powell	10 0 0	Jabez Hogg	5 0 0
Paterson Sheehy, Esq.	20 0 0	T. D. Ransford, Esq. ...	5 5 0
T. Charteris White, Esq.	1 1 0	Dr. Haviland	10 0 0
Dr. Kelly	5 5 0	Dr. Swain Scriven	1 1 0
Dr. Barnes	10 0 0	One who has benefited, per	
Beta	10 10 0	Dr. Swain Scriven	0 3 0

Besides these may be mentioned a donation of £21 from Mr. France, a member of the Committee; £5 from Mrs. Cesar Hawkins, in addition to a previous donation of £10 10s.; and £10 10s. from the Treasurer.

Subscriptions and donations may be sent to the Treasurer or to the Honorary Financial Secretary, Dr. Samuel West, 15, Wimpole Street.—I am, etc.,

Brock Street, W., Nov. 15th.

W. H. BROADBENT.

SIR,—Sir W. H. Broadbent's letter in the *BRITISH MEDICAL JOURNAL* of November 9th tempts me once more to ask the question, Cannot some united action be taken by the Branches of our Association which will render such appeals to the profession unnecessary? With a little tact on the part of secretaries of Branches a large proportion of the members might be induced to give a subscription of five shillings a year each to this fund. This is a small consideration to each member, but in the aggregate, assuming our British membership to be 10,000, there would be a total sum of nearly £1,000 obtained

for this fund with very little trouble. We are approaching the end of the year. Let an earnest appeal be made to the Branches to ask for this five-shilling subscription with the coming year, and I am sure the result will be satisfactory. More than ten years ago I got a resolution passed that each member of our Branch should be asked to give this sum annually, and the result has been that between £33 and £34 has been sent up to the fund every year, representing a subscription of five shillings willingly paid by nearly three-fourths of the members.—I am, etc.,

Cardiff, Nov. 11th.

A. SHEEN,
Hon. Co-Secretary, South Wales and
Monmouthshire Branch.

P.S.—Such a scheme as this would not in any way interfere with the wishes of those who may be more generously disposed towards this fund.

SIR,—Having, in the *BRITISH MEDICAL JOURNAL* of November 9th, read the urgent pleadings of Sir William Broadbent on behalf of the British Medical Benevolent Fund, I have had the pleasure of sending to him the half of my contribution to the Arrangement and Reception Fund returned to me from the surplus after all expenses were paid. I offer as a suggestion that if those of us who subscribed to that fund returned their moneys to the same destination much valuable aid would be rendered to a most deserving charity. In this way probably about £1,000 might be raised before the end of the year.—I am, etc.,

Belgrave Road, S.W., Nov. 9th.

T. CHARTERS WHITE.

HOSPITAL ABUSE AT BRIGHTON.

SIR,—Enclosed I forward you a copy of a joint letter, signed by a large number of old-established and well known medical men in practice in Brighton and Hove. It bears upon a most important subject, and I feel sure you will agree with me in saying that it supports the contention set forth in my previous letters, that there is an amount of hospital abuse in Brighton which demands immediate investigation and remedy.—I am, etc.,

Hove, Nov. 11th.

FRANCIS J. A. WARING.

HOSPITAL ABUSE AT BRIGHTON.

GENTLEMEN.—

November 4th, 1895.

We, the undersigned medical men, beg to call your attention to the gross and increasing "hospital abuse" in Brighton and Hove by a class of people well able to pay for private medical attendance. To no section of the community is this better known than to the general practitioner, who is constantly coming across people in well-to-do circumstances who do not hesitate to admit that they have had tickets for either indoor or outdoor treatment at the various charities in the town. That 15,000 patients were attended at these charities during 1894 are figures which speak for themselves. This is quite independent of the work-house and sanatorium, which would greatly add to the number. Of the 15,000 births during 1894, a little over one-third were attended by the West Street Lying-in Institution. In addition to this, there were some attended to the union, and others by the Society for helping young women in their first fall. To many this would appear incredible, and we are sure that all will agree that it demands immediate explanation from that institution. We are given to understand that many of the patients are insured in the various benefit societies, where they receive a sum of money at the birth of each child to help defray expenses. We are fully convinced of the fact that the institutions most abused are the General Dispensary and those hospitals which are devoted to the treatment of special diseases. As medical men we are fully alive to the needs of the poor, who, in the hour of sickness or injury, require skilful and merciful attention; but we are also convinced of the fact that nothing is more demoralising than charity misapplied.

In conclusion, we appeal to the Committee of the different charities in Brighton and Hove to use their best endeavours to put a stop to the abuse, which is not alone an injustice to the medical profession, which does so much gratuitous work for the poor, but at the same time is an injustice to the subscribing public, who have a right to demand that their generosity is not abused:

To the Chairmen and Committees of the various charities in Brighton and Hove.

ENTERIC FEVER IN INDIA AND THE "WATER-BORNE" THEORY.

SIR,—I was glad to see in the *BRITISH MEDICAL JOURNAL* of November 9th a communication on the above subject from my old friend and colleague, Retired Surgeon-Colonel Welch, than whom I know not a more acute or accurate observer. The doctrine inculcated by this experienced medical officer is one with which I am in complete agreement, namely, "that the disease is essentially the same as the European, clinically, pathologically, and etiologically, following the same laws, and doubtless due to the same one cause." This is the doctrine taught by me at Netley, in my lectures there, and in my work on *Tropical Diseases*, published by Macmillan and Co., in 1888. A reference to this work will also show that the "waterborne" theory of enteric fever and cholera, so much insisted on of late, was in like manner an important point in my Netley teaching, as well as in the work above referred to. I have shown that it is no answer to insist, as has often been done, that enteric fever prevails often in barracks where the water supply is above suspicion, for the simple reason that our soldiers are not confined to barracks. It is notorious that they frequent "the native bazars and villages within easy distance of our cantonments, which stand on soil for ages sodden with excremental matter, and the tanks and walls of such places are befouled with all manner of impurities." Drinks of various kinds are prepared from water taken from such sources, are freely used by our young soldiers, and to this source a large amount of the cases of enteric fever can without question be traced. At p. 80 I give an example (on the high authority of Surgeon-General Sir Anthony Home, V.C.) of enteric fever clearly traced in the 2nd battalion of the 13th Regiment at Kamptee, to a well into which water had percolated from a wash-house and drain. The sufferers from the disease in this case were those, and those only, who partook of water from this well.

I take leave to add that I have been equally explicit in teaching that the great agencies in the propagation of cholera are two—human intercourse and water.—I am, etc.,

Southampton, Nov. 12th.

W. C. MACLEMAN.

THE SCHOTT TREATMENT OF HEART DISEASE.

SIR,—Dr. Poore has raised a very interesting discussion as to how the space abandoned by the heart in shrinking becomes occupied. I think I can throw some light upon the subject from a case now under my care.

The patient is a young girl of 16, who had acute rheumatic endocarditis in February last. By August there was very considerable auricular dilatation. I then gave her on alternate days seven saline baths, following the directions published in Dr. Thorne's book, with the result that the cardiac dulness at the base eventually receded half to three-quarters of an inch. Gradually the chest "fell in" from the second to the fourth rib over the area of dilatation. The recession of ribs and spaces was so marked that the girl's mother asked me with some anxiety as to its significance. Further, this having reached the maximum about the fifth bath, I found that the next two baths had no marked beneficial effect, and they were discontinued. The recession still exists, but is not so marked. Percussion shows that the auricles are dilating again, and I propose giving a fresh series of baths.

It is thus very evident that the lung does not dilate properly, even after a considerable period—two months—has elapsed. In this case there is very little ventricular alteration, and the apex beat, though diffused, can be localised as most intense in the normal situation. Local recession of the thoracic wall is best shown in young people, and it would be interesting to learn if this always takes place under similar conditions.—I am, etc.,

Loughton, Nov. 9th.

A. BUTLER HARRIS, M.A., M.B. Oxon.

SIR,—Dr. Poore, in commenting upon the paper by Dr. Saundby upon the Schott treatment of heart disease, gives an interesting explanation for the reduction of cardiac dulness by inflation of the lungs. While a visit to Naunheim last May convinced me that the treatment carried on there is of great

¹ Vide *Tropical Diseases*, p. 79.

value in some forms of cardiac disease, the opportunity kindly given of testing the reduction of cardiac dulness during a bath did not convince me that the heart I examined became diminished in size. Reduction of cardiac dulness there undoubtedly was, but I could feel the impulse in the same position after as before immersion, and came to the conclusion, therefore, that the anterior border of the left lung had advanced over the heart.

It is a curious fact, however, that patients may in some degree experience immediate relief after the first bath. One gentleman told me that he could not walk from his hotel to the bath-house without a rest on the way, but could after the bath return without any such rest. What is the explanation of this relief? Is it due to the tepid temperature of the bath acting as a tonic to the vasomotor system; does slight loss of heat from the body set up weak electrical currents that combined act as a stimulus to the nervous system; or do some of the salts in solution find entry to the circulation, as Dr. Schott suggests, by the sweat glands? The last suggestion physiologists no doubt consider improbable, but it is worthy of note that Dr. Ringer and other observers have shown the value of calcium, potassium, and sodium salts upon cardiac action; of which salts the Nauheim water contains an exceptional quantity. It has occurred to me that calcium chloride might be tried internally in those forms of heart disease most benefited by treatment at Nauheim.—I am, etc.,

Glifton, Bristol, Nov. 11th.

THEODORE FISHER.

"MEDICAL AID FREE, WITH A POUND OF TEA."

Sir,—It is with profound regret I have to acknowledge that up to the moment of writing I have been unacquainted with the various letters, etc., pertaining to the above subject.

I beg to state that from representations made to me prior to my acceptance of office I looked upon the matter as an ordinary "tontine society."

I, like Dr. Swanson, almost immediately afterwards, left town upon my holidays, and during my absence I was made acquainted with the mistake I had made. I immediately (prior to my return) sent in my resignation, and so terminated my connection with the firm.

Not having had the remotest notion of committing any breach of medical ethics, I trust this may be deemed a sufficient explanation of my conduct.—I am, etc.,

Liverpool, Nov. 11th.

WM. M. PEARCE.

Sir,—The letters and correspondence on the above subject, which, only brought before my notice a few days ago, I extremely regret, otherwise I would long since have informed you that the moment I found out it was not what it was represented to me to be, namely, a "tontine," I immediately severed my connection with the firm. I hope, Sir, that you and your readers will see that I was completely misled, and that I did the only thing that lay in my power by resigning at once.—I am, etc.,

Liverpool, Nov. 11th.

J. B. FORSTER.

PORTSMOUTH MEDICAL UNION.

Sir,—I am desired by the Committee of the Portsmouth Medical Union to thank you for your assistance in the columns of the BRITISH MEDICAL JOURNAL in our "battle with the clubs" here in Portsmouth. If we can only secure the non-intervention of outsiders we shall gain the day.—I am, etc.,

Southsea, Nov. 10th.

T. FREDERICK PEARSON, M.D.,

Honorary Secretary.

WELL-TO-DO PATIENTS IN RATE-SUPPORTED HOSPITALS.

Sir,—In the BRITISH MEDICAL JOURNAL of November 9th Mr. Samuel Osborn complains that well-to-do patients avail themselves of the fever hospitals under the Metropolitan Asylums Board, and states that they are entitled to, and the authorities have no power to recover fees. If this really be the law in London, it is most extraordinary that here in Willesden we seem to have adequate powers to recover expenses incurred through treating patients in our isolation hospital, and, strange to say, our legal advisers assert that we are compelled to charge the patients; the expenses of their treatment is "deemed to be a debt," according to the words

of the statute, but we have the power to remit the fees if the patient is too poor to pay. This seems to me altogether too much the other way; and as our hospitals have not been abused by well-to-do patients, I have strongly opposed charging for compulsory attendance in a fever hospital as against public policy and contrary to the spirit of the Act. Opinion is very evenly divided on our Council, those against charging only gaining the day last meeting by one vote.—I am, etc.,

W. WOODLEY STOCKER, M.R.C.S. Eng., L.R.C.P. Lond.,

Member Sanitary Committee Willesden District Council, and member Visiting Committee Willesden Fever Hospital.

Willesden Green, N.W., Nov. 11th.

PROFESSIONAL ADVERTISING.

Sir,—Will you allow me to say that I entirely agree with the views expressed by Dr. D. S. Owens in the BRITISH MEDICAL JOURNAL of November 9th on the above subject. I attended almost all the meetings of the Ethical Section at the last meeting of the British Medical Association, and I was much struck with the amount of illiberal nonsense ventilated by the various speakers. Especially did I notice the ridiculous fallacy on which Dr. Potter based one of his objections to professional advertising, which your correspondent justly exposes. Dr. Potter has no right to assume that an advertisement must necessarily be fraudulent, as it would certainly be "to promise some definite cure or result." There are myriads of advertisements which would not come under this category and to which no sufficient moral objection could apply. Dr. Potter's confusion arose from his mixing up violations of morality with violations of conventional usage. The former may be held to be unchangeable; the latter to be continually changing; and it is under the latter that the various forms of medical advertising fall. So far as I can comprehend, nothing that is straightforward and truthful can be considered in any sense a breach of morals; it may certainly be a breach of conventional usage; but on this point people have a right to and do judge for themselves in and out of professions. There is no profession that advertises more effectually than the medical in diversified oblique modes, and there is no section of the profession so notoriously guilty of oblique advertising as those who affect to maintain the so-called honour of the profession, and at the same time crush the junior members by arbitrary, unreasonable, and scandalously unfair enactments.—I am, etc.,

Glasgow, Nov. 9th.

D. CAMPBELL BLACK, M.D.

EXIT EUSAPIA.

Sir,—My attention has been drawn to an article in the BRITISH MEDICAL JOURNAL of November 9th in which reference is made to experiments with Eusapia Paladino in which I have taken part. In the course of the article it is implied that I and the other investigators mentioned "accepted the foolish wonders of spirit-rapping and table-turning with simple faith" and as "direct revelations from the unseen," and sought "spiritual edification" from them. It is further affirmed that "had Mr. Maskelyne not been present at the recent sittings at Cambridge, Eusapia's shrine would probably not have been deserted even now."

I must ask leave to state that these statements and implications are one and all entirely without foundation so far as I am concerned. I have never accepted the wonders of spirit-rapping and table-turning; and if I had I should never have sought spiritual edification from them. The trickery, which the experiments at Cambridge proved to have been used by Eusapia had been long ago suggested by Professor Richet himself, and more recently had been precisely and fully described by Mr. Richard Hodgson, the Secretary of the American branch of the Society for Psychical Research, in a paper criticising the conclusions of the Italian *seances* and of Professor Lodge. It was to test the issue thus raised between two members of our group of investigators—Professor Lodge and Mr. Hodgson—that the experiments at Cambridge were arranged. Mr. Hodgson himself took part in them, and they ended in entirely confirming the opinion that he had previously expressed. And though I set a high value on Mr. Maskelyne's acumen and skill, his intervention in this case did not in fact affect the progress of the investigation.

I may add that the general drift of your article shows a complete ignorance of the work in which the group of investigators to which I belong have been engaged since the foundation of the Society for Psychical Research thirteen years ago. Throughout this period, we have continually combated and exposed the frauds of professional mediums, and have never yet published in our *Proceedings* any report in favour of the performances of any of them.—I am, etc.,

Cambridge, Nov. 12th.

HENRY SIDGWICK.

"S." We gladly accept Professor Sidgwick's assurance that he does not accept the wonders of spirit-rapping, and that he has not sought spiritual edification from them. This being so, however, we would respectfully ask, *que diable est il allé faire dans cette galère?* If the Society for Psychical Research do not seek for signs and wonders, what go they out for to see? We can understand the position of those weaker brethren who expect to find evidence of a future life in mysterious taps and pinches, but how men like our distinguished correspondent and his colleagues can think such rubbish worth investigating as "phenomena" or "manifestations of psychic force" passes our comprehension. As regards Mr. Mackelyne's share in the exposure of Eusapia, there appears to be a difference of opinion between that gentleman and Professor Sidgwick, and we must leave them to settle the matter between them. It is a fact that Mr. Mackelyne was, apparently at the suggestion of Mr. Andrew Lang, called in to assist in unveiling the prophetess, and we may add that we entirely agree with Mr. Lang in relying more on the conjurer than on the psychical researchers. As regards the work of the Society for Psychical Research, our complaint against it is not that it publishes reports in favour of the performances of professional mediums, but that it wastes time which might be given to the solution of problems urgently concerning the welfare of mankind in the investigation of phenomena which have their origin in delusion when they are not the result of jugglery and imposture, and which in any case are unworthy of the notice of serious men.

THE MARCHING POWERS OF OUR SOLDIERS.

SIR,—Will you kindly allow me to confirm the letter of Surgeon-Major F. P. Nichols in the *BRITISH MEDICAL JOURNAL* of November 9th? He is quite right in saying the ammunition boots are good boots, "but they need intelligent treatment—and feet as well."

For India and Burmah boots of brown leather are preferable to black ones, as the black colour absorbs heat far more than brown. Excellent boots are now supplied from the army boot factory at Cawnpore, N.W.P., where Messrs. Cooper, Allen and Co., as part of their contract, not only permit continual Government inspection, but also teach classes of soldiers to make and repair boots. This is a practical detail for which the army has to thank Lord Roberts, lately Commander-in-Chief in India. Dr. Nichols is quite right to stuff the boots to prevent any friction between the boot and the foot, a fertile cause of "blisters of the feet," which produce intense agony. But in India and Burmah socks wear out very fast, and it is often impossible for soldiers and Sepoys to get new socks when the old ones are worn out. Moreover, it is difficult to get socks to fit the feet, so Messrs. Cooper, Allen and Co. have introduced a "foot cloth" of cotton, tough, but soft and flexible, which washes well and is cheaper than socks. It measures 19 by 15 inches, and can be wrapped round the foot so as to form a comfortable covering. In practice it is found that neither soldiers nor Sepoys object to wash this foot cloth, even Hindus washing it as they do their own "dhoties," or waist cloths.

I used to give my men German "foot powder" (composed of French chalk, two-thirds, and salicylic acid, one-third), which helps to save the skin from being chafed. If there were intertrigo in the clefts between the toes, I packed them with a little cotton-wool dipped in boracic acid, and this sprinkling rapidly healed the abrasion, while it had the additional advantage of deodorising the feet, which are apt to stink horribly when no water is obtainable for washing them.

There is one weak point which could be remedied with very little trouble, and no expense worth mentioning. The so-called "tongue" of leather between and beneath the laces is not proof against sand, dust, or small shingle, all of which may cause serious abrasions, and these are so painful that a

man cannot march with them, still less shoot. The remedy is very simple. Put in a "full bellows tongue," as shoemakers call it, between the "quarters" of the boot, as is done for shooting boots, extending from side to side, and sewed to the quarters beyond the part where the eyelet holes and hooks are placed for the heel laces. I find a piece of leather 7 inches by 5 inches is quite large enough to extend thus from side to side, and from the "vamp" to the top of the boot at the ankle. This piece can be made of the so-called "oil" leather, that is, the leather which is too thin to be used in any other part of the boot. This "full bellows tongue" is not only dust proof, but it also permits the boot to be opened so wide that it can be removed without hurting the wearer if he happens to be wounded, or to sprain his ankle, no mean advantage, *experto crede*. But in mountain warfare the ammunition boot requires to be supplemented by something else, for the leather sole slips on dry grass and on smooth rocks, so that the wearer becomes very soon fatigued.

I am glad to be able to announce that for this also a remedy has been found as I have recently received a letter, dated October 18th, 1895, from my old friend, the Inspector General of Prisons, Central Provinces, Nagpore, India, to say that he can utilise prison labour to make "grass shoes" of jute and aloe fibre, which do not slip either on rocks or grass. Grass shoes have always been worn by the native inhabitants of Kumaon and Kashmir, so that it is well that our soldiers should benefit by the customs of these mountaineers. They are very like the "bathing shoes" now worn at home when people have to bathe on rocks or a shingly beach, and they are noiseless. They will probably become popular for sport and for lawn tennis, and as they are very cheap and have no leather in them, they can be made in prisons by all castes of Hindus without difficulty, and can be worn by all classes of natives without any caste prejudice.

It is fortunate that the invention can be so useful alike to Europeans and natives, to soldiers and to civilians.—I am, etc.,

R. TEMPLE WRIGHT.

November 12th.

Brigade Surgeon-Lieutenant Colonel, retired.

D.P.H. EDINBURGH CONJOINT BOARD.

SIR,—I agree in the main with your correspondent in the *BRITISH MEDICAL JOURNAL* of November 9th on this subject, and I have heard the same opinions exactly uttered by not one or two, but by many medical men. As a medical officer of health of some experience both in urban and rural districts, my opinion is that the utmost which should be expected of candidates for the chemical part of D.P.H. is that they should be able to analyse quantitatively and bacteriologically, as well as qualitatively, air and water; should be able to use the microscope intelligently in determining adulteration in common foods, and should be able to understand and interpret the results of chemical analyses of food materials.

But to expect medical officers of health to have the knowledge and proficiency of public analysts is to expect far too much. Every sanitary authority either has its own analyst or the use of the county analyst, and the places in which the joint office is still preserved are getting fewer every year. I believe the Local Government Board sets its face against the two offices being united on the ground that such an arrangement places too much power in the hands of one man.

Is it not possible to bring about some rough kind of uniformity with regard to the regulations in connection with the various D.P.H. examinations? The number of medical men who are debarred from taking a public health degree because they are unable to disentangle the knots of red tape in the regulations of different examining bodies is, believe me, simply legion.

Some universities demand a residence of six months, others recognise only certain laboratories; others specify for study certain statutes, some of which have absolutely nothing to do with a medical officer of health; others demand that at the practical chemistry examination the candidate shall make his own quantitative solutions, and so on.

All these things make men shy of public health diploma work, and as a consequence our public health service does not contain everywhere what one might term expert men. The remedy for the whole matter, to my mind, would be to make the examinations above all things practical, and to have as far as possible medical officers of health as

examiners, to have uniformity of regulations, and to make the possession of a public health diploma or degree necessary for the holding of all public health appointments, small towns or villages to be combined together if necessary.—I am, etc.,

November 13th.

VARIOLA.

DIPHTHERIA ANTITOXIN AS A CULTURE MEDIUM FOR THE TREATMENT OF BACILLUS.

SIR,—In reply to the letter of Dr. W. A. Hollis, in the *BRITISH MEDICAL JOURNAL* of November 9th, respecting the employment of diphtheria antitoxin serum as a medium for cultivating the diphtheria bacillus, I may say that I have made trial of Drs. Wright and Semple's method with satisfactory results. Three inoculations were made as directed from membrane expelled from the trachea of a severe case of diphtheria in a boy, aged 5 years, which proved fatal on the 5th day after tracheotomy and two antitoxin injections. At the end of twenty-four hours colonies had developed at the sites of inoculation, and these showed on microscopical examination crowds of short and long bacilli, with cocci. One little detail may be added to Drs. Wright and Semple's directions: the bottle can be kept at practically body heat during the daytime by carrying it beneath the waistcoat as they describe, but what is to be done at night? I placed the bottle in my axilla, secured by a string round the neck.

I take it that the antitoxic serum serves in this capacity simply as a culture medium, any special properties which it possesses being destroyed by the heat applied to produce coagulation.—I am, etc.,

Plymouth, Nov. 9th.

H. W. WEBBER.

SIR.—In the *BRITISH MEDICAL JOURNAL* of November 9th Dr. W. A. Hollis, of Brighton, expresses the view that antitoxin contains a something—possibly a ferment—which when introduced into the body of a person suffering from diphtheria effectually prevents the growth of the Klebsiella bacillus, and that the fact that antitoxic serum is a good culture medium for the diphtheria bacillus is incompatible with any therapeutic value of this serum.

Indeed, in one of his earlier papers on the subject, points out the fact that the serum of animals immunised against diphtheria is an excellent culture medium for the bacillus of this disease. Not only is this true, but the bacillus actually increases in intensity of virulence—a fact first demonstrated by Gabritschewsky.

Notwithstanding, it is, I need scarcely say, a comparatively easy thing to render certain animals insusceptible to diphtheria by the use of this very serum which *in vitro* furnishes so good a nutrient fluid. This fact has been demonstrated times without number by bacteriologists; its explanation is quite another thing. The theory of phagocytosis, so brilliantly upheld by Metchnikoff, appears to furnish the true explanation of the *modus operandi* of preventive serums. These serums act as stimulants to the phagocytic cells, which then destroy the microbes by a kind of intracellular digestion. The presence in the serum of a substance or substances capable of stimulating the living phagocytic cells in the body is in no way incompatible with the nutrient properties of the serum in a test tube. Moreover, in such a disease as diphtheria, in which the blood is free from bacilli, and in which the fatal result is due to a soluble poison, the value of the serum is owing largely to the fact that the defensive cells are rendered much less susceptible to the necrotising power of the toxin. The defence is a living active process.

Perhaps the most lucid and succinct account of the present question is to be found in the remarks of M. Roux at the Congress of Buda-Pesth, vide *Annales de l'Institut Pasteur*, October 1894.—I am, etc.,

WM. ST. C. SYMMES, M.B.Aberd.

Plymouth, B.W., Nov. 10th.

THE MORTALITY OF THE PRESENT EPIDEMIC OF DIPHTHERIA.

SIR.—The tabular statement of the general mortality from diphtheria in the metropolis during the last six weeks published in the *BRITISH MEDICAL JOURNAL* of November 2nd is of great interest. On reference to it, it will be seen that the proportion of the total deaths to the total notifications does not very materially differ from that of the deaths to the

admissions in Asylums Board hospitals. In the latter the mortality ranges from one death in every eight cases to one in every four, with a fraction over. In the former it varies from a little over one in every seven to one in five; in each case the greater mortality being in the later weeks. Now, of course six weeks is too short a period for safe guidance as to the average mortality or even as to the effect of a certain treatment, but it is disappointing to observe there is no such evidence of the overwhelming value of the serum treatment as one had hoped for. In the hospitals, where no doubt it is used with every skill and precaution, the death-rate is about the same as in London generally. It would be interesting and useful to know whether the metropolitan mortality from this cruel disease differs very markedly from the rate of, say, two years since.—I am, etc.,

November 6th.

SENIOR.

UNITED KINGDOM POLICE SURGEONS' ASSOCIATION.

SIR.—In consequence of the circular issued by the late Home Secretary, Mr. Asquith, to those borough and county councils which had not hitherto appointed police surgeons, many new appointments have been made. Notices of some of these have been sent to us, and in each case a nomination paper has been sent. But there may have been some gentlemen appointed of whom we have not heard, and who may wish to join this Association, of which Sir H. D. Littlejohn is the President, and which has already done much to promote the interests of police surgeons. Will you, therefore, kindly allow us to state that we shall be most happy to send a printed form of application for membership to any newly appointed police surgeon, or to any other police surgeon who is not already a member.—We are, etc.,

FREDK. W. LOWNDES.

40, Knight Street, Liverpool.

H. CULLIFORD HOPKINS,

8, Bladud Buildings, Bath.

Hon. Secretaries to the Association.

November 13th.

CANCER STATISTICS.

SIR.—The conclusions against which Dr. Newsholme animadverts are based upon the best statistical information available. These conclusions are not absolutely beyond discussion. Personally I regard the data on which they are based merely as straws, showing which way the wind blows. When much cannot be got out of a complex mass of vital statistics, I am thankful to get a little. Dr. Newsholme knows very well that the necessary data for such treatment of the subject as he lays down do not exist. It would have been more appropriate if Dr. Newsholme had addressed his criticisms to the Registrar-General rather than to me.—I am, etc.,

Preston, Nov. 9th. W. ROGER WILLIAMS.

OBITUARY.

FREDERICK COCK, M.D., M.R.O.P.

DR. FREDERICK COCK sprang from a yeoman stock, settled in Lydd, Kent, since the fifteenth century. He was educated at the grammar school at Ashford, then went to Boulogne, where he was apprenticed to the brother of Pelletier, the discoverer of quinine. He attended the art classes there, his tutor being the afterwards celebrated Mariette Bey, the Egyptologist. He also was a diligent student at the hospital. In 1847 he matriculated at University College, London, and at University College Hospital he served the office of House-Surgeon to Arnott, and was the first House-Physician to Sir William Jenner. He did much work also with Parkes. He was one of the first to whom ether was administered. The year he joined was remarkable for the men who afterwards distinguished themselves. Sir Russell Reynolds, Sir Henry Thompson, the late Wilson Fox the elder Gamgee, Sir Joseph Lister, and many other leading lights in the profession were his classmates. After taking the diploma of M.R.O.S. in 1851 he was compelled through ill-health to leave London, and proceeded to Edinburgh, where he took the degree of M.D. in 1853, with honours. It shows the insanitary condition of the

city at that time, that of seven men who went there as undergraduates, no fewer than three contracted typhus from the patients in the infirmary. Dr. Cock had it so severely that he was nine weeks in bed.

In 1854 he studied at Paris and Berlin. When at the latter place he often met at a common friend's Prince Bismarck, who even at that time had very definite ideas on the unification of Germany, and the two had many conversations on political questions. In 1855 he returned to England, and in 1856 he married and settled down to practise as a physician in the house at Westbourne Park, London, where, nearly forty years after, he died. He did work for Sir Wm. Jenner, and was appointed physician to the Farringdon and Western General Dispensaries, both of which institutions he served for many years, and to both of which he was the senior consulting physician. In 1863 he became a Member of the College of Physicians. He was a member and past-president of the Harveian Society, a member of the Epidemiological Society and the Sanitary Institute.

Of the most charitable and kindly disposition, he was universally beloved, and his skill was always at the disposal of the sick and needy, whom he helped with unsparing hand. An attack of influenza last February enfeebled him very much; since then he developed a chronic gastric catarrh, which greatly reduced him. The immediate cause of death was apparently the rupture of an aneurysm or large vessel into the gullet or stomach. During his illness he was attended by his son, Dr. F. William Cock, his old friends, Messrs. Lake and Tapson, with the occasional kindly aid of Dr. Goodhart. His funeral took place on November 9th, at Appledore, Kent. He was followed to the grave by a great crowd of old friends and patients.

We regret to have to record the death of Mr. ARTHUR SHRAD LAWRENCE, eldest son of Dr. A. G. Lawrence, J.P., of Chesham. Mr. A. S. Lawrence, who was a student of the Middlesex Hospital, obtained the double qualification at the recent examinations of the Conjoint Board. On November 1st, while riding at Chesham, he was thrown from his horse and sustained a fracture of the skull, to which he succumbed after lying unconscious for thirty hours.

MR. CALED ROSE, of Ipswich, who died on November 7th, was the son of Dr. Caleb Burrell Rose, of Swaffham, and was born in 1820. He studied medicine at Guy's Hospital and in Paris, and qualified as L.S.A. in 1842, taking the F.R.C.S. Eng. in 1850, and becoming M.R.C.P. Lond. in 1878. After practising in partnership with his father, he went to London in 1854, but in the course of time he suffered from asthma, and believing that a change to country air and surroundings was advisable, he went to Ipswich in 1863 with the intention of retiring from the active pursuit of his profession, but as time went on he resumed practice. The funeral took place at Ipswich Cemetery on November 11th.

MR. WILLIAM CUTHBERT BLACKETT, J.P., of Ripon, who has just died, aged 85, was the son of Mr. William Blackett, of Durham, and qualified as M.R.C.S. and L.S.A. in 1853. He held the post of medical officer to the Durham Rural Sanitary Authority and the Brandon and Byshottles Local Board, both of which offices he resigned a few years ago, when he retired from private practice. In 1857 Mr. Blackett was appointed Chief Magistrate for the city of Durham.

MR. W. R. ANCRUM, of St. Leonard's Court, near Gloucester, who died recently, was born in 1816, studied medicine at University College, and qualified as M.R.C.S. and L.R.O.P. Lond. in 1839, and F.R.C.S. and M.R.C.P. in 1851. He afterwards went to Mexico, where he practised for four years; from there he went to Valparaiso, Chili, where he practised for fourteen years. He finally retired from practice in 1860. Mr. Ancrum took a great interest in county asylums, and was for a number of years Chairman of the Committee of Visitors. He had also been for twenty-seven years Chairman of the Infirmary Governors, and in 1892 his portrait was presented by Mr. Birchall to the Gloucester Infirmary.

NAVAL AND MILITARY MEDICAL SERVICES.

CHANGES OF STATION.

The following changes of station amongst the officers of the Army Medical Staff have been officially notified to have taken place during the past month:

	From	To
Surg. Col. J. W. Matham, M.D.	York	C. of Good Hope.
W. A. Catherwood, M.D.	Colchester	Gibraltar.
Brig.-Surg.-Lt. Col. J. F. Supple	Jersey	India.
A. W. Duke, M.D.	Canterbury	Ceylon.
Surg.-Lieut. Col. A. Kirwan	York	Jersey.
Surg. Major A. E. Hayes, D.S.O.	Aldershot	Hong Kong.
P. H. Johnston, M.D.	Colchester	"
J. J. Lamprey	Leeds	Cork.
H. L. Donnan, M.D.	Tipperary	Madras.
J. G. MacNeece	York	Bermuda.
A. W. P. Inman, M.B.	Barbadoes	India.
A. Hewitt	Leeds	York.
J. G. W. Crofts	Fermanagh	Athlone.
W. J. Baker	Canterbury	Bermuda.
Surg.-Capt. N. Manders	Aldershot	Ceylon.
G. E. Hale, D.S.O.	Manchester	"
M. L. Hearn	Setley	Straits Settlement.
C. A. Lane, M.D.	Colchester	"
C. G. Woods, M.D.	Almeida	Portsmouth.
H. H. Brown, M.B.	Gloucester	Hong Kong.
T. H. Corkery	Gravesend	Bombay.
S. J. W. Hayman	Lydd	Canton.
J. S. Edye	Aldershot	Hong Kong.
C. R. Elliott, M.D.	Holywood	Chatham.
G. S. Walker, M.B.	Fort Camden	Cork.
Surg.-Lieut. H. E. B. Porter	Lydd	Brighton.
H. V. Fyenne	Gosport	Aldershot.
G. Dansey-Browning	Ayr	Sharncliffe.
C. K. Morgan, M.B.	Canterbury	Fort Camden.
J. H. Whitehead	Cork	Bombay.
J. A. Marston, M.B.	"	Canterbury.
F. E. Gunter	Dover	Jersey.
J. H. Campbell	Dublin	"

Brigade-Surgeon-Lieutenant-Colonel H. W. A. Mackinnon, D.S.O., recently retired, has been posted to Reading.

THE NAVY.

The following appointments have been made at the Admiralty: FRANCIS E. M. LOFTIE, Fleet Surgeon to the *Medea*, November 12th; RICHARD G. BROWN, Fleet Surgeon, to the *Medusa*, November 12th; EDGAR R. PEMSEY, Staff-Surgeon, to the *Phoebe*, when recommissioned; JOHN L. BAGNALL-OAKLEY, Staff-Surgeon to the *Sappho*, undated; HUGH ST. D. GRIFFITHS, Surgeon, to the *Scalione*, November 8th; ROBERT HICKSON, Surgeon, to the *Vivid*, November 8th; LEO E. JAMES, Surgeon, to the *Petrel*, additional, for Ascension Hospital, November 11th.

ARMY MEDICAL STAFF.

SURGEON COLONEL W. A. CATHERWOOD, M.D., lately Principal Medical Officer of the Eastern District, has been appointed Principal Medical Officer at Gibraltar, in place of Surgeon-Major-General R. Lower, who has been placed on the retired list owing to age.

Brigade-Surgeon-Lieutenant-Colonel R. C. EATON is appointed to officiate as Principal Medical Officer of the Allahabad and Nerbadda Districts, vice Surgeon-Colonel C. MacD. Cuffie, who succeeds Surgeon-Colonel T. Maunsell as Principal Medical Officer of the Rawul Pindi District.

Surgeon-Major THOMAS LEWELLYN NASH, M.D., died at Sandymount, Dublin, on October 22nd. He was appointed Assistant-Surgeon, February 14th, 1862; Surgeon, January 18th, 1869; and Surgeon-Major, February 14th, 1872. He retired on half-pay, October 6th, 1872.

INDIAN MEDICAL SERVICE.

DEPUTY SURGEON-GENERAL ROBERT SANDER BATESON, late of the Bengal Establishment, died on October 26th. He was appointed Assistant-Surgeon, February 30th, 1859; became Brigade-Surgeon, October 20th, 1862; and retired with the honorary rank of Deputy Surgeon-General, September 1st, 1880. He served in the Indian Mutiny campaign in 1857-58, and was present in the actions near Agra and in the engagement at Dewas against Tantia Topce (medal).

THE VOLUNTEERS.

THE undermentioned gentlemen are appointed Surgeon-Lieutenants to the corps specified, dated November 15th: ROBERT HALL WRIGHT, 1st Leicestershire and Cambridgeshire Artillery; ANTHONY FRED NUTTALL, M.B., 1st Volunteer Battalion the Lancashire Fusiliers; LOUIS JOHN GERMARD CARR, M.D., 1st Surrey (South London) Rifles.

Surgeon-Major E. SAND, 2nd Volunteer Battalion the Essex Regiment, is appointed Brigade-Surgeon-Lieutenant-Colonel to the Essex Brigade Volunteer Infantry Brigade, November 13th.

THE INDIAN MEDICAL SERVICE.

AN important article appeared in our contemporary, the *Army and Navy Gazette*, of November 2nd, on this subject, of which the following is a condensation. It is stated: The Secretary of State for India will be called upon at no distant date to give consideration to the reform of the Indian Medical Service. There is no doubt that the present arrangement of a civil and military branch thoroughly interchangeable has been the cause of much dissatisfaction... owing to the advancement of officers who have spent a considerable portion of their service in lucrative civil appointments to military administrative positions, to the prejudice and occa-

eternally supersession of medical officers who have passed the greater part, if not all, their service in military employment. Already we hear that a memorial is about to be forwarded to the Secretary of State for India, dealing with the defects of the existing system, and pointing out how improvements can be effected. It may be assumed that local officers must be employed with Indian troops, but if so, it should be a separate sanitary branch under the Principal Medical Officer of Her Majesty's Forces in India, with an ample cadre, so that he may not be obliged to rely on officers who are in civil employ as a reserve. This incessant bickering about medical officers from military to civil, and civil to military, berths, cannot but be a source of irritation to commanding officers of native corps, not to speak of the unfortunate Sepoy who has thrust on him a constant change of doctors. In short, the present organisation of the Indian Medical Service is utterly indefensible from a sanitary standpoint. If reform of a strict separation into two branches were carried out, officers should be called upon to elect for military or civil duties. Military rank and titles, and the wearing of uniforms, should be abolished in the civil branch. It must be clearly understood that under any system of reconstruction British soldiers in India must always be treated by officers of the British Medical Service. In two Lord Salisbury's minutes a "distinct civil medical service for India" was independent of the army. It is a well known regulation that officers of the Staff Corps after ten years in civil employ are no longer allowed to return to military duty. Why should a similar rule not be made applicable to the Indian Medical Service? Urgency of reform is our only plea for pointing out its defects.

Hearing on the above an able letter, signed "L.M.S.," lately appeared in the *Indian Pioneer*, pointing out that the principal medical officers of the Presidencies, and almost all the brigade-surgeons, are ex-civilians. "Indeed," it says, "to such an anomalous pass have matters come that the chances of military promotion are much better for men in civil than for those in military employment. The Surgeon General with the Government of India is a civilian, his promotions are naturally civil, his knowledge of the military surgeon and his work is very limited, he honestly thinks he is putting forward the best men, a promotion board is a necessity."

From other communications we have received there can be no doubt that several grievous cases of supersession in promotion of the military by the civil employ branch have lately accrued; such a system cannot go on, and calls loudly for speedy and effective reform.

BRIGADE-SURGEON-LIEUTENANT-COLONEL J. H. REYNOLDS, V.C. On November 11th Brigade-Surgeon-Lieutenant-Colonel J. H. Reynolds, V.C., was entertained at dinner by the officers of the Army Medical Staff at Shorncliffe, previous to his departure on leave pending retirement from the service. After the toast of "The Queen" had been drunk, Surgeon-Major Twiss, A.M.B., proposed "The Health of Brigade-Surgeon-Lieutenant-Colonel Reynolds," who responded in appropriate and feeling terms.

ARMY MEDICAL REORGANISATION.

F.R.C.S. suggests that a strong consultative committee should be formed consisting of retired army medical officers of standing and experience, together with leading members of the civil medical profession and of the schools, to deliberate on the future of the Army Medical Department, and to lay the results before the new War Office. If the authorities rejected such advice and assistance, then the public would know where to fix responsibility in the future.

"If a reorganisation of the Army Medical Service is contemplated and carried out, it must be wholly on the responsibility of the War Office whether outside advice is accepted or not. We feel quite sure the Secretary of State for War is not above advice in such a matter, and it will be time enough to offer it when he asks for it, or when he divulges the changes, if any, contemplated. We cannot for a moment believe any radical changes will be sprung upon the department or the profession; that would be a blunder. Due warning will be given."

CIRCULARS "OFFICIALLY" ADDRESSED.

Now how often have we complained that when official circulars are passed round in the district in which he serves, all the other heads, including the Army Service and Ordnance, are addressed as "officer commanding," while he is "medical officer in charge." At the same time he has more men under his "command" than several of them so addressed.

"Two reasons operate against his being addressed like the others: first, use and want of the term, 'in charge'; and, secondly, the fear that someone might have (officially) a fit should the term 'command' be addressed to ('only') a medical officer."

DISABILITIES OF THE ARMY MEDICAL SERVICE.

ROYAL COMMISSION writes: You were correct in a recent article as to the two chief grievances under which army medical officers labour. 1. The social grievance. Competition naturally draws our recruits from a mixed community, some successful candidates may not be so socially desirable as others. Men of that sort in regiments are usually quietly got rid of, but it is next to impossible in the medical service. Such men are largely the cause of garrison antagonism and club blackballing. 2. Indian service. In support of your contention, I submit the consolidated pay of a junior officer at home is £200 annually, or £20 a month, equal to 400 rupees a month at present exchange. The same officer in India draws £170 rupees a month, or £17 10s. sterling. This decrease is in the face of a marked increase in the pay of all other ranks while serving in India. To live as a gentleman in India, and to provide against frequent moves, 400 rupees a month is required as a minimum. It remains to be true, the complete autonomy of the Medical Staff and Medical Staff Corps is threatened, and a reversion to a regimental system spoken of. The former is the real goal of our hopes, the latter brought disaster in the Crimea and elsewhere. We want the undivided support of the profession and schools to defend us. What we require

is: (1) Recruits who are gentlemen; (2) make service in India tolerable; (3) preserve our autonomy; (4) give us field training; (5) make us a Royal corps.

MEDICO-LEGAL AND MEDICO-ETHICAL.

ACTION AGAINST A GLASGOW DOCTOR.

IN the Glasgow Sheriff Court on November 11th an action was brought by Michael McGinley, Castle More, co. Donegal, Ireland, who claimed £200 from James Stuart, M.D., 3, Eastpark Terrace, Maryhill, Pursuer, according to the report in the *Glasgow Evening News*, in his condemnation, stated that on May 11th he became ill, and a doctor was called in and pronounced him to be suffering from measles and bronchitis, and for these troubles he treated him for several days. The defender became aware that pursuer was lying ill, and although he knew, or ought to have known, of the nature of pursuer's illness, and that another competent doctor was attending pursuer, and in breach of professional etiquette, reported to the sanitary authorities that pursuer was suffering from small-pox, and the sanitary authorities caused pursuer to be removed to Knightwood Hospital in the small pox and fever van, where he was put into the small pox ward. Pursuer afterwards became infected with fever, and he was forced to remain in the hospital until he recovered. His health had been completely shattered, and it was unlikely that he would be able to work at his employment again. Sheriff Guthrie decided that pursuer's condemnation was irrelevant, and dismissed the case, finding pursuer liable in expenses.

In a note, his lordship says that pursuer did not aver malice and want of probable cause. He (pursuer) wished to infer that because the Infectious Diseases Notification Act of 1889 imposed a penalty upon certain persons, including every medical practitioner attending or called in to visit the patient, who failed to give notice that certain persons were suffering from infectious diseases, no one else was entitled or bound to give notice to and set the sanitary authority in motion in regard to such a patient. It must, however, be remembered that the Act of 1889 was only an improvement upon statutory enactments that had been in force since 1867. He did not doubt that medical men might act improperly in such matters, as well as unskillfully, for they were only human, and the pursuer possibly was not far from suggesting such a case, truly or otherwise. But actions of damages were not to be remitted to proof from bare suggestions. There was a further question—namely, whether the damage was not too remote. It was not clear that an informer in good faith, or even a medical man who was called upon to give a certificate to the local authority, ought to be held responsible if a local authority have, in the due exercise of its statutory powers, got a man removed to hospital while not suffering from any infectious disease, and he should there be infected by fever or small-pox. The sheriff added that he should be sorry if anything he said should suggest that he thought no action lay against a medical man who ultroneously obtruded himself upon a patient and upon the local authority for the sake of the small statutory fee, and thereby caused damage to the patient and a slight loss to a brother practitioner.

ACTION FOR SLANDER.

MANCHESTER ASSIZES.—NISI PRIUS COURT.
(Before Mr. Justice COLLINS and a Special Jury.)
BROOKS v. EATOUGH.

THIS was an action to recover damages for alleged slander. Mr. McCall, Q.C., and Mr. Acton appeared for the plaintiff, Samuel John Brooks; and Mr. Sheo, Q.C., and Mr. Byrne for Robert Eatough, the defendant. The parties are both medical men in practice.

Mr. McCall stated, according to the report in the *Manchester Courier*, that the plaintiff bought a practice at Moseley five or six years ago, and engaged the defendant as an assistant. The practice was a successful one, and the defendant was, on his own suggestion, taken into partnership. In 1894 Mr. Healey was introduced as a third partner. By the terms of the partnership deed each party was to attend upon his own patients, and to assist with regard to the patients of the others only when asked to do so. Disagreements took place between the parties, and a dissolution of the partnership was suggested. Mr. Brooks was unable to agree to this, and Mr. Eatough and Mr. Healey instituted an action in the Chancery Court for the dissolution of the partnership. The matter was, by consent, referred to an arbitrator, who investigated certain charges made by Mr. Eatough and Mr. Healey against Mr. Brooks. In the result the arbitrator found that the charges were not true. In July of the present year the defendant went to a lady who had been attended in her confinement by the plaintiff, and, it was alleged, made certain statements to her, in the presence of another lady, reflecting upon the professional skill and the moral character of Mr. Brooks. These statements were, Mr. Brooks said, absolutely slanderous, and he had greatly suffered in his reputation and business in consequence. He did not desire, however, to make any money out of this action, and if the defendant would now withdraw the statement he had made and apologise, and indemnify him against the costs which had been incurred, there would be an end of the matter. Mr. Eatough pleaded, first, that if he uttered the slander complained of it was spoken on a privileged occasion. Then he submitted that, whether there was slander or not, whether it was spoken under circumstances that prevented it being actionable or not, the plaintiff and himself agreed to refer that among other questions to the arbitrator, and that the arbitrator had dealt with the matter, and that, therefore, it had been taken away from the jurisdiction of these courts. He did not plead justification. In his cross-examination by Mr. McCall, Q.C., Mr. Eatough characterised the evidence of the lady to whom the slanderous statements were alleged to have been made as wholly false. He made the same remark with regard to the evidence of the second lady who was present on the occasion. He denied that he made any reflections upon the moral character of the plaintiff. All he had done was to state that rumours were current as to the relationship between the plaintiff and his servant, and that he ought, not only in his own interest, but also in the interests of the partnership, to take steps to disprove them.

The Judge, in summing up, said he was clearly of opinion that this was not one of the matters which had been referred by agreement to the arbitrator, and that the arbitrator had nothing whatever to do with this point. If the jury accepted the story of the plaintiff's witnesses, then the defendant's story, which the reader is spoken of, if it was spoken at all, was not privileged. The jury, after a short consultation, found for the plaintiff, and awarded him £500 damages. Judgment was given for that amount, with costs.

MONEY TENDERS INVITED.

With reference to the money tendered, addressed to the medical practitioners in the paper by several of whom our opinion has been solicited, we may note that comment, other than surprise that the proprietors of the establishment in question should have ventured to transmit such a message to members of the medical profession, is unnecessary. Need we add that any member thereof who would think of recommending thereto would be justly deemed to have departed from the honourable traditions of the profession.

"74, Withnell Road, South Shore, Blackpool.

"November 5th, 1895.

"Sir, Having become the purchaser and proprietor of the Hydro-pathic Hotel situated at South Shore, it is my intention to offer to medical practitioners residing in the district of South Shore, the privilege of daily attendance at the hotel, and being accommodated with a room for consultation and surgery, if required, such as has been used by Dr. Kingsbury. It must be distinctly understood that this arrangement does not preclude any of the business of the establishment from consulting any other medical man they may wish to.

"An early tender is requested.—I am, Sir, your obedient servant,

"SAM. HORROCKS."

MEDICAL FEES AT INQUESTS.

A. C. writes to complain that after giving evidence at the coroner's court he is informed that, as medical officer to the local cottage hospital, he is not entitled to any fee, and that from the possession he holds in connection with it he is excluded from receiving remuneration by Section 22 of the Coroners Act, 1887. Our correspondent asks: "Was the coroner within his rights in withholding my fee?"

"* On referring to the section of the Act above-mentioned, our correspondent will find that when a person dies in a public hospital or infirmary, whether supported by endowments or voluntary subscriptions, and upon whom an inquest is held, then the medical officer whose duty it was to attend such person is not entitled to receive any fee or remuneration for making post-mortem examinations or giving evidence at the inquest; and should the coroner by inadvertence pay such fees, he will be surcharged by the County Council as making an illegal payment, contrary to Act of Parliament. We quite agree with our correspondent that the law on this matter should be altered, but until this is done we should not advise him to sue the coroner, or to refuse to give evidence. It should not be forgotten that all witnesses summoned on behalf of the Crown can be compelled to give evidence, fee or no fee, or run the risk of fine or imprisonment for contempt of court.

DECEASED MEDICAL MAN'S PRACTICE.

A County Surgeon wishes to know if the trustees of a medical man can employ an assistant under bond till the son is qualified and able to take the practice. If not, can they sell the practice under bond to resell after a given number of years?

"* Executors or trustees have no power, in the absence of an express provision in the will, to carry on their testator's business, and doing so would render them personally liable for any loss occasioned thereby. Subject to this (and to any provisions contained in the will) we see no reason why a duly qualified medical practitioner should not be employed (under bond) to preserve the practice until the testator's son is duly qualified. We think it would be found impracticable to find a purchaser willing to become bound to resell after a given period; apart from the fact that such a repurchase might not be authorised by the testator's will.

DIPLOMAS AND MEDICAL ETHICS.

M. R.—Before proceeding to comment on the essential points of our correspondent's communication, we deem it right to remark that if he had chosen to undergo the ordeal of the L.R.C.P. Lond. examination he would, we opine, have refrained from characterising its title as (in quite his own words) "insignificant" when compared with the "magical" one of M.D. Such injudicious, uncalled-for comparisons are professionally impolitic and ill-judged, even if in accordance with fact, for it is not the possession of such a degree which dignifies the recipient, but his life action that reflects lustre thereon.

In reply to his special query relative to B., we may note that although corresponding with A. and C. in regard to the alleged unethical pressure of their late assistant, B., we apprehend that A. is de facto in a better position, as, while wishing to pay due respect to the recommendation by a friend, he should in engaging him have treated it as a matter of business, and insisted on the customary restrictive bond; the omission to do this has not only injuriously affected himself but his brother C. also, the latter having been deceived by B.'s statement that he had signed a bond with A.

If the allegations against B. fairly represent the facts, he will, we take it, find it more than difficult to establish a successful practice in view of his professional proscription, in relation to which we would,

under the exceptional circumstances, courteously remind the neighbouring practitioners that, be the conduct of the proscribed medical man what it may, none would be morally justified in a case of acute disease, in which delay would be dangerous, in refusing to give assistance.

MIDWIFERY PRISONERS CALLS.

H. H. P. writes: A. and B. are two friendly practitioners in the same place. A. is sent for without any previous warning by the husband for his wife's confinement. A. is out professionally for several hours, and the messenger is told at the house to send for B. B. goes to see the patient, and has to remain with her the whole night. The next morning A. calls and sees the patient (after everything is over and done with), and after wards goes and thanks B. for seeing to the case for him, and goes on attending the case, because he was first sent for. B., on that ground, hands the case over to A. The patient was a stranger to both A. and B. The husband simply went for the best known practitioner, who has been much longer in the place than B. Was B. entitled to keep the patient?

"* The principle enunciated in the appended rule is that by which A. and B. in the above case should be guided, to which may be added the following part of the succeeding rule: "When a practitioner is called upon by the assistant or servant of another to attend to an accident or other emergency in a family to whom both are equally strangers, the former is not entitled to take charge of the case throughout, but should act and be remunerated in conformity with Rule 7, and resign the case. When a practitioner is called in, or otherwise requested, to attend at an accouchement for another, and completes the delivery, or is detained for a considerable time, he is entitled by custom to one half of the fee," etc. *Ethical Code*, 4th edition, chap. II, sec. 5, rules 11 and 12.

MIDWIFERY ENGAGEMENTS.

T. A. writes that he was engaged by one B. to attend his wife at her confinement. At the time his wife was taken ill, B. called in another medical man who happened to be passing. T. A. asked for payment of his fee of two guineas as arranged, and his request not being complied with, proceedings were taken in the County Court to recover the amount.

At the trial B. denied the engagement. The Judge, however, was satisfied after hearing the evidence that such engagement was made, but stated that pecuniary damages had not been proved, and asked if our correspondent could quote any legal authority for damages having been obtained in similar cases. Our correspondent now requests assistance on this point.

"* We can only say that when this question was discussed in the *BRITISH MEDICAL JOURNAL* on a former occasion, a correspondent writing from Ilfracombe referred to a case in which he was engaged by letter (nothing turns on the point of the letters, and medical assistance was not required; he recovered his fee after declining to compromise by accepting half). Again, in the *BRITISH MEDICAL JOURNAL* of November 25th, 1894, allusion is made to a case then recently heard at the County Court of Newtownards, County Down, in which a fee was recovered under similar circumstances. The facts were not in this instance in dispute, but it appeared that after the doctor had made arrangements to be within call, when the time came another medical man was called in by the defendant. We cannot give any reference to law reports of these cases. They were probably not published.

A. AND B. (BIRMINGHAM).—The exact nature of the appointment held by A. is too vaguely noted to enable us to express a definite opinion thereon; should it, however, in any degree embody the principle of the so-called medical aid associations, we would counsel B. to decline the suggested partnership.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF OXFORD.

BOTH the examinations in the Michaelmas term for the degree of Bachelor of Medicine will commence at 10 A.M. in the Examination Schools on Friday, December 6th. The secretary to the Board of Studies will receive the names of candidates, either by letter or personally, at his office in the Clarendon Buildings at any time not later than 10 A.M. on Friday, November 22nd. The forms issued for this purpose can be had at the secretary's office. Names will be received as late as noon on December 22nd on payment of a special fee of 2 guineas. The statutable fees (Organic Chemistry and Materia Medica) fee each; the remaining subjects at 1s. 6d.; must accompany the entry form.

UNIVERSITY OF CAMBRIDGE.

DEGREES.—Professor T. W. Bridge, of Mason College, Birmingham, has been approved for the degree of Doctor of Science. Mr. H. R. Sedgwick, M.A., of Clare College, was on November 7th admitted to the degrees of M.B. and B.C.

UNIVERSITY OF DUBLIN.

IRISH GRADUATES AND FORTH-LAW MEDICAL OFFICERS. Mr. LUCKY, the historian, who is a candidate for the vacant Parliamentary seat for the University of Dublin, has sent the following reply

* *BRITISH MEDICAL JOURNAL*, March 10th, 1894.

to a letter addressed to him by Professor Windie, Dean of the Medical Faculty of Queen's College, Birmingham. Professor Windie, who wrote as an educator, drew Mr. Lecky's attention to the grievances of the Poor-law medical officers in Ireland, to certain disadvantages attending the present regulations of the Army Medical Service, and to the exclusive rules of certain hospitals in England:

[REPLY.]

28, Onslow Gardens, S.W.

November 6th, 1905.

DEAR PROFESSOR WINDIE.—It would be very unpardonable of me if I did not take a deep interest in the Irish Medical School, for there is certainly no other profession in Ireland which has produced during the present century so many men who have justly won a European reputation, and it is, I am afraid, only too true that a profession which cannot appear prominently on platforms and in Parliament is apt to be neglected by politicians. Should I be elected to Parliament I would consider it my duty to look carefully into any grievances under which Irish doctors may suffer, and to use any influence my position might give me to have them redressed. The regulations of English hospitals are, of course, not within the competence of Parliament, but any disabilities or disadvantages under which Irish doctors suffer, and from which English doctors are exempt, ought, if possible, to be remedied. I should be glad if I could do anything to further the work. I may also add that I shall do everything in my power to support any measure which may have the effect of improving the condition of the Irish Poor-law medical officers, and I shall also use every effort to have any legitimate grounds of dissatisfaction with present arrangements which may exist amongst the members of the Army Medical Staff removed. Believe me, yours truly,

W. E. H. LECKY.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The following gentlemen passed the First Professional Examination in Anatomy and Physiology for the diploma of Fellow at a meeting of the Board of Examiners on Monday, November 14th:

H. B. Angus, L.R.C.P.Lond., M.R.C.S.Eng., of the University of Durham College of Medicine; A. E. H. Finch, L.R.C.P.Lond., M.R.C.S.Eng., and H. T. A. Aveline, L.R.C.P.Lond., M.R.C.S.Eng., of University College, Bristol; R. Forsyth, M.B. B.Sc., of Queen's College, Belfast, and Owens College, Manchester; J. F. Johnson, of Yorkshire College, Leeds; H. A. Bruce, of Toronto University; and H. H. C. Dent, of Mason College, Birmingham, and St. Bartholomew's Hospital.

Thirteen gentlemen were referred for six months.

Tuesday, November 15th:

A. Felling, M.B. Lond., L.R.C.P.Lond., M.R.C.S.Eng., and F. Mannington, of Middlesex Hospital; R. E. Newton, M.B., M.S.Glasg., L.R.C.P.Lond., M.R.C.S.Eng., of Glasgow University and St. Bartholomew's Hospital; J. Batterby, of St. Mungo's College, Glasgow; J. Mooney, of Owens College, Manchester; J. M. G. Swinburn, of Westminster Hospital; P. E. Trevelyan, L.R.C.P.Lond., M.R.C.S.Eng., of Guy's Hospital; and Ewan R. Frazer, of London Hospital and Oxford University.

Twelve gentlemen were referred for six months.

Wednesday, November 16th:

E. G. Arnold, L.R.C.P.Lond., M.R.C.S.Eng., of St. Thomas's Hospital and Durham University; Cyril Wain, L.R.C.P.Lond., M.R.C.S.Eng., and R. M. Gowie, of King's College, London; H. W. Bruce, W. T. Milton, F.R. Bachelors, of Guy's Hospital; T. C. L. Jones, W. J. Harding, and E. G. Morland, of St. Bartholomew's Hospital; J. E. P. Palmer, of London Hospital; R. C. B. Wall, of London Hospital and Oxford University.

Nine gentlemen were referred for six months.

The following are the arrangements for the Final Fellowship, for which 42 gentlemen have entered their names:

Monday, 15th. Written Examination, 1.30 to 5.30 P.M., at Examination Hall.

Tuesday, 19th. Clinical Examination, 2.30 to about 5.30 P.M., at Examination Hall.

Wednesday, 20th. Operations, 1.30 to about 4 P.M., at Examination Hall.

Thursday, 21st. Surgical Anatomy, 2 to 4 P.M., at Examination Hall.

Friday, 22nd. Verbal Examination, 5 to 9.15 P.M., at Royal College of Surgeons.

Candidates will be required to attend on each of the above-mentioned days.

and 2.4 in Wolverhampton. The 106 deaths from diphtheria in the thirty-three towns included 24 in London and 4 in Wolverhampton. One fatal case of small-pox was registered in London and 1 in West Ham, but not one in any other of the thirty-three large towns. The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital, which had been 179, 184, and 181 at the end of the three preceding weeks, had further declined to 74 on Saturday last, November 12th. 14 new cases were admitted during the week, against 7, 14, and 25 in the three preceding weeks. There were 2,247 scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last, against 2,225, 2,231 and 2,311 at the end of the three preceding weeks; 340 new cases were admitted during the week, against 241, 290, and 210 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday last, November 12th, 702 births and 617 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 18.9 and 20.5 per 1,000 in the two preceding weeks, further rose to 21.4 last week, but was 0.7 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 10.9 in Greenock to 29.2 in Perth. The zymotic death-rates in these towns averaged 2.7 per 1,000, the highest rates being recorded in Perth and Greenock. The 292 deaths registered in Glasgow included 8 from scarlet fever, 3 from diphtheria, 12 from whooping-cough, and 3 from "fever." Two fatal cases of diphtheria were recorded in Edinburgh, and 2 in Leith.

METROPOLITAN ASYLUMS BOARD.

At the ordinary fortnightly meeting, held on November 10th, the returns showed that 732 patients suffering from "fever" had been admitted during the fortnight. During the same period 2,251 "fever" notifications were received; thus it would appear that about one-third of the cases are being isolated in hospital. 1,100 patients remained under treatment in the fever hospitals, an increase of 2 upon the previous report. This, however, is no index of the prevalence of fever, for the hospitals are practically full, there being at the time of the report 20 beds available for scarlet fever patients and only five for those suffering from diphtheria. There were 1,135 notifications of scarlet fever during the fortnight, an increase of 2 upon the number received in the preceding two weeks. It would thus appear that the seasonal decline in the prevalence is rather late, the highest point in the curve of the mortality from scarlet fever usually occurring about the middle of October. The number of beds occupied by diphtheria patients was 22, there having been but little change in this respect during the past few weeks; in fact, that number about represents the total of the beds available for the purpose. It is proposed to equal about 200 with the enlargement and reconstruction in permanent form of the North-Eastern Hospital.

NEWTON ABBOT WORKHOUSE INFIRMARY.

DR. CULROSS, the medical officer, has placed the quarterly report of the state of the workhouse before his Board. The report is pleasant reading after the sad revelations that drew the attention of the whole Kingdom to this house; but, though much has been done, very much remains to be done. The plans for the new infirmary seem to be well progressing in the official pigeon-holes at Whitehall (to our certain knowledge they have been there for over six months). When the new buildings are erected many of the existing defects will be remedied, but Dr. Culross draws the attention of his Board to the grave defects in the receiving wards, which he states to be "totally unfit for their purpose," and continues: "No care as provision for dealing with cases on their very entry is inadequate, all the care that may be taken in the other departments of the house may be rendered futile." He then points to the necessity of ward and nursing appliances, unsuitability of the children's nursery; all matters requiring serious consideration. One proposition, also, and one that has the most chance of the idea that the workhouse infirmary is a place of discipline for the worthless, and not also a place of treatment for the sick.

DANGEROUS OR INJURIOUS TO HEALTH.

THERE can be little doubt that when the authors of the Public Health Act of 1875, following the language of previous sanitary and Nuisance Removal Acts, defined a nuisance as a thing or condition of things injurious to health, they had in view not merely those in which past or present injury could be proved, but, as in every procedure, those in which all experience and analogy point to the certainty or probability of such a result under actual circumstances, or that the insertion of the additional word "dangerous" into the corresponding section of the London Act of 1891 was intended rather to remove any ambiguity attaching to former Acts than to extend its provisions and penalties to cases hitherto, and beyond the area of the metropolitan bill, to be exempt from the control of the law, in fact an interpretation of its own words given by the High Court of Parliament, in like manner as the Local Government Board explained the phrase "without proper lodging and accommodation," and the Justice of the Queen's Bench, disposed of the absurd suggestion of "prejudice to the purchaser." Until such authoritative declaration is established, legal authority will continue to diminish the preventive value of the Public Health Act, especially in the case of water supplies. The chemical composition of water, though not always an absolute indication of its purity, may leave no shadow of a doubt as to its direct contamination with sewage, and we know that many persons, at any rate if they have acquired a certain habit, may drink such water for years without any evident injury, but that should the sewage in question receive an accession of enteric, dysentery, or typhoid excreta, the outbreak of the disease among those using the water is inevitable.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns, including London, 4,220 births and 4,492 deaths were registered during the week ending Saturday, November 12th. The annual rate of mortality in these towns, which had increased from 19.1 to 21.9 per 1,000 in the three preceding weeks, further rose to 22.1 last week. The rates in the several towns ranged from 12.3 in Croydon, 14.7 in Huddersfield, and 16.1 in Wykehead to 29.5 in Salford, 31.4 in Wolverhampton, and 32.3 in Blackburn and in Liverpool. In the thirty-two provincial towns the mean death-rate was 22.7 per 1,000, and exceeded by 1.5 the rate recorded in London, which was 21.2 per 1,000. The zymotic death-rate in the thirty-three towns averaged 2.0 per 1,000; in London the rate was equal to 2.3 per 1,000, and corresponded with the mean rate in the thirty-two provincial towns, among which the highest zymotic rates were recorded in Salford, Wolverhampton, and Blackburn. Measles caused a death-rate of 1.9 in Liverpool and in Salford, 2.5 in Oldham, and 10.6 in Blackburn; whooping-cough of 2.0 in Cardiff, and "fever" of 1.2 in Salford, 1.5 in Oldham,

A case of this kind occurred recently at Epping, where the medical officer of health, Dr. Fowler, applied for an order to close a well, the water of which was shown by the county analyst to contain no fewer than 164 grains of solids to the gallon, including 14 grains of chlorine, with a like excess of ammonia, nitrates, etc. The owner, however, dismissed the case on the ground that thirty persons living, as the defendant alleged, drank the water for five years with only four deaths; it had not proved injurious to them, and that contamination was impossible at a depth of 12 feet. Certainly organic matter pervading down to a depth of 12 feet of unmineralized "living" earth would undergo complete sterilization through the action of the bacteria of the upper soil, and if the sewage, which was manifestly present, reached the well by lateral percolation through some of gravel or fissures in the chalk it would undergo no purification whatever. We are not told the ages of the people or the causes of the deaths, but if typhoid fever, which is not unknown in Essex, were introduced into the village a serious outbreak might be expected. The argument for the defence would be equally applicable to the storage of barrels of gunpowder or petroleum. In shops as showing the absence of danger until an explosion took place.

THE YARMOUTH GUARDIANS AND PAUPER LUNACY FEES.

At a recent meeting of this Board the question of fees paid for the certification of pauper lunatics was introduced by the Vice-Chairman, who considered *ten. ed.* quite enough to pay for each of these certificates. The Chairman explained that the Board could not rule this question, as the amount depended on the acting magistrate, who was empowered to order any reasonable fee to be paid. The Vice-Chairman advocated appealing to the magistrates as a body to order a fee not exceeding *ten. ed.* The Chairman said was not likely to be entertained by the magistrates, who did not act as a body in reference to these cases. Notwithstanding this explanation, the Vice-Chairman, supported by a lady guardian and one or two others, still pressed his opposition to paying more than *ten. ed.* It may save this gentleman and his supporters further trouble if we inform them that the amount of the fee to be paid for the medical certificate required before a pauper lunatic can be sent to an asylum depends on what is stated by the chairman, on the magistrate who sits in the case, and that the Board of Guardians have nothing whatever to do with the question beyond that of paying the fee after the magistrate has awarded it. This is so clearly defined by the last Lunacy Act that we are surprised to hear of any Board of Guardians wasting time by discussing the question.

AN ISOLATION HOSPITAL FOR GRAN.

We notice with satisfaction that a very generous gift has been made by the senior medical practitioner in Gran, Dr. Mackenzie, to the Burgh of Gran. For some time past the necessity for an isolation hospital has been fully recognized by the local authorities. Plans have been prepared, and they have been approved by the Local Government Board for Scotland, but the inevitable question of cost cropped up. The building will at present consist of a central or administrative block and one pavilion, two wards, with accommodation in all for six beds, the remaining pavilion to be erected at a later date, and it is estimated that this will cost about £1,000. Dr. Mackenzie, realizing the necessity for such a hospital, has now made a gift to the Burgh of £1,000. The gift is unfettered by any conditions further than that during his lifetime he receives 5 per cent. as interest on the capital, and he reserves to himself the right of expending this interest upon the building, either in its extension or upon its improvements in any way that may seem best to him.

THE ALLEGED PREMATURE DISCHARGE OF PATIENTS FROM FEVER HOSPITALS.

An interesting report has been presented to the Metropolitan Asylums Board by a sub-committee appointed to make inquiries with reference to outbreaks of illness alleged to have been caused by the premature discharge of patients from the Board's fever hospitals. The cases in which this is alleged to have occurred were in the proportion of 1 to every 250 discharges, but many of these cases did not develop until so long a period after the return of previous cases from the hospital as to render it impossible that the discharged patient could have been the cause of the infection of the second case. In their investigations the Committee inquired into the various methods of disinfection adopted by the various local sanitary authorities, as it seemed not improbable that in some cases the apparent reintroduction of infection might be due to the bringing into use again of imperfectly disinfected articles of clothing which had been stored away during the patient's absence in the hospital. The results of these investigations are somewhat disquieting, as showing the very imperfect methods adopted by several of the vestries. The subject was reported on by the medical officer of the London County Council not long ago. The Committee report: (1) That in Chelsea there was no steam disinfectant until the end of 1893, and that, from the time such disinfectant was used, "these so-called return cases have been of very rare occurrence." (2) That in Fulham the disinfection is, or was in December, 1894, entrusted to a contractor, who keeps the bedding in a chamber for from ten to twenty minutes only; (3) That in Kensington disinfection by dry heat is applied; (4) that in Lambeth the utmost heat attained is 200 degrees; (5) that in Islington disinfection is entrusted to a contractor.

The average stay in hospital of the patients under the care of the Asylums Board appears to have been during the year 1894, seventy days for small fever cases, and forty-two days for diphtheria cases, while, from the replies received from various fever hospitals in the provinces and in Scotland, it appears that the average stay in those places ranged from thirty-seven to seventy-two days in the cases of scarlet fever patients, and from eighteen to forty-two days in the cases of diphtheria patients.

In an appendix a summary is given of the regulations in force at the various hospitals under the management of the Board, to ensure that all patients are free from infection at the time of their discharge, regulations which if faithfully carried out ought, in our opinion, to be sufficient, being certainly considerably more stringent than the precautions commonly taken in private practice.

In conclusion, the Committee report: (a) That there is no evidence to show that any appreciable number of patients admitted to the Board's hospitals during the past two years have contracted infection from patients previously discharged therefrom. That there is reason to believe that at the so-called "return" cases some have been due to the reintroduction of infection into households, owing to the disturbance of insufficiently disinfected clothes, etc., left at home and stored away during two patients' stay in hospital. (b) That it is desirable that those sanitary authorities in the metropolitan district who have not yet provided themselves with steam disinfectors should be urged to do so with the least possible delay; and, further, that the authorities who still entrust the work of disinfection to contractors should be advised to discontinue the practice, and to have work carried out by responsible officials.

PUBLIC VACCINATION.

A CONSTANT READER.—A public vaccinator who deputes his work as such to an unqualified assistant has no right to hold the post, and cannot legally sign a certificate of successful vaccination performed under such conditions, neither is he entitled to the payment of fees by his Board of Guardians; and, the facts being known to the Local Government Board Inspector would entail loss of award.

A NEW INFECTIOUS DISEASES HOSPITAL FOR BELFAST.

At the last monthly meeting of the Belfast City Council the following resolution of the Public Health Committee was approved of.

Your Committee again affirm their opinion that the time has arrived when a thoroughly equipped hospital for the isolation and treatment of citizens suffering from infectious diseases should be provided for the city of Belfast, and that such hospital should consist of not less than sixty beds at an annual cost of £30 per bed; and your Committee are also of opinion that the Notification of Infectious Diseases Act should be adopted.

There is now a prospect of this too long delayed scheme being carried into effect. As to the pressing need of a new infectious diseases hospital for Belfast there can be no second opinion. The chairman of the Public Health Committee, Alderman Graham, M.D., and the superintendent medical officer of health, Dr. Whitaker, have been active in pressing the matter upon the attention of the corporation.

PARISH COUNCIL (SCOTLAND).—It is competent for the parish council to maintain A. in the position of parochial medical officer in the parish of X, although non-resident, and in spite of the fact that another medical man has become resident there. The Local Government Board will have no ground for action, and cannot refuse to sanction the appointment, unless it is alleged that the parsons in X are not properly attended to. At the same time the parish council, in making the appointment, are bound to take into consideration the advantage of having a resident medical officer.

INDIA AND THE COLONIES.

INDIA.

WATERBORNE CHOLERA.—The *Englishman* reports that Shahabad was last year, as in the previous year, the most unhealthy of all the districts in the Patna Division. The first appearance of cholera is traced to the Kumbh mela at Allahabad. It first broke out in the Sadar subdivision, and then in a village near to Sasaram, and during the heat of May and June in an epidemic form throughout the district. Everything was done by the local officers and district and local boards that could be done in the way of affording medical aid, disinfecting, and introducing sanitary reforms, but with little visible effect. The disease tenaciously held its ground, as in Gaya, until September, committing greater ravages than any other district in the division. It is at first sight disappointing to find that in the town of Arrah, notwithstanding the introduction of a filtered water supply, there was an unusually severe outbreak. This is explained by the fact that, owing to the use of coarse sand in the filter beds, the water for the first few months was much discoloured, and the people on this account objected to take it. This, however, was subsequently remedied, and the purity of the water is now undisputed. The collector adds that inquiries showed that in part of the town where people overcame their prejudices and used the filtered water cholera was less prevalent than elsewhere. On the subject of the prevalence of cholera throughout the district, the Civil Surgeon remarks as follows: "There can be no doubt that the great spread of cholera was due in great part to the defective water supply of the district and from the pollution of drinking water. The corpses of those who die from cholera are very often not properly burnt, and in many instances are thrown into rivers and irrigation reservoirs without any attempt at cremation whatever. Such occurrences were brought to my notice at Delhi, and were by me reported to the magistrates, with a request that such practices should, if possible, be put a stop to." The heavy mortality from fever is ascribed, as in Gaya and elsewhere, to the unusual character of the season. The improvement in vaccination operations is also favourably noticed by the collector.

THE ANTHROPOMETRIC SYSTEM.—It is stated that the Government of India considers it essential that the anthropometric system for the identification of criminals should be extended to all parts of India, including the feudatory States, and it has requested that "arrangements" may, if possible, be made for police officers from the Bengal Presidency to visit the gaols of those States under its control and to measure criminals.

We learn that the number of gentlemen attending the present practical class on chemical pathology in the Chemical Pathology Laboratory at University College, London, recently described in these pages, is seven.

MEDICAL NEWS.

A FURTHER article on the late Professor Ludwig will be contributed to *Science Progress* by Dr. Asher, of Bern, in collaboration with Professor Kronecker. It will be published in the December number.

MR. A. E. MAY, Public Vaccinator of the Forest Hill District of the Lewisham Union, has received for the tenth time the Government grant for efficient vaccination in his district.

THE first meeting of the Zoological Society of London for scientific business will be held at 3, Hanover Square on Tuesday, November 19th, at 8.30 p.m. Among the contributions will be one by Mr. Swale Vincent, M.B.Lond., on the Suprarenal Bodies in Fishes.

THE personal estate of the late Surgeon-General Sir Thomas Longmore, C.B., has been valued at £19,650 2s. 3d. By the will, which bears the date May 11th, 1885, his widow, Dame Mary Rosalie Helen Longmore, is appointed sole executrix, and to her the testator bequeaths all his real and personal estate whatsoever.

THE opening by the Duke of Devonshire of the new Home (the "Passmore Edwards House") at the Colony of the National Society for the Employment of Epileptics at Chalfont St. Peter, which was postponed from August 7th last, has now been fixed to take place on November 26th, at 2.45 p.m.

THE Christmas course of lectures adapted to a juvenile auditory will be delivered at the Royal Institution by Professor J. G. McKendrick, of Glasgow. The subject will be Sound, Hearing, and Speech. The lectures, which will be illustrated by experiments, will be delivered at 3 p.m. on December 28th, 31st, and January 2nd, 4th, 7th, and 9th.

THE ROYAL ACADEMY OF MEDICINE IN IRELAND.—Dr. James Little, President of the Royal Academy of Medicine in Ireland, will entertain his Excellency the Lord Lieutenant at dinner in the Royal College of Physicians on Thursday, November 28th. We understand that Dr. Bennett, Professor of Surgery in the Medical School of Trinity College, will be a candidate for the Presidency of the Academy in 1897.

THE annual dinner of the staff and past and present students of the Dental Hospital of London will be held on Saturday, November 30th, at the Café Royal, under the presidency of Mr. Frederick Canton. We are requested to state that any gentlemen now or formerly connected with the hospital or school who may not have received a private intimation are invited to communicate with the Dean, at the Dental Hospital, 40, Leicester Square, should they desire to attend.

THE next general meeting of the Medico-Psychological Association of Great Britain and Ireland will be held at 11, Chandos Street, Cavendish Square, on Thursday, November 21st, 1895, under the presidency of Dr. David Nicholson, at 4 o'clock. Dr. W. Gilmore Ellis will read a paper on Latah. Dr. Morrison will read a paper entitled Short Notes of a few cases of Epilepsy affecting Special Nerves and their associated Mental State. The members will dine together at the Café Royal at 6.30 p.m.

THE CHOLERA.—The cases of cholera in Egypt since October 11th are stated officially to number 591, of which 443 were fatal. The epidemic is reported to be confined to the district south of Lake Menzalah, mainly along the canal Bahr es Sughair, between the Lake and Mansurah. The infected district has been placed under four English doctors, with a staff of inspectors, to examine every possible boat on the canal and on the Nile between Damietta and Benha, and as far as possible to report the movements of all travellers.

HOSPITAL SUNDAY FUND.—A special meeting of the Council of the Hospital Sunday Fund was held at the Mansion House on November 7th to distribute the additional awards for the year. The report of the Committee of Distribution stated that the Lord Mayor having received additional contributions, amounting to £16,000, since the distribution made to the hospitals and dispensaries about three months ago, a special meeting of the Committee was convened to consider

the desirability of making a second distribution this year, when it was unanimously resolved to recommend the Council to sanction the disposal of that sum amongst the various institutions, calculated on the bases previously approved. The usual 5 per cent. would be reserved for surgical appliances.

At the monthly meeting of the Association of Registered Medical Women, on November 5th, Mrs. Garrett Anderson was in the chair and thirty-four members were present. Miss Julia Cock, M.D., showed a case of the disease known as "sprue" or tropical diarrhoea. The patient, a young woman, had spent seven years in India. Miss Cock dwelt upon the diagnostic points which separate sprue from chronic dysentery, malaria, pernicious anemia, and tuberculous ulceration of the intestines. The girl is now in the New Hospital for Women, and Miss Cock will be glad to show the case to any members of the profession interested in tropical diseases.

AN EXHIBITION OF NURSING APPLIANCES.—The Trained Nurses' Club and Midwives Institute has during the past week been exhibiting a collection of appliances which its members have found useful in their work. A short inspection of the exhibits suffices to show what an amount of thought and ingenuity is being devoted to the elaboration of those accessories by which the work of nursing is facilitated. At the same time it is impossible not to see, from the very nature of the objects which are shown, how largely the modern nurse is becoming the medical man's assistant. In sterilising his instruments, in preparing his dressings, in making ready for his operations, and in fact in doing the after-dressing of the case, the well-trained nurse is evidently prepared to act as house-surgeon to the operator in private practice. There is no doubt both a good and a bad side to all this. To the operator it offers immense facilities, but the general practitioner will probably regard his fascinating substitute with mingled feelings.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION.—The autumn meeting of this Association was held at the Monaco Restaurant on November 12th, the President, Dr. Phillips-Conn (Reading), in the chair. There was a large attendance of members, including Sir Walter Foster, M.P., Inspector-General Lloyd, R.N., Dr. Stewart (Clifton), and Dr. Cagney and Surgeon-Major Carte, the honorary secretaries. The President drew attention to the severe loss the Association had sustained by the death of their late Chairman of Council, Sir Thomas Crawford, K.O.B. Dr. Abraham and Dr. Gilbert Smith proposed a vote of condolence with the family of Sir Thomas Crawford, which was seconded by Dr. Crespi and passed unanimously. The autumn dinner of the Association took place the same evening, when the guests of the evening were the Lord Chief Justice of England and Mr. Justice Mathews. Amongst other distinguished guests present were the Right Hon. Lord Battersea, the Right Rev. the Bishop of Newport and Meneira, Sir F. Osborne, Bart., Mr. Yarrow, Dr. Nicolson (Broadmoor), Dr. Frederick Roberts, Mr. Thomas Smith, Dr. Robert Anderson, and Dr. Stephen Mackenzie.

SAFE PLACES FOR POOR CHILDREN.—The Metropolitan Public Gardens Association, of which the Earl of Meath appears to be the moving spirit, continues its good work of providing open spaces for the use of the dwellers in London. The importance of this work can hardly be appreciated by those who do not remember the time when—except the few parks which then existed—there were no open spaces whatever for the use of the people and the people's children. No one will deny the great benefit which the parks are to the atmosphere of London, but they are too far off from many homes, and, unfortunately, are in many cases, under too lax a supervision to make them safe places for little children. The gardens, however, which have during recent years been opened in almost every part—planted and in summer filled with flowers and provided with seats and caretakers—are safe refuges close at home, and are of the utmost service as breathing places for the little ones. The opening of some of the school playgrounds on Saturday afternoons, under proper supervision, is another matter which has been taken in hand by the Association very much to the advantage of the younger portion of the community.

THE MAYOR OF CAMBRIDGE.—After the meeting of the Cambridge Medical Society on November 1st, a complimentary dinner was given to Mr. Hyde Hills, Mayor of Cambridge, and lately President of the Society. The chair was taken by Professor Clifford Allbutt, who, in proposing the health of the guest, referred to the exemplary manner in which he had carried out both municipal and social work. Mr. Hills, in responding, after thanking the members of the Society for the honour they had done him, dwelt upon the desirability of medical men taking an interest in municipal work which they could do with advantage to themselves and to the community. Amongst those present were Sir George Humphry, Dr. Holden, Vice-President of the Society, Dr. A. Anningson, Mr. Hough, Mr. Balding, Mr. Wherry, and Dr. Laurence Humphry.

MEDICAL VACANCIES.

The following vacancies are announced:

BATH GENERAL OR ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer; unmarried. Salary, £100 per annum, with board and apartments in the hospital. Applications to Frederick W. George, Registrar and Secretary, before November 25th.

BLACKBURN AND EAST LANCASHIRE INFIRMARY.—Junior House-Surgeon. Salary, £50 per annum, with board, washing, lodging, etc. Applications to Nathan A. Smith, Secretary, Infirmary Office, 10, Richmond Terrace, Blackburn, by November 27th.

BRADFORD INFIRMARY.—Dispensary Surgeon; doubly qualified; unmarried. Salary, £100 per annum, with board and residence. Applications, endorsed "Dispensary Surgeon," to William Haw, Secretary, by November 28th.

CHelsea, BROMPTON, AND BELGRAVE DISPENSARY, 41, Sloane Square, Chelsea, S.W.—Honorary Surgeon. Applications to the Secretary by November 21st.

CLIFTON DISPENSARY, Doury Square, Bristol.—Resident Medical Officer; not exceeding 30 years of age; doubly qualified. Salary, beginning at £150 a year, increasing annually by £10 to £200, with furnished rooms only. Applications to R. C. Macfie, 42, Royal York Crescent, Clifton, Bristol, before November 2nd.

DENBIGHSHIRE INFIRMARY, Denbigh.—House-Surgeon; must be duly qualified to practise medicine and surgery, and be conversant with the Welsh language. Salary, £50 per annum, with board, residence, and washing. Applications and testimonials to W. Vaughan Jones, Secretary, by December 2nd.

GENERAL HOSPITAL, Birmingham.—Assistant House-Surgeon. Appointment for six months. No salary, but residence, board, and washing provided. Applications to Howard J. Collins, House Governor, by November 8th.

GENERAL INFIRMARY, Northampton.—House-Surgeon; doubly qualified; unmarried, and not under 25 years of age. Salary, £25 per annum, with furnished apartments, board, attendance, and washing. The Assistant House-Surgeon is a candidate, and, if appointed, the Committee will proceed with the election of Assistant House-Surgeon. Salary, £50 per annum, with furnished apartments, board, and attendance. Applications to the Secretary by November 23rd.

GENERAL INFIRMARY AT GLOUCESTER AND THE GLOUCESTER-SHIRE EYE INSTITUTION.—House-Surgeon; doubly qualified. Salary, £50 per annum, with board, residence, and washing. The Assistant House-Surgeon is a candidate for the post, and, if elected, the office of Assistant House-Surgeon will be vacant. Candidates must be doubly qualified. Board, residence, and washing provided. Applications to the Secretary by November 24th.

HANTS COUNTY ASYLUM.—Third Assistant Medical Officer; doubly qualified; age must not exceed 25 years, and must be unmarried. Salary, £50 per annum, increasing to £100 after twelve months' service, with furnished apartments, board, washing, and attendance. Applications, endorsed "Application for Appointment of Medical Officer," to the Committee of Visitors, Knowle, Farnham, by November 25th.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—Resident Medical Officer. Salary, £50 per annum, with board, lodging, and washing. Applications to W. Reid, Secretary, before November 20th.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Bloomsbury.—House-Surgeon to out-patients; unmarried. Appointment for six months but eligible for a second term. Salary, £5 guineas. Applications to the Secretary by November 2nd.

HOSPITAL FOR WOMEN, 140, Regent Square.—Assistant House-Physician; non-resident (appointment for three months) and Assistant Physician. Applications to the Secretary by November 25th.

LESTER INFIRMARY.—Temporary Ophthalmic Surgeon (temporary). Applications to the Secretary, 21, Finner Lane, Leicester, by November 25th.

LONDON HOSPITAL, Whitechapel, E.—Dental Surgeon. Applications to the Governor by November 30th.

MANCHESTER ROYAL INFIRMARY.—Assistant Medical Officer at the Mosaic Fever Hospital; unmarried. Appointment for twelve months. Salary, £100 per annum, with board and residence. Applications to the Chairman of the Board, Royal Infirmary, Manchester, by November 30th.

NEW HOSPITAL FOR WOMEN, 144, Euston Road.—Two Qualified Medical Women as House-Surgeons. Applications to Margaret M. Bagster, Secretary, by November 27th.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney Road, Shore-ditch, N.E.—House-Physician; doubly qualified. Appointment for six months; at the expiration of this term he will be required, if eligible, to serve as House-Surgeon for a further period of six months. Salary as House-Physician at the rate of £200, and as House-Surgeon at the rate of £250 per annum. Junior House-Physician for six months; doubly qualified. No salary, but board and lodging, including washing, provided. Applications to the Secretary, 37, Clarendon Lane, E.C., by December 1st.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William Street, West Strand, W.C.—Clinical Assistant. Applications to T. Beattie-Campbell, Secretary, by November 30th.

SCARBOROUGH HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Appointment for six months. Salary, £50 per annum, with board and lodging. Stimulants and washing not provided. Applications to the Honorary Secretary by November 24th.

TIVERTON INFIRMARY AND DISPENSARY.—House-Surgeon and Dispenser; registered and unmarried. Salary, £50 per annum, with lodging, attendance, fire, and lights. Applications to Arthur Fisher, Honorary Secretary, by November 24th.

VICTORIA UNIVERSITY, Manchester.—External Examiner in Pharmacology and Therapeutics and in Surgery. Appointment for three years. Applications to Alfred T. Beattie, Registrar, by November 30th.

WEST NORFOLK AND LYNN HOSPITAL, King's Lynn.—House-Surgeon. Salary, £50 per annum, rising £20 annually to £70, with board, residence, and washing. Applications to the Secretary by November 2nd.

MEDICAL APPOINTMENTS.

ANDERSON, Mr. D. A., appointed Medical Officer for the Cuckfield District of the Teesdale Union.

ARCHER, H. R., M.D. Lond., L.R.C.P., reappointed Medical Officer for the No. 1 District of the Royston Union.

BECKEN, G. H. E., M.R.C.S., L.R.C.P., appointed House-Physician to the Queen's Hospital, Birmingham.

BLACKFORD, Mr., appointed Medical Officer for the Cradley District of the Stourbridge Union, *vice* W. H. Thompson, M.D. Dur., J. R.C.P. Edin.

BRUCE, Mr. J., appointed First Assistant Medical Officer to the Garden Road Workhouse and the Infirmary of the Parish of Camberwell.

CHERRINER, William McEntire, M.R.C.S., L.R.C.P. Lond., appointed Medical Officer for the Third Sedgeley District of the Dudley Union.

COLLINS, E. Treacher, F.R.C.S., appointed Assistant Surgeon to the Royal London Ophthalmic Hospital, Moorfields, E.C.

GILFILLAN, S. J., M.A., M.B., C.M. Edin., appointed Second Assistant Medical Officer to the Norfolk County Asylum, Thorpe.

GREY, T. Campbell, F.R.C.S. Eng., L.R.C.P. Lond., appointed Lecturer on Ambulance and Nursing to the Hunst County Council.

HAINES, A. W., B.Sc., L.S.A., appointed House-Surgeon to the Queen's Hospital, Birmingham.

HAYWARD, J. W., M.R.C.S. Eng., L.S.A., appointed Medical Officer of Health to the Whitstable Urban District Council.

HOGG, Mr., appointed Medical Officer for the Shardlow District of the Shardlow Union, *vice* Charles Harwood, M.D., L.M.S. Edin.

JONES, Mr. C. A., appointed Second Assistant Medical Officer to the Gordon Road Workhouse and the Infirmary of the Parish of Camberwell.

LEES, E. Leonard, M.D., C.M. Edin., M.R.C.S., appointed Physician to the Hospital for Sick Children and Women, Bristol, *vice* W. Barrett Low, M.D., resigned.

LUKE, T. D., M.B., B.Ch.I., appointed Medical Officer to the parish of Durness, Sutherlandshire.

McCOMBE, E., L.R.C.P., L.R.C.S.I., appointed Medical Officer for the No. 2 District of the Royston Union.

MACKENZIE, W. R., L.R.C.P., L.R.C.S. Edin., reappointed Medical Officer of Health to the Alfofts Urban District Council.

MACLEOD, Charles Gordon, M.B. Edin., appointed Honorary Assistant Ophthalmic Surgeon, Sydney Hospital, New South Wales.

MATTHEWS, Mr. T. G., appointed Medical Officer for the Sixth District of the Mansfield Union.

MEISTER, F. G., M.R.C.S., L.R.C.P., appointed Obstetric and Ophthalmic House-Surgeon to the Queen's Hospital, Birmingham.

MOORE, Frederick P., L.S.A., appointed Medical Officer of Health to the Urmoston Urban District Council.

NUNN, P. W. G., L.R.C.P. Lond., M.R.C.S. Eng., appointed Medical Officer of Health to the Popesdown Urban District Council.

PATCH, H. H. L., M.R.C.S. Eng., L.R.C.P. Lond., appointed Medical Officer for the Chudleigh District of the Newton Abbot Union, *vice* F. C. W. Housell, B.A. Camb., M.R.C.S. Eng.

PENNY, John, M.B., C.M., B.Sc. (Public Health) Edin., appointed Resident Medical Officer to the Manchester Hospital for Consumption and Diseases of the Throat, *vice* N. F. Edwards, M.B., B.Sc. Edin., resigned.

RENNIE, A. M.B., B.C. Camb., appointed Medical Officer of Health for the Beher and The Dittons Urban District Council.

DIARY FOR NEXT WEEK.

MONDAY.

LONDON POST-GRADUATE COURSE, London Throat Hospital, Great Portland Street, 8 P.M.—Dr. Edward Wenkes: Tinnitus and Vertigo.

TUESDAY.

LONDON POST GRADUATE COURSE, Bethlem Royal Hospital, 2 P.M.—Dr. Percy Smith: General Paralysis of the Insane.
THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M., Lecture at 4.

PATHOLOGICAL SOCIETY OF LONDON, 20, Hanover Square, W., 5.30 P.M.—Mr. Edmunds: Cystic Accessory Thyroid. Mr. Targitt: Classification of Sarcomata connected with Bladder. Mr. Barrett: Acute Tuberculosis of Spleen removed by Operation. Dr. Rundle: Primary Epithelioma of Ureter. Mr. D'Arcy Power: Diffuse Lipoma of Hand and Fingers. Card Specimens by Dr. Claremont and Dr. Walsham.

WEDNESDAY.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. G. Y. Dias: On Hemiplegia.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 3 P.M.—Lecture by Mr. Beavor.

ROYAL METEOROLOGICAL SOCIETY, 25, Great George Street, Westminster, 5.30 P.M.

WEST LONDON HOSPITAL, Hammersmith, W., 5 P.M.—Mr. Swinford Edwards: Rectal Surgery (Post-Graduate Course).

NORTH-WEST LONDON CLINICAL SOCIETY, North-West London Hospital, 5.30 P.M.—Clinical Cases.

ROYAL MICROSCOPICAL SOCIETY, 20, Hanover Square, W., 5 P.M.

THURSDAY.

LONDON POST-GRADUATE COURSE, Hospital for the Paralyzed and Epileptic, Queen Square, 2 P.M.—Dr. Tooth: Hemiplegia. Hospital for Sick Children, Great Ormond Street, 3.30 P.M.—Mr. Donald Gunn: Ocular Evidence of Hereditary Syphilis. Central London Sick Asylum, Cleveland Street, 5.30 P.M.—Mr. Thomas Bryant: Cases in the Wards.

SOCIETY OF ANAESTHETISTS, 20, Hanover Square, W., 8.30 P.M.—Introductory Address by the President. Mr. Rickard Lloyd: Six Hours' Administration of Chloroform in a Case of Cumulative Poisoning by Hypodermic Injection of Strichnine.

HARTMAN SOCIETY OF LONDON, 8.30 P.M.—Mr. Juler: Pathology and Treatment of Some Forms of Irritis.

FRIDAY.

LONDON POST-GRADUATE COURSE, Bacteriological Laboratory, King's College, 3 to 5 P.M.—Professor Grookshank: Lecture: Erysipelas and Suppuration. Practical Work: Cultivations of Streptococci.

CLINICAL SOCIETY OF LONDON, 20, Hanover Square, W., 5.30 P.M.—Medical Evening: Mr. W. A. Lane: Cases of Excision of the Temporomaxillary Joint in Children. Dr. Harry Campbell: (1) A case of Premature Puberty and (2) a case of Rheumatoid Arthritis confined to the elbow-joints. Dr. B. Hingston Fox: A case of Meningocele. Mr. J. H. Morgan: (1) Double Penis and Malformation of Genitals; (2) Harelip and Cleft Palate, with Deformity of Ear and Face and with Auricular Appendage. Dr. Buzzard: A case of Charcot's Joint Disease. Dr. Colman: Mother and Child with Idiopathic Muscular Atrophy. Mr. O. Paget (introduced by Mr. B. Paget): A case of Myositis Ossificans. Mr. H. H. Clutton: Two cases of Deficiency of Tibia. Mr. G. S. Wallace: A case of Ligature of the Femoral Artery and Vein for Secondary Hemorrhage. Dr. E. K. Witter: A case of Myeloma. Mr. W. H. Battle: A Modified Operation for Removal of the Vermiform Appendix. Dr. Martin: A case of Ligature of both External Iliac Arteries by the Transperitoneal Method. Mr. H. Paterson: A case of Extensive Skin Grafting.

SATURDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 11 A.M.—Dr. Percy Smith: Puerperal and Lactational Insanity.

BIRTHS, MARRIAGES, AND DEATHS.

Charge for inserting announcements of Births, Marriages, and Deaths is 6d. which can be paid by post office order or stamps with 11 notices not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

BIRCHMAN.—At Dunrobin, Elie, on November 15th, the wife of Philip G. Birchman, M.B., of a daughter.

HARTWELL.—On November 2nd, at Irwell, Wotton-under-Edge, Gloucester, the wife of John Hartwell, L.R.C.P., of a daughter.

HOLDEN.—On November 14th, at 10, Castle Hill, Reading, the wife of G. H. R. Holden, M.A., M.D., of a son.

HUGHES.—At Hanover House, M.C., on November 15th, the wife of David Hughes, M.A., M.B., of a son.

MORRIS.—On October 31st, at Southwold, near Caernarvon, South Wales, the wife of Sylvanus Morris, M.B., of a daughter.

MARRIAGES.

JAMES BOWLING.—On November 15th, at St. John's, Kingston-on-Thames, by the Rev. Arnold J. H. Smith, M.A., Harold J. James, M.B., Eng., L.R.C.P., and Lucy Adelaide (Miss), only daughter of the late Rev. Canon Bowling, Rector of Froton, Somerset, and Mrs. Bowling, of London.

DEATHS.

MOCK.—November 14th, 1895, at 1, Portester House, W., Frederick Cook, M.D., Edin., M.R.C.P. Lond., aged 61.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDNIGHT POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non-delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate before and with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUERIES.

W. H. P. asks for a statement of experience as to the value of lachnanthes in chest affections.

NEMO asks: What is the best work to read up for technical lectures in first aid, etc., ordered by the County Council?

W. P. W. would feel obliged if anyone could tell him of a school or institution where a boy, aged 16, of weak intellect could be received. He is not an idiot, is very small for his age, an orphan, and when of age will be entitled to some £130, though at present he has nothing.

M. D. writes: About eighteen months ago there was in the BRITISH MEDICAL JOURNAL an advertisement of a bath towel, made of tape, so arranged that the edges of the tape formed the rubbing surface. I obtained a sample, but unfortunately have lost the address. Can any reader assist me?

INQUIRER asks (1) to be recommended to an establishment where a bath or baths could be obtained (for a case of muscular rheumatism) in London. (2) He inquires, also, whether a person suffering from delirium tremens is responsible, in the eyes of the law, for any act of homicide or other personal damage, or would he be termed of unsound mind?

M. B. Abert asks for suggestions as to the treatment of a case of diarrhoea in a lady of 30 years of age. It commenced after the birth of a child twenty-five years ago, and has been going on more or less since. The stools are watery, never formed, the mucus, and average two or six daily. Three or four times a year she has an aggravated attack, lasting two or three weeks, accompanied by severe abdominal pain and tenderness, the stools numbering eight or nine daily, and causing considerable prostration. Appetite remains good. All ordinary remedies have, I believe, been tried without much effect. Ail. bole seems to be of some use. Her temperament is somewhat nervous.

HOME FOR INEBRIATE WOMAN.

R. G. W. asks whether there is any home for inebriates where a woman could be received for about £1 ls. a week.

* * We cannot recommend any individual practitioner or institution. Probably a list of cheap homes could be seen at the office of the local Charity Organisation Society.

RESTRICTIVE REGULATIONS OF THE ROYAL COLLEGE OF PHYSICIANS AND SURGEONS.—I should be glad to be informed what would be the effect of the College of Physicians forbidding the Members to practise medicine or surgery for fees in courts of law. The text of these regulations declares nearly all the posts in rural districts to be being taken by the Members of the College, and the other regulations seem to be intended to secure the rights of a citizen, which may not be quite moral.

PERMATE TENTS.

MR. B. would feel much obliged if anyone who has had practical experience in the use of permute tents could give him some particulars on the following points: (1) If they are easy and safe to erect, dismantle, and pack; (2) as it is stated that they are not so strong as they would be if they were made of canvas, what is their condition at the end of one or two years' use; (3) as it is the design of the permute tents to be used in wet weather, and (4) are they liable to catch fire and on roads which are much higher at the centre than the sides?

SPECIAL TREATMENT OF PELVIC CAVITIES.

H. G. A. asks how he can obtain the most important communications which have been published dealing with the treatment of the pelvic cavities by means of the permute tents, or if he has any literature of value dealing with the subject.

* * Very little advance has been made in this subject since the pub-

lection in 1887 of Mr. Godlee's Lectures on the Surgical Treatment of Pulmonary Cavities. The latest papers of interest relating to this branch of surgery are by Dandridge in the *Journal of Surgery*, February, 1894, and by Krause in the *Reinhold's Clinical Pathology*, No. 16, 1895. We have not met with any recent monographs on the subject. The former might be obtained from Cassell and Co., and the latter probably from Williams and Norgate, Henrietta Street.

HOME FOR LEPROSY.

M.D. would be glad to know of any home or hospital where a gentleman of limited means affected with leprosy could be received as a permanent, and on what terms?

"A." We are not aware that any institution exists in this country wherein patients suffering from leprosy or other disfiguring chronic complaints can be permanently maintained. Those who can afford it have to live in their own houses or cottages with special nurses, others have to drift ultimately to the Poor-law infirmaries, for although the general hospitals are glad to receive a case of this kind for a month or two, they cannot be kept for an indefinite time. In point of fact, there is a serious want of such an establishment for these unfortunate sufferers.

SIR RICHARD QUAIN'S ADDRESS.

Dr. G. P. HURRY (Strawberry Hill) writes: The profession must be very much obliged to Sir R. Quain for his splendid address. This is the kind of talk one wants to hear. But is the venerable baronet quite right about the Board of Health? My friend gives me as the date of the General Board of Health. Or might there have been a Board of Health (not general) before this?

"A." We have called Sir Richard Quain's attention to this point and he writes that the Board of 1852 had relation to the invasion of cholera. The General Board of Health arose from it subsequently, and took cognisance of various professional matters. Sir Benjamin Hall was President of this Board in 1854-5.

CANCER IN THE SCILLY ISLES AND JERSEY.

MR. ROGER WILLIAMS, F.R.C.S. (Preston), writes: It is alleged that in this country cancer is specially prone to be prevalent in low-lying districts, traversed by or contiguous to rivers that seasonally flood the adjacent lands. In favour of this opinion there is much to be said, but the great majority of human habitations are thus situated, and, moreover, this theory offers no explanation as to why some low-lying districts have such a much higher cancer mortality than other low-lying districts equally exposed to floodings. Under these circumstances it appeared to me that light might be thrown on the subject if we had information as to the prevalence of cancer in small islands like those of Scilly, Jersey, and Guernsey, which are destitute of rivers that seasonally flood their banks. Therefore I lately wrote to Dr. Mackinn, the medical officer of health for the Scilly Isles, who has published recently an excellent account of their medical climatology, and he very obligingly furnished me with the following particulars. These show that both cancer and tubercle, especially phthisis, are fairly common in the Scilly Isles. During the last five years their population has averaged about 2,000; 5 deaths from cancer occurred during this period, which is equivalent to a mortality of 5 in 10,000 living. During the same period the English cancer mortality averaged about 4.5 per 10,000. It would thus appear that the prevalence of cancer in the Scilly Isles is somewhat less than it is on the mainland. I have been informed by a Jersey practitioner that cancer was very prevalent there, as well as in Guernsey; and I am desirous of making it known through the BRITISH MEDICAL JOURNAL that I shall feel exceedingly obliged to anyone who will be kind enough to furnish me with information on this interesting subject. Official returns, reports of medical officers of health, etc., would be exceptionally valuable; but even in the absence of definite statistical information the impressions of practitioners as to the prevalence of cancer in these islands would be of great service.

ANSWERS.

M. A. W.—If the different points named are to be covered by one book Whiteleggs's *Hygiene and Public Health* (Cassell, 7s. 6d.) would be suitable.

INQUIRY.—Our correspondent might apply to the National Health Society, 21, Berners Street, London, W., which will probably be able to arrange the lending of diagrams.

Dr. J. E. R.—The cheapest and most recent work is the series of articles republished in book form from the BRITISH MEDICAL JOURNAL entitled *The Truth about Vaccination*, by Ernest Hart, to be obtained of Messrs. Smith, Elder and Co., 15, Waterloo Place, S.W.

PARALLEL.—(1) and (2). It is contrary to the policy of the British Medical Association knowingly to elect homœopaths as practitioners as members. The matter was reported on by a Committee of the Council. At the meeting of the Council on July 14th, 1895, the report of this Committee was received and adopted and ordered to be circulated to the secretaries of the Branches. (3) The General Medical Council is specifically excluded from making any inquiry as to any system of medicine which a duly qualified medical man may choose to follow. (4) We are not acquainted with any work which gives a broad definition of what is meant by homœopathy. The definition would probably vary at different epochs. (5) We cannot undertake to explain the "intellectual processes necessary for the change from those views which a future homœopath must necessarily hold at the time of his final examination to those views which he must hold as a practising homœopath." It is one of those mysteries which no one but the authoress of a "problem novel" would attempt to penetrate.

W. P. M.B. writes: In answer to the query of "Rus," I would recommend firstly a strict regimen, namely, animal food once a day, green foods, cooked or as salads, to be partaken of freely, cured foods and sugar to be avoided; if any alcohol, even beer and wines of a similar nature. As medicaments: R. Hydrarg. subchlor. gr. 5; ext. gentianæ q. s. Ft. pil. sum. bis hebdom. h. s. R. Pulv. Carlsbad eff. (Kulnow's) 3ss vel 5j prima mens ex sign.

SUMNER-MASON H. FERGUSON, M.B., I.M.S. retired (Birmingham) recommends "Rus" to try a course of iodide of potassium or mercury alternating with quinine. If he has not already done so, as this treatment has been successful in similar cases.

THE TITLE OF "DR."

A CONSTANT READER.—The "L.S.A." is now a complete diploma, but does not entitle the holder to style himself "Dr."

TREATMENT OF PSORIASIS.

L.R.C.P., in answer to "J. F. D." in the BRITISH MEDICAL JOURNAL of November 9th, p. 1210, strongly recommends the thymal treatment, and refers him for guidance to an address given by Dr. Burton Branswell and published in the *Transactions of the Dermatological Society of Great Britain and Ireland*, 1894-95, vol. 1.

ELECTRICITY.

A MEMBER.—The form of battery used for household electric bell is not at all suitable for electric light. We should advise "Electricity" to purchase a small accumulator, which he could have charged up from the nearest central station whenever it runs down. The cost of such an installation need not exceed a few pounds, depending of course on the kind of lamp he wishes to light. We are assuming that he wishes for a small incandescent lamp only for surgical use.

NAIL BITING.

Dr. P. Z. HENNER (Berners Street, W.) writes: The most effective method I have found of eradicating this habit is to train the subject to attend to his nails, instead of with scissors and file, instead of doing so, as he imagines, with his teeth. The impulsion of the nail biter occurs scores of times a day. The subject must have a pair of suitable scissors and a file at hand in his pocket to cut away shreds of skin around the nails, and pare and smooth the nails at any moment of the day. By perseverance in this method I have cured several cases, one a man over 60 years of age, in whom the habit had lasted since childhood.

BOOKS ON MEDICINE AND SURGERY.

RUS IN URBE, who asks for a list of books by reading which a practitioner of fifteen years' standing may bring himself up to date on certain subjects, will probably find the following useful: 1. Medical diagnosis: *Clinical Diagnosis*, by Rudolf v. Jaksch, translated by James Cagney, M.D. Charles Griffin and Co. 1890. Pp. 388. *Clinical Medicine*, by Judson S. Burry, M.D. Charles Griffin and Co. 1891. Pp. 468. 2. A *Text-book of Pharmacology*, by T. Lauder Brunton, M.D. F.R.S. London: Macmillan and Co. 1891. 3. Surgical treatment: *The Science and Art of Surgery*, by Sir John Eric Erichsen. Tenth edition. London: Longmans, Green, and Co. 1895. 2 vols. about pp. 1,200 each.

DEGREES FOR LONDON STUDENTS.

LATE HOUSE-PHYSICIAN draws attention to an evil which has been pointed out many times before, that is, the hardship which falls upon men, and more especially upon London students, who find towards the end of their time of study, when perhaps they are feeling greatly drawn towards medicine, that they cannot obtain a medical degree without taking up again the subjects of the preliminary examinations. The hope has long been held out that this injustice would be remedied by the establishment in some form or other of a teaching university for London, and we would suggest that our correspondent and all others who feel aggrieved in the same way should put themselves in communication with the deans of their schools and the governing bodies of their colleges in order that pressure may be brought from every side to urge on reform. For years back almost every action of the press, both lay and medical, has insisted on this matter being dealt with in a comprehensive spirit.

NOTES, LETTERS, Etc.

THERE are said to be 1,294 medical practitioners in the United States who rejoice in the patronymic of Smith.

THE AIRD JOLLY FUND.

MR. GARRY SIMPSON, Treasurer (East Aclon, London, W.) acknowledges with thanks the following additional subscriptions:

	£	s.	d.
Mr. C. A. Ballance, F.R.C.S., London	...	2	2
Sir Edwin Saunders, F.R.C.S., Wimbledon	...	2	0
Dr. Beecham, Ealing	...	0	10
	...	6	

SANITATION IN CAWNPORE.

THE Upper India Chamber of Commerce held a meeting on August 28th to consider this matter. The chairman showed that last year there occurred 3,800 preventable deaths in the city and cantonments, and claimed that this meant a loss of nearly 25 lacs of rupees to the community. Arguing from this he submitted that the municipality would be justified in incurring almost any conceivable expenditure to reduce the mortality to a reasonable figure. The meeting resolved to address Government, requesting the election of a committee to consider the whole question, and suggesting the appointment of two new officials—namely, a paid vice-chairman of the Municipal Board, who should be an experienced sanitary engineer, and a medical officer of health, who should be a European, prepared to devote the whole or a greater part of his time to the duties of the office.

BRUSHING DIRTY CARPETS.

MRS. ENTWISLE AND KENTON write to us to say that their attention has been called to a paragraph in the BRITISH MEDICAL JOURNAL on the above subject, in which it is recommended that carpets should be brushed by an "American sweeper." As the largest European makers of carpet sweepers, they suggest that there is no reason why "American" sweepers especially should be purchased, when English sweepers can be obtained—sweepers which are in every respect more durable, reliable, and perfect in action than the great bulk of the imported ones.

LICENTIATES AND THE TITLE OF "DR."

DR. W. F. RICHARD (Putney) writes: Will you allow me to point out that a legal decision has been given upon the question of Licentiates of the College of Physicians styling themselves "Drs.," and that the decision has not been approved against or upset. It is published in the BRITISH MEDICAL JOURNAL of April 5th, 1895, as follows: "Mr. M. D. Makana was then charged with putting upon his door a plate announcing himself as 'Dr. Makana,' thereby implying that he was a Doctor of Medicine, when he was in reality only a Licentiate of the Royal College of Physicians. Evidence was given showing that this was a general practice, and the case was dismissed with costs." Before the Stipendiary Magistrate, Petty Sessions, Ystrad Rhondda.

MR. WILLIAM THOMAS, M.R.C.S., L.R.C.P., L.S.A., M.O.H. (Nottingham) writes: Since writing my previous letter to you upon the use of the title "Physician" and the prefix "Dr." by Licentiates of the Royal College of Physicians, I have received the following letter from the Edinburgh College:

"Royal College of Physicians, Edinburgh, November 4th, 1895. 'Dear Sir,—I have received your letter of the 2nd. In reply, I beg to inform you that the subject of which you write is under the consideration of a Committee of this College. The result of their deliberations cannot be available for some little time. Meanwhile, I may say that the College has never sanctioned the adoption by its Licentiates of designations other than those legitimately implied in the licence which it grants.—I am, etc.,

"W. THOMAS, Esq., L.R.C.P.Ed., etc. WILLIAM PHILIP."

I have looked carefully through the history and laws of the College of Physicians of Edinburgh, and nowhere therein can I find any clause relating to the word "physician" or "Licentiate" may call himself or be called through the word "physician" is frequently used in reference to each of them. Previous to the year 1860 this College only licensed men to practise medicine who had graduated in a University; and it was about the same time that the London College of Physicians created its new order of Licentiates; previous to that time all men licensed by these Colleges were entitled to be called physician, and were styled "Dr.," but from that time to this, the proper designation of such Licentiates has been the subject of perpetual squabbles both in and out of the press. Anything which can be done by our Association to bring a final decision will earn the gratitude of its members.

THE ROYAL COLLEGE OF PHYSICIANS IN IRELAND AND THE TITLE OF "DR."

J. J. A. R.—We believe that our correspondent is in error in supposing that the charter of the King's and Queen's College of Physicians in Ireland conferred upon its diplomates the title of "Dr.," and that he is mistaken also in believing that in an action between Trinity College, Dublin, and the College of Physicians the Court held that diplomates of that College were entitled to style themselves "Drs." The then Registrar of the College addressed to us a letter on this subject (published in the BRITISH MEDICAL JOURNAL of January 1895, p. 143), in which it is stated that the decision of the Master of the Rolls, in the action referred to, "was to the effect that the College of Physicians has not the power to grant the degree of 'Dr.' The Registrar stated further that by a resolution of the President and Fellows adopted on April 5th, 1886, the Registrar and Clerk of the College were instructed 'not to use the title of 'Dr.' in officially addressing any of its Licentiates, except in the case of those Licentiates who, having in addition a University degree of M.D. are by it legally entitled to be styled 'Doctor.' The following is a copy of a circular letter which the Registrar informed us sent to all inquiries:

Royal College of Physicians of Ireland, 6, Kildare Street, Dublin.

DEAR SIR,—In reply to your queries I beg to inform you that, in the opinion of the President and Fellows, a Fellow, Member, or Licentiate of this College is not entitled legally to call himself "Doctor" or to use the initials "M.D." in writing or being a Fellow, Member, or Licentiate as aforesaid.—I am, dear Sir, JOHN WILLIAM MOORE, B.A., M.D. (Dubl.), Fellow and Registrar.

CHURCH CATARETH.

THE REV. EDMUND INNESON (Vicar of St. Michael and All Angels, Westminster) writes: All who attend public worship will be grateful to you for your article upon heating and ventilating churches. When the former of these two points has to be considered, it is so all-absorbing to some persons that the latter is entirely overlooked or does not meet with the thought which it deserves.

We built this church ten years ago, and at the time of laying out our plans we gave careful and practical consideration to both of these very important questions, and so have succeeded in carrying them out so satisfactorily that your readers may like to know what we did. In a small room placed directly in front of the windows high up to let out the hot and exhausted air with its impurities, and put down below Grundy's hot air apparatus. We can then heat and ventilate at the same time, for each is the equivalent of a powerful stream of hot fresh air which we get in, that we can afford to open our upper windows even in very cold weather. The hot air which we receive into the church, rid the apparatus is perfectly pure having come to us from the outside, where we have placed it, and our exhaust is together with the heat from the gas-stoves and goes out at the chimney windows, and all this while a stream of fresh air is rising from below. This system of heating and ventilating churches is so satisfactory because it is so practical, and the principle of action is in accordance with the laws of Nature.

There is another point quite worth consideration, which I think is

much overlooked, and the effects of which are only contributed by this hot air method. The underground passages and gratings are so useful in summer to allow the ingress of cold fresh air, so they provide hot fresh air in winter. If, therefore, in summer the upper windows are opened, the cool fresh air entering the church and the apparatus will keep the building fresh without the necessity of opening the doors and lower windows, and thereby avoiding a draught. Hot-water pipes radiate their heat into the close air already in the church; they cannot provide fresh air.

THE VALUE OF A HEALTH DEPARTMENT.

When the Health Department of New York was organised on a scientific basis in 1886 the death rate was 35.04 per 1,000. In 1895 it had fallen to 29.31; in twenty years more the rate was further reduced to 26.25; in 1895 the rate was 23.22, and last year the lowest record was reached since 1814, namely, 21.05 per 1,000 inhabitants.

IRREDUCIBLE DISLOCATIONS OF THE SHOULDER.

DR. EDMOND SOUCHON, Professor of Anatomy and Clinical Surgery, Tulane University, New Orleans, U.S.A., is investigating the operative treatment of irreducible dislocations of the shoulder, recent or old, simple or complicated, and will be glad to have accounts of cases that have been operated on. He would also be grateful for records of cases of persistent or simulated aneurism whether operated on or not. Due credit will be given for any reports that may be sent him.

VARICOCELES AND THE SERVICES.

C. F. W. writes: In what way does a varicocele—excluding those very rare cases of excessively large varicoceles—incapacitate a man? I suppose nineteen men out of every twenty have a small varicocele, yet they do their work and live to a good old age, and never know that they are suffering—no, not suffering, that they are the subjects of this complaint, all important in the eyes of the Government, at any rate. Why, then, are young men wishing to enter one of the services compelled first to undergo an operation if they happen to have a varicocele? But what I object most to is that hospitals (we are constantly getting them at the one I am connected with) have to admit these fine, healthy, young lads, and board them for a fortnight or three weeks. If the Government will insist on observing this regulation, it ought in all fairness to pay the hospitals for the board of these cases. It is hardly fair to use subscribers' money to feed perfectly healthy young patients. As the regulations stand at present we can hardly refuse to take these cases in to enable them to enter the services.

RAPID DIAGNOSIS.

MR. ALBERT EHLMANN, M.R.C.S. Eng., etc. (Bitterne, near Southampton), writes with reference to a quotation from the *Westminster Gazette*, published under this heading in the BRITISH MEDICAL JOURNAL of October 5th, to say that Plarrer Kneipp, when receiving patients, though he smokes a big cigar, has a keenly qualified medical man who first endeavours to make a diagnosis. Though the examination is in most cases a very cursory one, yet most patients have previously consulted a medical man, of whom there were three or four in Wiesbaden who adopted Kneipp's methods. Mr. Ehlmann adds: I have seen the ointment, composed of ointment of honey, containing, I believe, vermouth, used in a case of optic atrophy. After its use the patient suffered the most intense pain. Of course, there was absolutely no improvement in the condition, but then nothing is looked upon as incurable in Wiesbaden.

PASTEUR FILTERS AND THE MADAGASCAR EXPEDITION.

W. D. writes: Staff-surgeon Kirker suggests in the BRITISH MEDICAL JOURNAL of October 19th that much of the fever present among the French troops in Madagascar was probably enteric, and that as these troops were doubtless furnished with Pasteur filters, the occurrence of the fever seems to point to its having been communicated otherwise than through the water. The same idea had occurred to me when I first read the announcements of the fact, and I applied direct to Paris for information. I have not been able to ascertain how much, if any, of the fever was enteric and how much malarial, but I have ascertained definitely that the troops on march had no filters at all. Pasteur filters were supplied to the whole of the transport ships, and troops arrived at Madagascar in good health. The incident therefore leaves the question of the waterborne origin of enteric fever in the same position as before.

FRIENDLY SOCIETIES AND THE MEDICAL PROFESSION.

M.D. and L.R.C.P. LOND. OF SOME STANDING writes: The profession in general will be greatly pleased at the step taken made by the Portsmouth medical practitioners in refusing such paltry payment for attendance upon the friendly members of the medical friendly societies. It would be as well if other towns would follow their example by inaugurating a medical union, surely four shillings per annum for each member is by no means regarded as excessive. The prevailing system evidently is being established by these societies, so that it behoves the profession to guard its interests by refusing not to accept such paltry remuneration as the societies offer, the medical men, as others, must live, which cannot be done upon such a low scale.

Another question engaging the profession at the present time is as to what it does to which they are not entitled, it does seem that it is the surgeons, many are not living up to the traditions of the College, and obeying its by-laws, which are clear, not allowing them to name themselves doctors upon their door-plates or cards. If their names were extended to the Royal College of Physicians of London, no doubt they would quickly hear from the Registrar that they were not acting in good faith, and have their attention drawn to the by-laws, which they are bound to obey.

A RUSSIAN CENTENARIAN.

According to the *Revue Russe* the word of an old man in the Dan is often visited by a good movement, whose age is given as 122. This patriarch, whose name is Andrei Avloupol, is a Cossack. He has been twice married, and has eight sons and three daughters living. Another son, who was three feet, died at three years of age at the age of 10. The number of his grandchildren and great-grandchildren is twenty-six.

PENALTIES FOR SPOOFIFICATION OF MILK

Dr. W. S. GORDON, MATTHEWS, in his annual report on the sanitary condition of the city of London, E. A. G. says the *London Journal*, the attention of the Commissioners of Sewers to the various kinds of offences that exist in the possible exposed for offences against the Public Health, the (what are) generally being represented by the legal professions; and the improvement and temporary laws imposed upon milkmen and small general traders, who are convicted of adulterate and fraudulent adulteration of their goods. He says: It is a common experience that a milkman may be fined and for adding half the quantity of water to his beer that a dairyman would add to his milk at the cost, perhaps, of a building fee. The practical inference to be drawn from these differences is that, whereas in the case of milk, a child or an invalid may be deprived of it to 50 per cent., and even more, of nourishment, certainly perhaps to the maintenance of human life, the publican who may add the same quantity of water to his beer, which in fact he does, and may be a blessing in disguise, is treated in large commands upon his pocket in the shape of fines, whilst the dairyman too often escapes with a nominal penalty. The explication of this may be that the publican is pursued by the restless activity of an Excise officer, aided by the best available licensed agent, whilst the milkman is prosecuted on a stipulated, and beaten way by local authorities, who frequently consider indictment as to the result. What a travesty upon justice! Mr. Matthews adds that in the City of London has not been deemed necessary to institute any prosecution, although some of the articles examined have been seriously near all London.

LETTERS, COMMUNICATIONS, ETC., have been received from :

(A) Mr. H. W. Attingham, London; Mr. G. E. Aldridge, Weston super-Mare; Professor T. McCall Anderson, Glasgow; Dr. J. Althaus, London; C. P. M. Althorp, M.B., Bradford; Dr. F. P. Atkinson, Salford; Dr. J. H. Abram, Liverpool; Mr. W. R. Ancrum, Gloucester; Dr. A. Alexander, London; C. Abbott, M.B., Bournemouth; A. M. S.; Anser. (AB) Mr. R. J. Brooks, Mossley; Mr. W. **SCALE OF CHARGES FOR ADVERTISEMENTS IN THE
BRITISH MEDICAL JOURNAL.**

Eight lines and under	400	200	200	200	4 0
Each additional line	100	50	50	50	0 0 6
A whole column	400	200	200	200	1 17 6
A page	100	50	50	50	6 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage stamps.

N.B.—It is against the rules of the Post Office to receive letters at

AN ADDRESS

ON

THE RELATIONS OF PHYSIOLOGY AND MEDICINE,

DELIVERED AT THE OPENING OF

THE SECTION OF PHYSIOLOGY,

At the Annual Meeting of the British Medical Association at London, July-August, 1895.

By DAVID FERRIER, M.D., F.R.S.,

Professor of Neuro-Pathology in King's College, and Physician to King's College Hospital.

THE programme before us is so interesting and varied that, if for no other reason, it would be out of place for me to occupy your time with many words by way of introduction; but besides this there is a rule, in which I gladly take refuge, which prescribes that the Presidents of the Sections shall practically limit their introductory addresses to the regulation fifteen minutes.

When I was asked to preside over this Section my first impulse, much as I appreciated the honour, was to decline, on the ground that at such an important meeting as this, almost international in character, this chair should be filled by a physiological specialist rather than by a clinician like myself; but on further consideration I thought that, without being regarded as a usurper, I might as a physician occupy this honourable post, if only by so doing to emphasise the intimate union between physiology and physic, which it is the object of this great Association to proclaim and encourage by establishing a special section for physiology.

In former days, and that not so long ago in the history of medicine, such an apology would have seemed quite unnecessary, for few, if any, would have been found prosecuting the study of physiology who were not also engaged in the actual practice of medicine or surgery. Things, however, have greatly changed. Owing mainly to the division of labour, which the progress of knowledge has rendered a necessity, physiology has become increasingly technical, and tended to separate itself more and more from medicine in its practical aspects. Hence there has grown up, more perhaps in other countries than in our own, a generation of physiologists who have little interest or sympathy with the practitioners of medicine; while we have still, and always have had, a class of practitioners who, though acknowledging physiology to be the institutes of medicine, do so in a purely academic sense, and say farewell to its problems and methods when once they have passed their examinations and engaged in the practical work of their profession. In both extremes there lies great danger to the best interests of the science of physiology and the science and practice of medicine.

Many of the most important discoveries in the history of physiology have been made by physicians or surgeons, who in the earlier years of their professional life, or in the leisure hours of busy practice, have found time to investigate vital problems, often to the uninitiated of apparently little practical value, but which have borne rich fruit in after-years. And it is highly desirable that this class of medical practitioner should survive and increase. The history of medicine, as Sir James Paget has forcibly shown in a recent address, has abundantly proved that the scientific spirit and the exact methods of the physiologist do not unfit a man for the practical work of his profession, or, to put it on a lower basis, diminish his prospects of success from a worldly point of view. To controvert the opposite opinion would seem almost a work of supererogation, were it not that there are still to be found many who think the so-called "practical man" is the best type of the medical profession.

It is customary to say that medicine is "applied physiology," and it would be very desirable if we could honestly say that this was the case. But the stock of physiological knowledge which we are able to apply effectively in the practice of medicine is infinitesimal as compared with our ignorance both of the intricate nature of vital processes and the means of regulating or controlling them. While in the diagnosis, treatment, and prevention of disease we apply to the best of our power such principles as may have been

scientifically evolved, or have only a foundation in empiricism, these are wholly insufficient to satisfy our requirements, and there are so many opprobria in every department of medicine that we hesitate to specify them for fear of proclaiming too loudly our poverty and impotence.

What we most need is new knowledge, and it is the great aim of scientific medicine to endeavour to arrive at a more exact knowledge of the functions of our organism, of the conditions which cause deviations from the normal standard, and of the methods for counteracting them. This is really physiology in its widest sense as much as the experimental work of the laboratory.

The aims and the methods of the clinician and physiologist are in many respects the same, and whether the facts are obtained by observation or created by experiment does not affect their value, provided they are dealt with on the same scientific principles. The work of the clinician is, for the most part indeed, of greater difficulty than that of the experimentalist. Instead of being able to select his conditions and vary his circumstances at will like the experimental physiologist, the clinician is usually confronted by a complex assemblage of phenomena, to unravel and analyse which demands the highest scientific acumen. And he who, in spite of these difficulties, succeeds in differentiating a group of related symptoms, and traces their connection with some definite lesion or morbid process, advances physiology, in my opinion, just as much as he who succeeds in solving a biological problem in the comparative simplicity and quiet of his laboratory. It rarely happens, however, that clinical research by itself is capable of arriving at that degree of certainty or completeness of explanation which the canons of inductive research demand, and but for the experimental method we might have to wait indefinitely, or in vain, for a solution of many of the problems which present themselves to the clinical inquirer.

The practice of medicine offers not infrequently rare conjunctions of symptoms, and valuable opportunities of research, too often wasted, which a little physiological training on the part of the practitioner might often have turned to good account; and the necessities of practical medicine have been the most fertile source of inspiration of physiological experiment. Much of what might otherwise have remained as vague surmise or, at most, plausible hypothesis, has been raised to the level of verified fact by well conceived and often simple physiological experiment. The experimental method is, as it were, the keystone of the arch; indispensable indeed to the security of the structure, the foundations of which, however, have been laid in clinical observation. Such has been the chief rôle of the experimental method in medicine; and on this ground alone it has proved its necessity to medical science, even if it cannot lay valid claim to being the sole origin of all the great discoveries of recent years.

In minute analysis of the vital processes the physiologist must necessarily diverge from the clinician, and devote his attention to the solution of problems which may seem to have little bearing on practical medicine, merely as a branch of biological science, and in the pursuit of truth for its own sake. But the whole history of science, physical as well as biological, has shown that every new fact finds in time its appropriate place in the great edifice of knowledge, and proves its necessity just as surely as any of those whose uses are more immediately apparent.

The inability to appreciate the value of a new truth is a measure of the depth of the individual's ignorance. How portentous this can be, and yet unassociated with becoming modesty, we have unfortunately too frequent illustration in the opposition which science in general, and physiological science in particular, has had, and has still to contend with. Though, as we have said, the physiologist, in the pursuit of his analysis, tends to separate himself farther and farther from the clinician, there is a danger of too great exclusiveness, and the risk is that in his syncretism he may fall into errors of generalisation which a knowledge of clinical medicine would tend to correct. This has often been urged by the clinician as a reproach against the experimentalist, and not in all cases without reason. The ultimate test of the applicability of a physiological generalisation, or principle, to man, must be its harmony with the facts of human physiology and clinical medicine. As against this, however, the

physiologist may retort, and with justice, that times without number experimental physiology has first opened the eyes of the clinician, and taught him to see clearly where all before was darkness and confusion.

In illustration of this one need only instance the comparative order which has established itself within recent years in the facts of cerebral pathology, which before the experimental methods were, for the most part, unintelligible, and apparently full of contradictions. But while in many—perhaps I ought to say most—departments of physiology the experimental method is the most powerful weapon of inductive elimination, there are problems in the investigation of which the clinical method is indispensable, not merely as a means of testing the applicability to man of the results of research on the lower animals, but as alone capable of yielding positive testimony on questions in which the evidence of experimental physiology is at best only inferential. It is enough in this relation merely to mention the many problems of neurology involving subjective conditions, such as the kinds and qualities of sensation which cannot be satisfactorily determined without appeal to the facts of clinical medicine. And, as Professor Pavlov has shown in his recent address on the relations of Physiology and Medicine,¹ the psychical factor cannot be neglected even in such apparently merely chemical problems as the phenomena of digestion. And in not a few instances the experiments of Nature, carefully investigated, have of themselves established facts of the utmost value, which experimental physiology has not succeeded in adding to.

Almost the whole of our knowledge of the so-called trophic influence of the anterior cornua on the muscles, has been arrived at by clinical observation on the symptoms of anterior poliomyelitis and progressive muscular atrophy in man; and on similar observations has been largely founded our knowledge of the segmental grouping of muscles in the spinal cord, which has only been rendered more precise by experimental research.

On clinical research primarily, and to a large extent solely, rests much of what we know respecting the paths of degeneration in the nerve centres inaccessible to the experimentalist, but often within the reach of the morbid processes of disease. The physiology of the ductless glands—namely, the thyroid, the suprarenal capsule, and the pituitary body—rests, for the most part, on clinical research, which was the first to establish the probable relation between the dystrophies of myxœdema or cachexia strumipriva, Addison's disease, and acromegaly, and abnormal conditions of these glands respectively. This, especially in the case of the thyroid, has been verified, and practical applications indicated by the valuable experiments of Schiff, Horsley, and others, but the actual methods of one of the most brilliant therapeutic triumphs of the present day, and the addition of a new chapter to the physiology of nutrition, have been largely due to the work of Murray, Mackenzie, and other clinicians.

Of recent work done in this country, I know of nothing more worthy of mention, or which serves better to illustrate the mutually complementary relations of experimental physiology and clinical medicine to each other than the researches of Head on the one hand, and those of Sherrington on the other, in reference to the segmentary relations of the visceral and somatic nerves of the head and body. Sherrington has succeeded in mapping out, with almost mathematical accuracy, the somatic distribution of the sensory nerves in the monkey, ingeniously surmounting the difficulties dependent on the partial overlapping of adjacent posterior root zones. But almost simultaneously, and following a totally different method, Head has encountered and largely surmounted even greater difficulties, inasmuch as the conditions presented to him have been infinitely more complex, and he has arrived at results which harmonise in a remarkable manner with those of Sherrington's more accurate and more simple experimental method. Head has founded his conclusions on the distribution of herpes, presumably conditioned by irritation of the respective posterior roots or spinal segments; and on the sympathetic or somatic expression of visceral irritation.

This principle, though first placed by the late James Ross on a more scientific basis than heretofore, is not a new one.

It was clearly enunciated by Johannes Müller,² who regarded sympathetic sensations as the result of the radiation of irritation similar to that causing reflex motor reaction; the only difference being that the radiation of impressions does not reach the motor nerves, but only affects the sensory fibres arising from the corresponding part of the cord, or, at any rate, acts on these at the same time as the motor nerves. The principle was abundantly and fruitfully applied by Laycock in the explanation of angina pectoris, and many other sympathetic neuroses connected with affections of the abdominal and pelvic viscera. But in the actual demarcation of the mutually related somatic and splanchnic segmentary zones, Head has gone far beyond previous inquirers, and has not only established facts of enormous practical value, diagnostically and therapeutically, but has largely contributed to a chapter in neurology, namely, The Sensory Innervation of the Viscera, which, in spite of the epoch-making researches of Gaskell, the valuable experiments of Langley and Anderson, and the histological work of Edgeworth, is still but very imperfectly known. For, though in harmony with Gaskell's results, it is shown by the clinical method that the spinal segments which do not give origin to splanchnic nerves—namely, the segments of the brachial and crural plexuses—are not the seat of referred visceral irritation, and that therefore the sensory nerves of the viscera have the same distribution as the visceromotor and inhibitory nerves, yet this is only a hypothesis and the segmentary relations of each viscus are at best only very obscurely indicated. By an elaborate and skilful analysis of the phenomena of referred or sympathetic pains, Head has succeeded in mapping out with marvellous detail the probable segmentary relations of each of the thoracic, abdominal, and pelvic viscera. Of still greater interest perhaps, because more obscure and more out of the range of experimental inquiry, is his determination of the zones of the head and neck which are the seat of somatic reference of irritation of the thoracic and abdominal viscera innervated by the vagoglossopharyngeal splanchnic nerve. These apparently have no relation to the peripheral distribution of the fifth nerve, but have a developmental significance, and throw much light on the constitution of the complex nucleus of the fifth nerve and its splanchnic connections. Much of this is at present perhaps only provisional or hypothetical, but there cannot be a doubt that the field of inquiry which Head has thus opened up promises to yield results of the greatest importance both in physiology and in practical medicine.

I might mention many other physiological questions the solution of which has depended on the mutual co-operation of clinical and experimental research, but my object is not so much to enumerate as to illustrate, and I think I have said enough to justify the thesis with which I set out: namely, that, though the methods of clinical and experimental research tend by the law of division of labour to diverge more and more from each other, yet even in the investigation of the vast majority of the problems of physiology, they are mutually complementary and necessary to each other, and therefore the tendency to exclusiveness should, as much as possible, be counteracted by preliminary clinical training on the part of the physiologist, and sound physiological training on the part of the clinician, along with continuous sympathetic interest in each other's labours and methods, in the full conviction that too great exclusiveness can only result in narrowness of view, and be detrimental to the best interests both of medicine and physiology.

² *Elements of Physiology*, Baly, 2nd edition, p. 750.

CHOLERA IN EGYPT.—It is reported that cholera, which has been limited to Iamietta and the district between Mensurah and Menzaleh, is abating. The Sanitary Council require that five days' notice should be given of the desire that a ship should pass through the Canal, and the passage can only be made at night if the ship is provided with the electric light. Pilots and sanitary officers to be put on board ships must undergo five days' quarantine or preventive isolation.

SUCCESSFUL VACCINATION.—Mr. Henry Caudwell, Public Vaccinator of the Nos. 1 and 2 Districts of the Woodstock Union has been awarded the grant for successful vaccination for the second time.

THE RESULTS OF SECTION OF THE TRIGEMINAL NERVE.¹

WITH REFERENCE TO THE SO-CALLED "TROPIC" INFLUENCE OF THE NERVE ON THE CORNEA.

By WILLIAM ALDREN TURNER, M.D.,

Assistant Physician, West London Hospital; and Physician to Out-Patients, Hospital for Entropy and Paralysis.

[From the Neuro-Pathological Laboratory, King's College.]

It has long been held, chiefly as a result of the experiments of Majendie and others, that progressive destructive changes occurred in the eyeball after intracranial section of the fifth nerve, and more especially of its ophthalmic branch. But the reason of this destruction has been a moot question. The corneal and conjunctival anesthesia accompanying division of the nerve or its ophthalmic branch was regarded by some as aiding the retention of irritating extraneous matter, for it was observed that, if the eye were protected from the effects of such external irritants, no inflammation followed. But this view did not receive corroboration at the hands of other observers; and disorganisation of the eye was also seen, even though there was not complete corneal anesthesia. There are on record numerous cases of anesthesia of the cornea in which no "trophic" corneal alteration was detected; nor was the view that the ocular changes differed according as the lesion was in front of or behind the Gasserian ganglion altogether acceptable; hence much divergence of opinion still exists on the subject.

The most recent experimental work bearing on this matter is that of Gaulé.² The general conclusion at which he arrived as a result of his observations upon rabbits was that the "trophic" alterations in the cornea which he described were due to lesion of the ophthalmic branch, or of the Gasserian ganglion, while they did not follow lesion of the nerve behind the ganglion. These changes consisted of numerous spots, some of which showed atrophy, others hypertrophy of the superficial corneal epithelium, hypertrophy of Descemet's membrane, necrosis and atrophy of the corneal ground substance, and the production of a fibrin-generating material in the aqueous humour. When it is also stated that these changes occurred from a few minutes to a few hours of the actual division of the nerve, it is difficult to believe that they were entirely due to the lesion thus practised.

In the series of experiments performed by Dr. Ferrier and myself the fifth nerve trunk, its ophthalmic branch, and the intramedullary roots were divided. The series consisted of four experiments involving destruction of the tubercle of Rolando, two of section of the restiform body including the "ascending" trigeminal root, four of section of the trunk of the nerve between the Gasserian ganglion and the surface of the pons Varoli, eight of the ophthalmic branch alone, and two of the "descending" or trophic root of Merkel.

Of the eighteen experiments in which anesthesia of the cornea was the prominent symptom, two only showed symptoms of destructive change and panophthalmitis. In both there was evidence of septic irritation—elevation of temperature and localised fits; and in one the *post-mortem* examination showed commencing septic meningitis. The other case is somewhat more complicated, for during the first week, in which the temperature was raised and several convulsive attacks were noticed, the cornea became distinctly opaque. From this time on till the sixth week the animal was perfectly well and the cornea clear; but at about this time the temperature again rose and panophthalmitis ensued. Another feature noticed in these two cases was the diminution of the ocular tension which occurred before there was any evidence of perforation of the corneal ulcer or prolapse of the iris.

We have also observed in many of the cases a slight corneal opacity, which showed no tendency to progress, but rather to diminish as time went on after the operation. Owing to the corneal anesthesia the lids did not approximate so closely as on the sound side; and it was in the small space corresponding to the lower pupillary margin that this opacity was detected. It was no doubt due to drying of the

corneal surface and the retention upon it of extraneous matter, which was not swept away by the movements of the lids. In the remaining fifteen cases, with the exception in some of the slight drying of the corneal surface already noticed, no opacity or ulceration was detected, although the duration of life varied from forty-eight hours to four months after the section of the nerve.

Looking more especially at the cases in which the ophthalmic branch was divided, we find that of the series of eight, one only showed destructive corneal change, and in that, as already pointed out, there was *post-mortem* evidence of septic meningitis. In one case, on the fifth day after section of the right ramus ophthalmicus, both corneae were touched with a point of lunar caustic, resulting from which a slight central corneal ulcer formed in both eyes, but no progressive change ensued, and the process of repair proceeded as well in the cornea on the side on which the ophthalmic branch had been divided as on the healthy side.

In another case, in which the nerve was divided behind the Gasserian ganglion, on the eighth day after section an irritant, probably collodion, entered the anesthetic eye. This was shortly followed by conjunctivitis, oedema of the lids, and a milky-white corneal opacity. Increasing in severity for a week, the inflammation then began to subside, and eventually disappeared at the end of a fortnight, the cornea regaining its transparency with the exception of a small central ulcer, which remained until death. In Mr. Gunn's opinion this condition was due to the shedding of the superficial corneal epithelium, and was analogous to that observed in the human eye after irritation by lime.

The two last-mentioned cases are especially instructive, for they show that whether the trunk of the nerve be divided behind the Gasserian ganglion, or whether the ophthalmic branch alone is divided, the processes of healthy nutrition and repair may go on notwithstanding the anesthetic state of the cornea.

The corneae in those cases in which the ramus ophthalmicus was divided were submitted to careful microscopical investigation. Dr. Bulloch, who made the examinations, was unable to detect any change whatsoever, either in the epithelium, the corneal corpuscles, or the ground matrix.

In two cases the "descending" trigeminal root, or trophic root of Merkel, was divided in conjunction with the superior cerebellar peduncle. In neither of these experiments was any "trophic" effect noticed upon the eye or its appendages.

The general conclusion to be drawn from a study of these experiments is that there is no evidence of trophic influence exerted by the Gasserian ganglion upon the cornea; and that, provided septic organisms are excluded, the ophthalmic branch may be safely divided or the Gasserian ganglion removed without fear of the disorganisation of the eye. The destructive changes which occur with inflammatory conditions of the basal meninges, without the existence of an external wound, would seem on this hypothesis to be due to the presence of conditions causing inflammatory irritation of the nerve.

We may look briefly at the clinical cases, in which the Gasserian ganglion has been extirpated, with special reference to the so-called trophic influence of the fifth nerve upon the cornea.

In the series of five cases reported by Rose,³ only one showed panophthalmitis and disorganisation of the eye, but there was reason to suspect that this was due to the destructive effects of the antiseptic or anesthetic used at the operation. In a second case some small, subepithelial, corneal vesicles appeared two or three weeks after the operation, but they resolved under suitable treatment.

In two others in which the cornea was protected during the operation no change was detected; while in the fifth case, in which the cornea also remained clear, there was reason to suspect that the trunk of the nerve was divided chiefly behind the ganglion. In one of these cases Dr. Ferrier found, six months after the operation, several minute pin-point depressions in the anesthetic cornea, which were not detected on the sound side. During the course of this investigation we have seen such small depressions not infrequently on the

¹ Read in the Section of Physiology at the Annual Meeting of the British Medical Association, held in London, July-August 1, 1903.

² *Compt. Rend. Acad. Sci. Paris*, 1902, p. 502.

³ *J. Soc. Ophth.*, 1902, p. 210.

anæsthetic cornea, but they appear to arise in places where the superficial corneal epithelium has been denuded.

In a case recorded by Richardson,⁴ one week after the operation a slight haziness of the cornea was observed, but as this is stated to have been present before the operation, we cannot regard it as of much significance.

In Krause's case⁵ two months after the operation the cornea remained perfectly clear, although there was complete anæsthesia both of the cornea and conjunctiva.

Doyen⁶ one year after ablation of the Gasserian ganglion found the cornea quite anæsthetic and without any evidence of trophic disturbance.

It is, therefore, seen that, with the exception of the accidental panophthalmitis in one of Rose's cases, no progressive destructive change occurred in the cornea after operation for ablation of the Gasserian ganglion. It should be borne in mind that in none of these cases has the actual position of the lesion been definitely determined by *post-mortem* examination.

It may be stated in conclusion, therefore, that the so-called neuroparalytic phenomena associated with lesion of the trigeminal nerve are evidence of irritation of the nerve, and not of paralysis. This statement holds good, whether the lesion is situated so as to implicate the ophthalmic branch, the nerve trunk, or the intramedullary root.

ON THE INFLUENCE OF THE USE OF SUGAR ON MUSCULAR WORK.*

By PROFESSOR B. T. STOKVIS, M.D., LL.D.,
Amsterdam.

The influence of sugar on muscular work is so very important, from a physiological, a dietetic, an economical, and a social point of view, that I was anxious to repeat in the Pathological Laboratory of Amsterdam the well-known experiments of Professor U. Mosso and Dr. V. Harley. I invited my pupil, Dr. Langemeyer, to examine this question in view of his inaugural dissertation, and the results he arrived at, by a long-continued and skilful examination, I now take the liberty to communicate to this Section.

Professor Angelo Mosso's ergograph is so well known that it seems quite superfluous to give a description of this ingenious instrument, by means of which the total amount of work done by the muscles of the middle finger in lifting a fixed weight till fatigue set in can be measured exactly, and the time during which the muscular work is done can be determined most easily. It is also known that if the separate experiments with the ergograph are repeated too frequently, exhaustion may follow to such an extent that the whole ergographic work is reduced to a minimum, and no further work can be done. Now, Professor U. Mosso and Dr. Pavletti found that in this period sugar taken in not too great quantities and not too concentrated was able to lessen the fatigue, so that a further rather considerable amount of muscular work could be done. On the other hand, Dr. Vaughan Harley stated that a great quantity of sugar taken in addition to the ordinary food increases the amount of muscular work in a most evident manner. The result of the publication of these researches was that the question is now often considered as decided, and that already in popular papers and journals the wages and food of workmen are treated as if the beneficial effect of the use of sugar on muscular work were a well-established scientific fact. Now Dr. Langemeyer's experiments prove that this beneficial effect does not exist, or, if it exists at all, can in no way be demonstrated by the ergograph. In his first series of experiments, which are to be considered as preliminary, ergographic work was done twice a day by Dr. Langemeyer and the assistant of the Pathological Laboratory, Dr. Lechensen, with the left and the right hand, over a period of eight weeks, in order to find out the physiological variations occurring during a regular mode of life, in respect to different hours of the day, to different individuals, to different

days, etc. We shall have afterwards to return to the results of this series of experiments.

In the second series of experiments, different kinds of sugar—sweet-tasting and not sweet-tasting sugars (cane sugar, grape sugar, milk sugar), and sweet-tasting substances not belonging to the carbo-hydrate group, for example, saccharin and dulcin—were taken before doing ergographic work, in order to ascertain if the beneficial effect of sugar should be considered as the effect of a palatable condiment and due to the excitation of the nervous system produced thereby, or as the effect of a muscular food.

The result of these experiments was, in reference to the researches of Dr. Harley, which we believed quite exact up to that time, a most unexpected one. In none of the experiments was there any evidence of a beneficial effect of the use of sugar or sweet-tasting substances on the ergographic work. I have here in view the general conclusion of this series of experiments that lasted over forty days, not the conclusion which could be drawn from one single experiment, for it happened often that the amount of ergographic work was greater after taking sugar, or milk sugar or saccharin, but as often the amount of work was diminished, and in many experiments the right hand was the only one which had gained, whereas the left had lost. Yet, the total amount of ergographic work done in this series showed a real and marked increase, in reference to the total amount of work of the first series, but as this increase was a gradual one, independent of the substances that were taken, it was most natural to consider it as a simple effect of training. And so indeed it proved, for when for a control the experiments were pursued daily during more than a fortnight, in exactly the same way, but without taking any sugar or palatable sweet condiment at all, the amount of muscular work still showed the same gradual increase, so it became obvious that the normal course of training is in no way influenced by the use of sugar.

The third series of experiments was perhaps the most interesting of all. In accordance with the experiments of Professor Ugolino Mosso and his pupils the effect of the use of sugar on almost exhausted muscles was examined in this series. It is not so easy as it seems to provoke exhaustion of the muscles engaged in ergographic work by often repeated single experiments. Even if the successive experiments done with the same hand follow each other with full speed, say after six minutes, and the weight to be lifted is a heavy one—that is, 5 to 7 kilogrammes (ordinary work is done with 3 kilogrammes)—the amount of muscular work done by trained persons still represents, after two or three hours of working, one-fourth or one-fifth of the work done in the beginning. These experiments lasted from five to six weeks, and were made by four different individuals. One of them, a tall well-grown lad of 16 years, who did not understand in the least what the experiments meant, was the only one who exhibited in the beginning of the experiments all the peculiarities of real exhaustion. After sixteen or seventeen single experiments he could not do more ergographic work. Of all, he was the most fit subject for demonstrating the beneficial effect of sugar on the exhausted muscle. Yet in his case, as in all the others, the alleged beneficial effect failed completely, at least in the first weeks, for in later weeks, training still being continued, it happened from time to time that this boy, as well as another untrained young man, after exhaustion seemed to have set in, exhibited most unexpectedly a great gain of muscular work. Once there was a gain of 3 kilogramme metres without anything being eaten, another time there was a gain of 2 kilogramme metres after the use of sugar; and, finally, an extraordinary gain of 18 kilogramme metres was found after a draught of fresh water. Without being able to decide the question whether these variations are to be considered as a mere accident or as a consequence of training, it is obvious that reliable results could not be obtained by experiments of that kind in untrained individuals. And in regard to the trained ones who took part in these experiments, I can only repeat that no effect whatsoever of the use of sugar was seen on their exhausted muscles.

In the second and third series of Dr. Langemeyer's experiments the doses of sugar were moderate ones. In his fourth and last series large doses were taken in order to examine their influence on the non-exhausted muscle, as in the experi-

ments of Dr. Vaughan Harley. As the physiological variations between different days had proved greater than the variations between morning and afternoon of the same day, Dr. Langemeyer compared the ergographic work done in the morning with that performed in the afternoon, after having taken with his luncheon at 12 o'clock 100 or 200 grammes of sugar in addition to his ordinary meal. The experiments with 200 grammes of sugar lasted seventeen days, the experiments with 100 grammes eleven days, and I lay now before you a table of the amount of work done without, and after the use of sugar.

As is easily seen, there is in these experiments no question of a marked influence of the use of sugar on muscular work. The difference between the work done in the morning and that done in the afternoon, after the use of sugar, is so very slight that it is of no value at all: and it is very remarkable that, notwithstanding the use of almost 4 kilogrammes of sugar, the amount of ergographic work as a whole in this series is even inferior to that obtained in the beginning of the experiments in the period of a strong training.

As a final experiment, the amount of daily ergographic work, taken every hour from 9.30 till 5.30, was noted, a separate tracing with each hand being taken, on days on which 250 grammes of sugar were taken in four equal portions, at 9, at 11, at 1, and at 3 o'clock, in addition to the ordinary diet, all other conditions remaining the same. On comparing the total amount of work on the sugar days with that obtained on the non-sugar days, the sugar days, give as the total time during which the weight was lifted, 1 hour and 48 minutes, with a

work of 302 kilogramme-metres; the non-sugar days, 2 hours and 8 minutes, with a work of 354.028, that is a difference of 30 minutes and 52 kilogramme metres in favour of the non-sugar days. It is interesting to note that these differences in favour of the non-sugar days are not to be considered as an average result, but that each separate day and each separate hand shows these differences in the same sense, as is easily seen in the following table:

The divergence between Dr. Langemeyer's results and those of his predecessors is as striking as possible. How is it to be explained? I venture to state that it can be fairly explained, by regarding the different factors which may influence the amount of ergographic work. In Langemeyer's researches everything was done to avoid, as completely as possible, all psychical influences by placing a low screen between the operator and the registering apparatus, so that the height to which the weight was lifted could not be seen by him. In the second place, Langemeyer succeeded, after a long time of preliminary work, in ensuring an equal method of working during the whole series of experiments. To this end, it is first necessary to fasten the arm in the instrument as tightly as possible, so that no other movement than that of the middle finger can be registered; but secondly, it is still more important that in each separate experiment there should be a perfect equality in regard to the time in which each contraction and relaxation of the finger takes place; and thirdly, in regard to the way in which the finger is moved. In regard to the time, it is obvious that the setting in movement and the relaxation of the finger, even in an interval of two seconds, can take place rapidly or rather slowly. In the first case, the interval between each single muscle contraction must be greater than in the second. Now in respect of fatigue—and all ergographic work is work till fatigue sets in—it is of course retarded by contracting the finger rapidly and letting it fall immediately after contraction, whereas moderately slow contractions and relaxations tend to induce fatigue more quickly. Therefore after the first weeks of preliminary experiments it was arranged that the contraction and the relaxation should take place, as a rule, as slowly as possible at intervals of two seconds.

It was most necessary to do so, because some persons very soon get accustomed to rapid contraction and relaxation, and thus become able to perform ergographic work six to ten times in excess to the usual work, without inducing more than the ordinary exhaustion.

Former experimenters have also drawn their attention to this point, for Professor A. Mosso spoke of it in his first communication, but is it not most remarkable that in none of the papers on the use of sugar and its influence on muscular work, this important factor is not alluded to? It is just the same with the influence of training, which, too, is never mentioned.

In regard to the third point, viz., the way in which the finger is moved, and the weight is lifted, Dr. Langemeyer found that ergographic work can be done in three ways, either by the contraction of the flexor profundus, or by the contraction of the flexor sublimis, or by contraction of the two muscles at the same time. Contraction of the flexor profundus alone produces flexion of the finger, contraction of the sublimis alone elevation, without flexion, as is easily demonstrated by mechanical pulling of the tendons of these muscles in the cadaver.

In the living subject ergographic work is usually done, and should be done, by the co-operation of these two muscles, yet a separate voluntary contraction of each of the two muscles can be easily obtained by training, in such a way that in performing ergographic work, one muscle can take the place of the other, and contraction of one is immediately followed by contraction of the other.

In this way the setting in of fatigue is again considerably retarded, and ergographic work can be performed to an amount which may many times surpass the usual work done by the simultaneous contraction of the two muscles. Ergographic work includes, therefore, many sources of error, and although I dare not say that Dr. Langemeyer's predecessors paid no heed to them, yet I am fairly persuaded that the different ways in which ergographic work can be done explain to a great extent the divergence between his results and those of former experimenters.

There is yet another point to be observed. In his preliminary experiments Dr. Langemeyer had at his disposal a great number of observations, which enabled him to be acquainted with the daily variations of the work performed under normal conditions of life. These daily variations proved, especially in the beginning of the experiments, before a real and thorough training was obtained, as great, and greater than the variations, which Dr. Harley considers as a gain caused by the use of sugar. In Dr. Harley's experiments the gain in time during which the weight was lifted, was in thirty separate tracings 519 seconds, that is, an average for one separate tracing of 17.3 seconds. Dr. Langemeyer found for himself and for Dr. Lechensen normal variations running up to 25 seconds. The gain in work was in forty separate tracings by Dr. Harley 41,938 kilogramme metres, an average of 1.3 for one separate tracing. Dr. Langemeyer found a normal variation in the beginning of his experiments of 1½ kilogramme metres and more.

To conclude, I do not hesitate to say that till now there has not been given any experimental proof of the beneficial effect of sugar on muscular work. This conclusion is not an unexpected one. Physiology teaches us that muscle is not only a most admirable living engine, in which chemical energy is transformed into mechanical work, as was so well explained last winter by my honoured friend and colleague, Professor Engelmann, of Utrecht, in his Croonian Lecture, but that it is at the same time a great storehouse of chemical substances, able to develop chemical energy. The assimilation of these chemical substances and their storage by the muscle, go on so very slowly that an immediate influence of the ingestion of food on the amount of work done by the engine is not to be expected. Manca's experiments, and the experience of daily life, teach us that even a long total abstinence from food is not able to diminish the amount of muscular power to any appreciable extent; for in muscle we have to deal with an exceedingly well provided storehouse, and with an engine working at so little expense that 80 milligrammes of sugar (glucose) are sufficient to produce an ergographic result of more than 100 kilogramme metres. In healthy persons fatigue and exhaustion, therefore, are never

caused by want of food, but solely and exclusively by want of rest; and although it cannot be contended that the chemical energy produced by the combustion of sugar is one of the chief sources of muscular work, yet there is no plausible reason why, in order to promote muscular work, sugars should be added to the daily food. All other carbo-hydrates will do as well for the provision of the muscular storehouse with the necessary stock of chemical energy.

SUGAR AS A FOOD FOR MUSCULAR TISSUE.¹

By PROFESSOR UGO LINO MOSSO, M.D.,
University of Genoa.

I AM pleased at being able to be present at the communication just made by Professor Stokvis, and take this occasion to congratulate him on the stimulus he has provoked to the study of ergographic work. There is in Professor Stokvis's work a new departure which is very interesting—namely, with regard to the different muscles which can act on the middle finger. He has thus opened a fresh chapter in the study of ergographic work. I have made many experiments with this instrument during the past twelve years, and have therefore had much practice, and I am sure that one must not rely on a few experiments alone, to oppose the experiments of others. This is not the place however to examine the *pros* and *cons* of this question; we have not even the time. But I cannot help pointing out that Dr. Stokvis has admitted that he has, when working with sugar, only obtained positive results when the subject had been trained by a series of experiments, and that he had obtained no results when the subject was at the commencement of his experiments.

This is the essential point of the whole question: a muscle not yet trained can be fatigued when there still remains a considerable amount of potential energy—then sugar has not an evident effect; but if the subject is well trained to the work, when fatigued, sugar absorbed from the alimentary tract soon becomes converted into dynamic energy, and gives to muscle the force it has just lost.

I think that Dr. Stokvis's work is not complete. In a criticism of results it is necessary not only to state that one's own experiments are in opposition to the results of others, but also to find out and show the reason, for these differences. The question of the nutrition and contraction of muscle is a most complicated one. Dr. Stokvis has said nothing as to the part the nervous system plays, and this is one of the principal factors in muscular contraction. I believe that here we may find one, if not the chief, cause of these differences.

In my first work on the influence of sugar on the work of muscle, Dr. Paoletti and myself² established that sugar and other carbo-hydrates increase the capacity for work of muscle. We have there pointed out:

1. The minimum dose of sugar which can exert an action on muscular work.
2. The limiting quantities necessary to give a certain effect.
3. The quantity of water best suited to be given with a certain weight of sugar.
4. The most convenient method of its administration.
5. The influence of age and of fatigue.

SUGAR AS A FOOD.¹

By VAUGHAN HARLEY, M.D., M.R.C.P.,

Assistant Professor of Pathology and Teacher of Chemical Pathology,
University College, London.

CARBO-HYDRATES are known to be essential to animal life, while the experiments of Wislizenus and Fick, as well as Pettenkofer and Voit, have shown that muscular work owes its origin to a great extent to a breaking up of the carbo-hydrates in the animal body and not to the nitrogenous con-

¹ Read in the Section of Physiology at the Annual Meeting of the British Medical Association, held in London, July-August, 1895.

² Prof. Ugolino Mosso e Luigi Paoletti, "Influenza dello Zucchero sul Lavoro del Muscolo," *Tras. della R. Accademia dei Lincei*. Roma, 1895.

stituents. The old experiments proving that proteids alone were essential are now considered worthless, for not only has it been found that carbo-hydrates can be formed from proteids in the organism, but the same has even been done in the test tube.

The researches of Chauveau and Kaufmann have demonstrated that sugar is the principal, if not the only, source of muscular activity, for by analysing the blood going to and coming from an active muscle and comparing it with that of a resting muscle, they found that more sugar was used up by the muscle while in action than while at rest. Their experiments led them to believe that not only did 2.5 to 3 times more blood traverse an active muscle, but 4 times more sugar disappeared from it. These observers further showed the quantity of sugar required per minute by 1 gramme of muscle at rest and when actively contracting.

Seegen, however, has shown that the results they obtained were too high, for, if they were true, the muscular tissues of a man weighing 70 kilos, would use during twenty-four hours 1,470 grammes of sugar, and if he was working eight hours of this time, no fewer than 2,884 grammes of sugar would be required. This enormous consumption of sugar would represent 6,027 calories at rest and 11,672 calories in a working man, a quantity which could not possibly be expended by our known physiological laws, so that we may see that in all probability our methods of analysis at present are not sufficiently accurate to allow us to see how much sugar per minute one group of muscles requires.

Seegen again, as well as Morat and Dufourt, showed that the amount of sugar disappearing in a muscle made to contract by electrical stimulus is greater than in a muscle at rest. Seegen also showed that in a struggling dog the venous blood contained very much less sugar than the arterial, which does not occur in the resting muscle.

Having shown the physiological reasons for believing that sugar is the primary cause of muscular activity, I shall now turn to the experiments I performed at Turin with the ergograph, by which means I was enabled to show that sugar taken as a food increased the power of doing muscular work. With this instrument the work performed by a definite group of muscles is accurately recorded; and as any one group of muscles can be taken as a standard of the effects of sugar on the muscular work of the body generally, by these means it was able to demonstrate what was the effect of the addition of sugar to ordinary diet, as well as the effect of sugar when taken alone.

In experiments of this kind it is always necessary to remember that muscles by being continuously exercised gain very considerably in power, so that it is necessary to compare the work, both with and without sugar, within a very few days when one wishes to avoid this error. Professor Stokvis draws especial attention to the necessity of being accustomed to work with the ergograph, so that in this paper I need not refer to them.

That sugar alone has a very marked effect on the muscular work performed was seen by comparing the work done during the period of twenty-four hours' fasting with that done under similar conditions when 500 grammes (17½ ounces) of sugar, dissolved in pure water, were taken. Thus I find that during 30 muscular contractions from 26 to 33 per cent. more work could be done on the day on which the 500 grammes of sugar were taken than when fasting. When instead of estimating only what amount of work could be done during a definite period—that is, 30 contractions, the total increase in two similar days was no less than 61 to 76 per cent. In fact, the work done on 500 grammes of sugar was almost equal to that done on a full ordinary diet.

That sugar should prove a diet, one would naturally expect; it was therefore advisable to investigate what effect it would have on the amount of muscular work performed, when compared to an ordinary diet. The influence of sugar, when compared to a full ordinary diet, was found to be quite appreciable. During 30 muscular contractions, during a period of twenty-four hours, 23 to 7 per cent. more work was accomplished on the day when sugar alone was taken (500 grammes or 17½ ounces) than on that when the ordinary diet was taken. The total work on these two days showed a slight increase on the sugar day (0.588 kilogramme meters) in the one case, while in the other case the full diet day was 7.430 kilo-

gramme meters more than on that when sugar alone was taken.

The influence of the addition of sugar to a full ordinary diet showed that when 250 grammes (9 ounces) of sugar were taken in addition there was a gain. During four days of comparison the gain on the sugar day during 30 muscular contractions was 6 and 13 per cent. and 11 and 20 per cent. The gain in total work was 22 and 36 per cent. and 19 and 20 per cent.

It must be remembered that during these days the individual was taking a full ordinary diet, containing all the nourishment necessary to keep him in good health, and the sugar was only added in addition to what appeared necessary for the organism. This very distinctly shows that even when the organism is supplied with, comparatively speaking, plenty of nourishment from which to obtain its muscular energy, the addition of sugar causes an appreciable increase in the muscular power.

Other experiments were done to see the influence of sugar added to a small diet when estimated only for a few hours after the meal. A small meal of coffee, milk, and rusks, with and without 200 grammes (7 ounces) of sugar, showed an increase of 9 to 21 per cent. of muscular power during thirty contractions, the total working power being increased 6 to 39 per cent.

When a large meal, consisting of soup, steak, omelette, bread, and wine was taken in one case without, in the other case with 250 grammes (9 ounces) of sugar, 30 contractions showed even then an increase of 2.3 to 8.8 per cent. of the work accomplished, while the total work increased 8.4 to 17 per cent.

The influence of sugar as a muscular diet was still further brought out by its influence on the diurnal variations which are known to occur in the power of doing muscular work. It is known by experiment that a fall in the power of doing muscular work occurs between 5 and 7 p.m., but I found that by taking 100 grammes of sugar a little before this time the diurnal fall was entirely obliterated. In fact, in some cases more work was obtained.

These experiments having proved the value of sugar as a muscular food, I shall now adduce some evidence in support of the view that sugar is a most valuable article of diet.

In the first place, Mr. W. Glynn, whose occupation was alternately laborious and sedentary, found that during a week's hard work in the open air he could take large quantities of sugar—of which he was extremely fond—without experiencing any inconvenience, whereas if he indulged in anything like the same extent during a week's desk work he suffered from feelings of drowsiness and indigestion. He further noticed that he could eat heartily of the most substantial food during sedentary occupation without experiencing these bad effects so long as he refrained from sugar. From this he concluded that, in his case at least, sugar was favourable to hard muscular exertion, and unfavourable to his constitution when he took large quantities of it without exercise. These experiments he has repeated for some years, and, although he is not a robust man, the amount of muscular work he can do on sugar surprises even his friends.

In the next place, Mr. O. A. Barber, late Superintendent of Agriculture of the Leeward Islands, in an article entitled *Sugar Cane and Health* in *Knowledge*, 1892, stated that, while 72 lbs. of sugar per head are annually used by the inhabitants of Great Britain and Ireland, by the United States 52 lbs. are used, 25 lbs. in France, and only 17 lbs. in Germany. It has been found that by adding several ounces of sugar daily to the diet of boys in schools they are rendered capable of performing an increased amount of muscular exercise.

The value of sugar is well seen in the West Indies, for when the sugar-cane crop is reaped, the negroes, however weak and starved-looking they may be, rapidly improve in condition; and although the labour in the fields is exceedingly heavy, towards the end of the harvest they are both strong and fat.

Mr. Wray states that it has been absolutely proved that a man can exist entirely on sugar. He instances a case of a crew of a ship bringing a cargo of sugar home from the tropics who by bad weather, provisions being exhausted, had recourse to their cargo of sugar; not only did it sustain

the men, but it actually cured them of scurvy, from which they had severely suffered.

Mr. Walter Pritchard states that in 1693, when among the ships discharging sugar at Leith Docks, he noticed the men ate largely of it, and they not only developed muscularly, but greatly improved in general health.

Captain H. Burke, of the 10th West Indian Regiment, the men of which are all negroes, says "that when he was with them on active service in Africa he noticed that, when making long and fatiguing marches, they valued their ration of sugar (2 ounces per diem) nearly if not quite as much as their meat ration; and that when they had no tea or cocoa in which to put their sugar they mixed it with water, and drank it thus." He further states that he frequently noticed that the men when fatigued on a long march were greatly refreshed by chewing the sugar canes that they plucked by the way. All negro races, he says, are fond of sugar, and consume immense quantities of it when they can get it. This, he thinks, perhaps accounts for their great strength and powers of sustaining prolonged and great fatigue.

The following startling, because unexpected, testimony to the bodily advantages of sugar is related at p. 286 of Douglas Sladen's *On the Cars and Off*, 1895; his exact words are: "One of the most difficult forms of nourishment to go without in the frosts of Canada as in the burning deserts of Australia seems to be sugar. Captain Armstrong told me that the only time he was ever a thief was when he had walked about twenty miles from their camp to a settler's hut to try and get provisions. His mates were all ravenous for sugar, and the settler gave him a pound which had gone bad. On his way home he apportioned himself his fair share of this sugar, because he felt that he could not wait a minute longer, and then, like a tiger which had tasted human blood, he could not resist the temptation, and, stealing of the others' shares, he ate it all and ignored the subject on his return."

Added to the above, Colonel Henry Browne, in a letter to my father, Dr. George Harley, written in the spring of last year, says that "the lumbermen of Canada, than whom no finer or more muscular men exist, eat a great deal of sugar in the form of molasses. They fill their milkless tea with it, make cakes with it, and even add it as a luxury to their fried fat salt pork, which is the only meat they get during the whole time they are in the woods cutting lumber, and this is practically half the year, their diet when at home being very much the same. The tame North American Indians, who go shooting with one, have adopted the same diet, and for toughness and endurance few can beat them. The pork is eaten for its heat-producing qualities, and I always thought the molasses might have the same effect; at any rate, I do not imagine it is taken with any reference to muscular development. A fat diet is a necessity in so cold a climate as that of Canada in the winter." That the value of sugar as a food holds good for horses is shown by the fact as stated in *St. James's Gazette*, 236, 1894, that the Emperor Azbar, of India, gave his horses 1½ lb. of sugar along with 8 lbs. of boiled peas in winter and crushed grain in summer and 2 lbs. of flour. Sir William Moore says that the natives of India when on long journeys give their horses and camels molasses refuse along with alum and opium (10 grains to a horse), and the animals thus fed are capable of sustaining a large amount of muscular fatigue.

The idea that sugar causes gout appears from experience to be totally devoid of truth. Large quantities of sugar added to the diet cause no increase of uric acid. In fact, I have found a pound or more of sugar taken daily not only causes no appreciable increase in the quantity of uric acid in the urine, but totally failed to bring on an attack of gout in a man of gouty constitution.

The popular view that sugar ruins the teeth is equally not borne out by observation, for people accustomed to taking large quantities of sugar are not more liable to bad teeth, but in many cases have exceptionally good ones. This is markedly the case with the negroes of the West Indies, who, as already stated, are accustomed to taking large quantities of sugar.

The question as to whether or not sugar causes dyspepsia is more difficult to decide. My opinion is that it is only in

They will take as much as they can get, for they value its nutritive value highly.

cases of abnormal digestive organs that an acid fermentation of sugar occurs in the stomach. If from 1 to 2 lbs. be taken daily they might cause it, but in persons who take only a few ounces per diem I have never noticed the slightest disorder of digestion to arise, although the sugar has been continued for months at a time.

I hope that by the above facts I have shown that sugar is not only an indispensable food to man, but at the same time a powerful muscular restorative, by supplying to the muscles the material from which work is produced.

Sugar is also, I believe, a nerve restorative; in my own experiments this was brought out by its effect in hindering fatigue. In the twenty-four hours of fasting, 500 grammes (17½ ounces) of sugar not only increased the amount of muscular work, but also very markedly increased the resistance to fatigue. For while during fasting a weight could only be lifted every 2 seconds from 300 to 374 seconds, when the sugar was taken it could be raised almost double the amount, being from 484 to 528 seconds. That is to say, the onset of fatigue was retarded from 154 to 184 seconds. The same influence in preventing the onset of fatigue was shown on those days in which a full diet was taken as compared to those in which sugar was added to the full diet. In the case where on two days 200 grammes of sugar was taken fatigue was hindered 12, 38, 98, and 180 seconds.

The resistance to fatigue in the case when only a small meal was taken was again negative with the left and 70 seconds with the right middle finger, while the power of resisting fatigue after a large meal was from 50 to 71 seconds. The value of sugar as a nerve restorative is well known in France and Switzerland, where when one is exhausted a glass of sugar and water is commonly given as a restorative. In what way sugar can act as a recuperative power for the nervous system is so far not to be explained, as we have no evidence that nerve cells during activity use up larger quantities of sugar than at rest, as we have in the case of the muscles. At the same time it seems a perfectly feasible supposition that this is the case, and I merely state here the facts obtained, and do not attempt to explain on any theory how they are produced.

I think that the popular experience brought forward in this paper in support of the value of sugar as a muscular food, which I gave in the *Royal Society* in November, 1893, and the full paper in the *Journal of Physiology*, vol. xvi, 1894, has been fully substantiated.

That any carbo-hydrate or even proteid will yield sugar to the organism from which muscular energy can be obtained is, I think, an undoubted fact. At the same time a certain amount of chemical energy is required to convert these substances into sugar, the form in which carbo-hydrates seem to be used as generators of muscular if not also nervous energy. The advantage of taking sugar as such in the diet is to economise energy and to save the tissues the necessity of wasting chemical energy. The mere fact that we have positive evidence of the advantage of sugar added to the diet as a food in the production of muscular work in the case of Professor Ugolino Mozzo and myself is sufficient to justify the statement that sugar should not be looked upon as a mere condiment, but as a most valuable food stuff.

Dr. M. S. PAMBRAY remarked that Dr. Harley's experiments were very unsatisfactory in that a strong personal equation entered into them. It is well known that psychical states have a most marked effect on the results when working with the ergograph. Dr. Harley approached this question with a strong view as to the effect of sugar on muscular work, and moreover he could watch the tracing as it was being taken. It is most necessary in these experiments to employ subjects who know nothing of their object.

Professor W. D. HALLIBURTON pointed out that it was well known that carbo-hydrates exerted a spring action on proteid metabolism, and that we could seek some of the explanations of the action of sugar on muscular work in this fact. He pointed out how, empirically, we had come to know that with athletes a better result was obtained by training on proteids rather than carbo-hydrates.

Professor G. N. STEWART emphasised the fact that the organism makes the best of the actual condition of things present at any time. One taking but little proteid will do good work on it, and one taking but little carbo-hydrate will

show the same. Moreover, too much may be made out of the argument based on the empirical knowledge gained in the training of athletes, for some of the hardest workers do well on less than the 100 grammes per day of proteid usually considered necessary. The work they perform is therefore largely from carbo-hydrate food.

Professor Stokvis pointed out that many of his experiments were carried out on subjects who knew nothing of their aim. He stated, too, that the Dutch crew that had performed so well at Henley and elsewhere this year had at his instigation been trained almost entirely on proteid food, but that the crew of the previous year, which had performed no less creditably, had been trained on a carbo-hydrate diet.

DEMONSTRATION OF APPARATUS.

Dr. W. H. R. RIVERS (Cambridge) showed two sets of apparatus for the determination of reaction time. The time in both cases was measured by a chronoscope, which was started by the closing of an electric current synchronous with the presentation of the sensory impression. The chronoscope was stopped by the opening of the current by the person experimented upon. By the first apparatus "choice time" was determined by the opening of one of two keys, the first to be opened when the vowel "a" the second when "o" was pronounced. The second apparatus determined "association time," and consisted of a mechanism which suddenly presented a word written on paper and at the same instant closed the circuit through the chronoscope. This circuit was opened by a lip key held closed by the person observed and opened as soon as he spoke a word called up in association with that written on the paper.

Professor Dr. BURGH BIRCH (Leeds) showed a number of instruments adapted for teaching practical physiology. The main advantages of these instruments are their solidity and efficiency combined with small cost. In all the moving parts ball bearings are used, thus minimising the friction to such an extent that all the apparatus required for eight sets of students may be driven by less than $\frac{1}{2}$ horse power. The motive power used is a "Chicago top" water motor. The maker of the instruments is Kershaw, Kankerwell Lane, Leeds. These were further illustrated by many lantern slides showing details of the arrangement of the apparatus in the class room.

ON THE PERCEPTION OF LUMINOSITY AT DIFFERENT POINTS OF THE RETINA.

Dr. F. W. EDWARDS GREEN said: It is generally supposed that vision of all kinds is most acute in the centre of the retina—that is, that we see an object best if we look straight at it. But under certain conditions this is not the case. This fact is well known to astronomers. Sir John Herschel says: "It is generally taken for granted that to see any object whatever the best way is to look straight at it, and get its image impressed on the centre of the retina. This is certainly, however, not the case with a single bright luminous point, if no brighter than a star of the third or fourth magnitude, as anybody may convince himself by trying the experiment the first clear night. When two such stars of equal magnitude, within a degree or two of each other, are looked at, nothing is easier than to make either of them disappear as if blotted out from the sky by looking full and fixedly at it, while the other remains conspicuously visible. In this way I find stars of the second magnitude considerably enfeebled, though they cannot be made wholly to disappear. Those of the first are but little affected." I have made a number of experiments in order to find out what circumstances influence this apparent disappearance of a luminous object, with the following results: A bright object cannot be influenced in any way. When a dull object is looked at fixedly (great care being taken not to move the eyes) the object will disappear from the centre, outwards, until the whole field of vision is black. The illumination must be feeble, and the source of the light must be situated behind the observer. It is of great importance to have the surroundings of the luminous point dark. I nailed a small piece of black velvet $\frac{3}{4}$ feet by 2 feet on a door

6 feet 9 inches by 2 feet 9 inches. In the centre of the velvet I put an ordinary pin at right angles to the velvet, so that only the head was visible. My left eye being bandaged, and at a distance of 11 feet, it was almost impossible to see the pin when it was looked at directly, even with a bright illumination. The pin was distinctly and brightly visible when the eye was moved so that it was seen indirectly. I then reduced the illumination, and the whole door and velvet disappeared, and the field of vision appeared as if the wall paper extended right across the door. The pattern could be made out. The disappearance commenced with an extension of the black from the velvet downwards, and then the whole door disappeared. The skirting could be seen after the other parts had disappeared. On increasing the illumination the greater part, but not the whole of the door could be made to disappear, and the disappearance was relatively evanescent; a dark object disappears when white will not. Thus a piece of white paper, an inch square, pinned on the velvet, when brightly illuminated, did not disappear with the velvet and the door, but appeared as a shining white square on the wall paper pattern which had supplanted the velvet. A feebly illuminated white could be made to disappear. When an object disappeared, the visual field appeared considerably contracted. On repeating these experiments in a room the walls of which were covered with pictures, I found that a space about 6 feet square disappeared, and was replaced by a grey cloud. The pictures on each side of the space could be plainly seen, and did not alter their positions. The luminosity of surrounding objects greatly influenced the disappearance. For instance, an isolated star in a dark sky disappeared much more quickly and rapidly than when there were several stars in close juxtaposition to the one under observation. No gap could be seen in a feebly illuminated cloud of white smoke or a number of small stars or lights. It will be noted that the experiment always succeeded best when the centre of the field of vision was occupied by a black object or a small luminous object with dark surroundings. In order to find out the points of the retina which are most sensitive to light, I substituted for the test object of the perimeter a piece of phosphorescent paper a quarter of an inch square. The above experiments show that the effect of light on the retina is not confined to the point on which it falls. This fact is also demonstrated by another experiment first mentioned by Helmholtz. Let a candle be placed in the evening in the neighbourhood of a large dark surface—for instance, of a door which opens into a dark room—and let the degree of darkness of the surface be observed while the light is alternately concealed by the finger and allowed to strike the eye. It will be readily seen that as often as the rays freely enter the eye a white luminosity appears spread on the surface, being brighter in the vicinity of the light, and spreading itself darkly over the more distant portions of the surface. The same is observed when daylight enters the eye from an orifice in a dark screen; when the orifice is covered by a coloured glass the luminosity has the colour of the latter. We know that a certain amount of light is absorbed by the pigment of the yellow spot; but this absorption cannot account for the phenomena referred to above. Besides, the yellow pigment is absent at the fovea centralis, whilst the experiment succeeds best with a small object, the image of which must wholly fall on the fovea centralis. The fact that if we look steadily at an object of two colours the whole field will become alternately of the one or the other colour bears on the same point. These experiments are hardly consistent with any other than a photo-chemical theory of colour perception, and have an important bearing on the relative functions of the rods and cones of the retina. The rods contain a substance—the visual purple—which is probably liberated by light, forming an actual photograph at the back of the retina: the cones acting as the terminal portions of the perceiving fibres, and conveying the impression of the photograph to the brain.

Professor H. P. Bowditch (Harvard) said an explanation might be found in the view that the central portions of the retina were more effective in yielding judgments of form and outline, but that intensity of light was best judged by more peripheral parts of the retina. As bearing somewhat upon

¹ Familiar Lectures on Scientific Subjects. By Sir John Herschel, Bart. 1865.

this subject he showed a card having a row of small circles coloured red on a blue background, on giving a slight rotatory movement to this card the red circles gradually disappeared and became coloured blue. Further, if one looks fixedly at one of these circles its centre gradually becomes black. He had no explanation to offer for this phenomenon.

ON THE TERTIARY DEGENERATIONS IN THE CENTRAL NERVOUS SYSTEM (SECONDARY NEURAL ATROPHY).

Dr. MARINESCO (Paris) contended that the Wallerian law of degeneration, which teaches that after section of a nerve its central end remains intact, must undergo modification. V. Monakoff, Darkewitch, and the author have brought forward facts which demonstrate the contrary. They have shown by facts derived from experiments and pathological anatomy, that when the continuity of a nerve is destroyed not only the central end undergoes a process of atrophic degeneration, but the same atrophic process overtakes the first neuron and attacks the second, and even in some cases the third. The mechanism which determines the lesions of these neurons is of a reflex nature, and the author is of opinion that the Wallerian law must therefore be altered, and that for this law must be substituted (but only with regard to the secondary neural atrophy), the trophic theory of functional afferent and efferent excitations. This theory was put forward by the author in 1892, and accepted by many other neurologists.

Professor C. S. SHERRINGTON considered the view put forward by Dr. Marinesco as an extremely valuable one, and remarked on the influence one nerve cell exerts over another, as for instance in tonus of muscles. In amputation stumps fibres of the anterior roots show signs of wasting, while there is still a potential tonus acting.

THE FUNCTION OF THE SPLEEN AS A BLOOD-DESTRUCTING ORGAN.

Dr. W. HUNTER described the results of experiments he had made on this point. He found that in the case of certain drugs possessing a markedly destructive action on the blood, action was greatly lessened, to the extent even of being completely abolished if the spleen be removed. Since in both cases the drug was injected directly into the circulation (intravenously), he concluded from the results that the cells of the spleen played an important part in the blood destruction.

THE MECHANICS OF THE CARDIAC CYCLE.

Professor J. BERRY HAYCRAFT and Dr. D. PATERSON introduced a discussion on this subject. Professor Haycraft first directed attention to the commonly accepted view of the change in shape of the ventricle during systole, namely, that the side to side diameter decreases but the antero-posterior diameter increases in magnitude. This latter result he has proved to be due to the force of gravity acting upon the heart walls in its flaccid condition during diastole. The diameters of the heart all decrease in length during systole when the heart is supported in a uniform manner from all sides, as is the case with the heart *in situ* within the thorax. Animals (dogs) killed with the heart in the extreme position of diastole, as by asphyxia, strychnine, heat, etc., were frozen, and sections cut right through the thorax in the region of the heart, and observations of its shape and diameters made. By the intravenous injection of mercuric chloride a dog was killed and the heart found firmly contracted; this, then, by a similar method yielded sections from which observations were taken. After standardising the different measurements the above conclusions could be drawn. A second point which Dr. Haycraft criticised was the generally accepted view that during systole there is a rotation of the two ventricles about a common axis resulting in a display of a greater surface of the left ventricle during systole. This observation is true when the heart is observed after removal of the sternum, but does not occur when the heart is normally supported within the thorax. The explanation of the observation is again to be found in the effect of gravity acting upon the flaccid relaxed heart, and the apparent rotation can be completely altered according to the position of the animal. If lying upon its right side, the rotation then brings into view more

of the right ventricle, and so on for different positions. Moreover, if the lungs be distended so as to yield more lateral support to the relaxed heart the usual rotation may be completely abolished. This view has further been confirmed by passing light levers through the chest wall, the inner ends being brought into contact with various parts of the heart's surface. Observations of the movements of the free end completely negative all ideas of a rotation occurring during systole. The third point raised was with regard to the time of contraction of the papillary muscle. He criticised the method employed by Professor Roy, who had formed the opinion that the papillary muscles contracted later than the remainder of the ventricular wall. Professor Haycraft had investigated this point by rapidly cutting out a papillary muscle with a piece of the ventricle wall attached, fixing this to a board so that the base of the papillary muscle was rigid, and leaving a tongue of heart wall free. This tongue was made to pull on one lever and the free end of the papillary muscle on another, and by this method, if all operations be carried out rapidly, it was shown that the two contracted quite synchronously.

Professor MICHAEL FOSTER pointed out that the systole could be divided into two parts. The first commences with the contraction, and lasts until the pressure is raised sufficiently to open the semilunar valves, and the second is from that instant to the end of the systole. During the first period there is no blood leaving the ventricle, and consequently there is no change in volume; therefore all diameters cannot be decreasing.

Professor C. S. ROY did not consider the method employed for studying the time of contraction of the papillary muscle satisfactory.

Dr. GIBSON (Edinburgh) showed tracings of the heart movements taken in a case of fissura sterni, and thought they showed an increase in the antero-posterior diameter during systole.

Dr. W. G. SPENCER did not consider the means employed to show that there was no rotation during systole at all satisfactory, and mentioned a case in which during operation to remove a cyst the great vessels were exposed. There was then seen an extraordinary amount of twisting.

Dr. D. PATERSON mentioned that the amount of mercuric chloride injected to produce a permanent contraction was very small. Further, that they had obtained rotation of the heart in either direction as they pleased by simply altering the position of the animal; and that with regard to the contraction of the papillary muscle, its action could only be properly understood on the supposition that the two contractions were synchronous.

Professor FURBER asked how one could explain the fact that the apex beat is more forcible when observed in the prone position if it were true that the flaccid heart always erects itself during systole.

INNERVATION OF THE HEART.

Professor HEYMANS (Ghent) showed a series of histological preparations, and microphotographs from these, in illustration of the innervation of the heart of vertebrates, from which he concluded: (1) The myocardium is innervated at all levels, including the apex. (2) This innervation is sufficiently copious to allow of there being one nerve fibril for each muscle fibre. (3) Each arteriole of the coronary system possesses a set of vasomotor nerves. (4) Under the endocardial endothelium there is a nerve plexus which is sensory in function: this plexus is especially rich at the level of the valves. (5) The motor fibres of the myocardium form a network among themselves in such a manner that anastomoses exist between the ramifications of neighbouring neurons.

Dr. LAUBER BRUNTON pointed out how valuable these conclusions were in enabling us to understand some symptoms and older observations. For instance, laudanum injected into the heart produced a great effect, whereas when applied externally nothing occurred. A somewhat similar result occurs, too, with strychnine.

Professor HEYMANS, in replying to some of the questions raised, stated that all his preparations had been made by Golgi's method.

LOCAL VASOMOTOR CHANGES.

Drs. BAYLISS and STARLING demonstrated a method of

studying local vasomotor changes. A tube was inserted into the course of the artery supplying the organ whose vascular changes are the subject of investigation, and two points of this tube are connected with a differential manometer. The excursions of the lever of the manometer are proportional to the velocity of blood flow through the tube, so that they are diminished by local constriction and increased by local vascular dilatation. It is necessary to defibrinate the blood of the animal (a dog was used) before the experiment, in order to avoid clotting of blood in its passage through the tube.

CIRCULATION TIME.

Professor STEWART (Cleveland, U.S.A.) communicated some further researches he had made upon circulation time. The method he had latterly been employing was to inject methylene blue into a vein, and watch for its appearance in the carotid artery. It was not found necessary to open the artery. On comparing this method with the electrical method it was found that the two gave identical results. In this way he had measured the circulation time for the spleen, heart, intestine, lung, etc. The mean pulmonary time he found to be about 9.55 seconds in a dog, and by comparison with different animals he arrived at the conclusion that the mean time for the lungs varies as a diameter of a sphere of the same mass as the animal, and having the same specific gravity. Hence the circulation time increased at a less rate for different animals than the body weight. From this the circulation time for man would probably be found to be about 15 seconds.

PHYSICAL FACTORS IN ABSORPTION.

Professor HAMBURGER (Utrecht) said: I have lately been employed with the question, as to how fluids present in the peritoneal and pericardial cavities become absorbed. Presumably, there are but two ways in which this is brought about: through the lymphatics or the blood vessels, and it turns out that the lymphatics play a quite subsidiary part. Starling and Tubby some time ago indicated this, more especially for the pleural cavity, by means of other experiments. It became now of especial interest to investigate in what way this absorption through the blood vessels was brought about. It is not by osmosis; for fluids which were both isotonic and hypertonic were equally taken up. This is such a problem as was presented to Heidenhain when he saw isotonic and hypertonic fluids, both serous or non-serous, disappear from an isolated piece of intestine with both ends occluded. As osmotic forces could not explain the facts observed, he concluded that it was a manifestation of vital force. Starling and Tubby drew the same conclusion with regard to absorption from the pleural cavity. What was more natural than that I also should conceive that the serous membrane should actively take up fluids and pass them on into the vessels lying beneath? But before I was contented with this hypothesis, I wished to know whether absorption would cease at the death of the animal. But this I found was not the case, for in animals killed some minutes, or even twenty-four or more hours previously, absorption still occurred. One might raise the objection that the serous membrane had not been killed, so I injured the peritoneum, chemically and by heat sufficiently to kill the cells, and yet both in living and dead animals absorption still went on. In my opinion then, one must no longer fall back on a vitalistic explanation; and I must mention that lately, and at about the same time as myself, Leathes and Starling have, on the basis of quite different experiments, arrived at the same result. If, now, we have to reject the explanation by "vital force," we must then seek for a fresh explanation for these facts. I believe that I have found this in imbibition. According to Ad. Fick we may distinguish two kinds of imbibition: first, molecular, that is, the sucking up of fluids by homogeneous substances, such as gelatine, agar-agar, etc.; and, secondly, capillary, i.e., imbibition into porous materials, such as porcelain, connective tissue, etc. I suggest, therefore, that when fluids are present in the peritoneal cavity, the cement substance between the endothelial cells, and possibly these cells themselves, take up the fluid by molecular imbibition. Then by capillary imbibition the fluid is taken into the connective tissue spaces, whence a small part is removed by the lymph stream. The remainder is sucked up by the

cement substance between the endothelial cells of the blood vessels, or even by the cells themselves. Now the power of imbibition by a tissue is limited. A given volume of tissue can only take up a limited volume of fluid, and in a short time the maximum swelling would be reached and absorption cease, did not the blood stream continually remove fluids taken up by the capillary walls. Hence absorption is very limited in dead animals, where the circulation has stopped, but, if one keeps up an artificial circulation of blood or serum, absorption becomes greatly increased. Clinical experience, too, teaches us that, with pathological fluids, absorption is greatly aided by an increase in the blood-flow. If, now, the possibility of absorption by dead tissue cannot be doubted, may we not explain it as possibly associated with a structure of the tissue still existing after death? Consequently, I have investigated the phenomena of absorption by artificial homogenous membranes. And I have succeeded. I have taken a cylindrical membrane of gelatine to represent the capillary, whilst the tissue spaces were imitated by a wider glass cylinder, into which the gelatine cylinder was placed. In order to form the gelatine cylinder, I took a cylinder made of nickel gauze and rotated this in warmed gelatine so that its meshes became filled. The cylinder is next removed and rotated round its long axis, and in five minutes the gelatine becomes solid. It is now placed concentrically within the glass cylinder and the open ends of this closed, leaving a free exit at either end of the gelatine tube. Both cylinders are now filled with fluid—serum, for instance—and if a stream be kept up through the gelatine cylinder, one finds that fluid is absorbed from the space between the two cylinders, and is replaced by fresh fluid which is allowed to flow in through a side tube. According to my view, it is in a similar way that fluids in the peritoneal cavity are taken up by the vessels of the subserous tissue. From what has been said we may conclude that absorption is thus a purely physical phenomenon. Later experiments have taught me that the hydrostatic pressure of the fluids to be absorbed plays a considerable part in absorption. I will not, however, here speak of these experiments, for they are not yet completed.

Dr. E. H. STARLING offered a few remarks on the paper, in which he stated that in considering the absorption of fluids from serous cavities one must not call into play any assumption of a living activity of the endothelial walls during the process. Absorption depends on the molecular structure of the surroundings, and not on the living activity of the endothelium.

ARTIFICIAL HYDREMIC PLETHORA.

Mr. J. B. LEATHES (London) described experiments showing the rate of change in volume of the fluid circulating in the vessels of an animal with artificial hydremic plethora, after ligation of the renal pedicles. The fact that normal saline was removed from the circulation much more slowly than a subnormal saline solution was explained as indicating that in the former case filtration acted alone, and in the latter was aided by osmosis, and was therefore evidence against the assumption that the vessels were stimulated by the abnormal composition of the circulating fluid to secrete the abnormal constituents as lymph, a view which would require that the solution containing more salt should be removed more rapidly. Further evidence of the ease and rapidity with which osmotic differences between blood and tissues acted was given by the fact that the volume of fluid circulating in the vessels could be increased 70 per cent. within the space of ten minutes, by the injection of 5 grammes dextrose per kilogramme of the body weight. The osmotic pressure of the lymph was found in all cases to follow very closely that of the blood; and the flow of lymph, which is very largely increased by injections of normal saline, is scarcely at all increased if the solution injected is subnormal. Both these facts were quoted as going against the secretion theory of lymph formation.

RESISTANCE OF THE CAPILLARIES TO THE BLOOD FLOW.

Dr. H. CAMPBELL read a paper in which he sought to prove that the resistance which the capillaries offer to the blood flow is very much smaller than is usually stated—so small, in fact, as to be almost negligible.

THE EXTENSIBILITY OF MUSCLE AND THE WORK PERFORMED BY MUSCLE UNDER VARYING LOADS.

Dr. T. GREGOR BRODIE mentioned some further results he had obtained upon the extensibility of muscle. Using a photographic method of recording the alterations in length he had been able to confirm his previous results, and especially that the curve of extensibility of muscle is not a hyperbola. Secondly, studying the amount of work performed during successive contractions of a muscle with uniformly increasing load and by a method previously described, he had obtained the following results. On comparing the work done when the muscle was stimulated (1) directly and (2) indirectly, the maximum amount of work, at a single contraction, was performed when the muscle was indirectly stimulated, other things being the same. This maximum occurred, too, with a lower load than in the case of the maximum performed by the muscle when stimulated directly. The amount of work performed when the muscle was stretched by the weight during the period of rest is considerably greater than when the muscle has the greater part of the weight supported during that period.

THE REGULATION OF TEMPERATURE IN ANIMALS.

Dr. M. S. PEMBERTON, who read this paper, said: The power of maintaining a constant mean temperature can be studied by observing the effect of rapid changes of external temperature upon the respiratory exchange and the temperature of an animal. In an adult mouse this power is very perfect. The mouse is able rapidly to alter its production of heat, as shown by the variation in the discharge of carbonic acid, which is a measure, although not an exact one, of the heat produced. Within ten minutes of a change from 30° to 10.5° the increase in the discharge of carbonic acid was 118 per cent.; within one minute of a change from 33.25° to 17.5° the increase was 60 per cent. The response to a rise of temperature is much less rapid; within ten minutes of a rise from 9.75° to 29° the decrease in carbonic acid was 28 per cent.; within one minute of a rise from 17° to 32° the decrease was 5 per cent. It appears that for higher temperatures a mouse regulates more by increased loss of, than by diminished production of heat. The relation between muscular activity and the production of heat is well shown; in cold surroundings the mouse is very active, whereas with a warm temperature it is quiet and often goes to sleep. The regulation by variation in the loss of heat is well marked; under the influence of a low external temperature the ears, nose, and feet become pale, whereas the effect of warmth is a flushing of these parts, and in some cases sweating occurs. The relation of muscular activity to the maintenance of a constant temperature can be studied by testing the response of an animal to changes of external temperature under conditions in which the control of the animal over its muscular system is varied. The response of the normal animal is compared with that exhibited by the animal under anaesthetics or after section of its spinal cord. Under such conditions the animal cannot regulate its production of heat, cannot maintain a constant mean temperature. The development of the power of heat regulation has also been studied. Young animals, such as the guinea-pig and chick, which are born in a high condition of development and have protective coverings, can regulate their production of heat and maintain a constant temperature. On the other hand, young animals such as mice, rats, rabbits, and pigeons, which are born blind, naked, and helpless, cannot maintain a constant temperature. As they grow the gradual development of the power of regulating the temperature of their bodies can be demonstrated.

Professor C. S. SHERRINGTON asked whether considering the variations of temperature consequent on section of the spinal cord, that this indicated the presence of a co-ordinating centre for this complicated reflex.

Dr. PEMBERTON replied that if in a mouse the cord be divided below the nerves for the shoulder girdle the animal fed itself well and lived for some few days. He did not think there was a special centre.

Professor G. N. STEWART asked if the absence of heat regulation is combined with an absence or diminution of the excitability of the skin reflexes. Further, as to how the helplessness in this respect of some newly-born animals,

such as the mouse, is made up for. Does the mother cover them more carefully?

Dr. PEMBERTON replied that he had not made any experiments in regard to the skin excitability. Mice sit constantly over their young.

NUCLEO-ALBUMINS.

Dr. W. D. HALLIBURTON maintained that the substance formerly called cell-globulin *β* by him was in reality a nucleo-proteid. This was true whether it was prepared from lymphoid structures like the thymus or the stomata of the red corpuscles. It was also true for the fibrin ferment. This fact was of considerable importance, as it placed all fibrinolytic substances prepared from the blood or tissues in the same category.

THE INTRAVASCULAR COAGULATION PRODUCED BY PROTEID-LIKE SUBSTANCES.

Dr. J. W. PICKERING said that it is well known that the intravenous injection of nucleo-proteids (nucleo-albumins) causes intravascular coagulation of the blood of dogs, rabbits, and cats. At a recent meeting of the Physiological Society and in subsequent publications I have pointed out that certain synthesised colloids discovered ten years ago by Professor Grimaux, of Paris, not only gave many of the chemical reactions hitherto deemed diagnostic of proteids, but when intravenously injected into various mammals, in 1 per cent. solutions, produced extensive intravascular clotting, which often involves the whole heart, all the larger veins, and extends along the aorta. In this communication I shall confine myself to the colloid C which is formed by the passage of a current of gaseous ammonia heated to 170° C. over solid aspartic anhydride. My attention was directed to this substance two years ago by Grimaux's assertion that after the addition of small quantities of a calcium salt it coagulated when heated to 75° C. This statement I have found to be true, and further, the substance gives a typical xanthoproteic reaction, as well as colour reactions with CuSO_4 , NiSO_4 , and $\text{CoSO}_4 + \text{KHO}$, which are strikingly similar to those given by proteids. It is also precipitated by salicyl-sulphonic acid, and the precipitate formed coagulates on heating. Neutral salts like NaCl , MgSO_4 , Na_2SO_4 , $(\text{NH}_4)_2\text{SO}_4$ separate it from solution in a manner similar to a proteid. After digestion with pepsin and 2 per cent. HCl , a substance is formed which gives a pink reaction with $\text{CuSO}_4 + \text{KHO}$ like a proteose. Extended investigations on the intravascular injection of this substance, in which I have had the advantage of collaboration with Professor Halliburton, have shown the following points of resemblance to nucleo-proteids: (1) The symptoms of death are the same—respiratory stoppage, exophthalmos, dilatation of the pupils, and stretching movements. (2) Small doses administered very slowly to dogs will retard the coagulability of the blood withdrawn from the carotid, thus giving what has been termed by writers on blood coagulation a "negative phase." (3) Carbonic dioxide favours its action. (4) Intravascular injection into albino rabbits, though followed by death, will not produce intravascular coagulation. (5) When mixed with extravascular salted plasma no coagulation is induced. (6) The inhibition of coagulability produced by the injection of potassium oxalate or of "peptone" is antagonised by intravenous injection of the colloid. The results obtained were unexpected, but it is obvious that we have a substance which in both its chemical and physiological actions behaves in a manner strikingly similar to a proteid, and may possibly be termed an elementary proteid.

MECHANICAL COAGULATION OF PROTEID.

Mr. W. RAMSDEN in this paper demonstrated that solutions of the proteids of egg-white became turbid and partly coagulated on slight agitation, the fluffy coagula formed resembling fibrin from blood in appearance and properties. This coagulation occurred equally well in a vacuum, or in an atmosphere of hydrogen, and calcium salts are unnecessary. By prolonged shaking, 96 per cent. of the total proteid of egg-white has been converted into an insoluble fibrin-like coagulum. The phenomenon is not confined to the proteids of egg white, but is

¹ Proc. Physiol. Soc., 1895, No. 2; Jour. Physiol., vol. xviii, p. 54; Comptes Rendus de l'Académie des Sciences (Paris), 17 Juin, 1895, T. xx, p. 1316.

also well marked with vitellin, myosin, a proteid obtained from potato-juice, crystalline vegetable vitellin from pumpkin seeds, and, indeed, in a more or less modified form in all proteid solutions hitherto experimented with which are coagulable by other means. The proteids of blood serum are not obviously affected by agitation unless they are first acidified, when violent shaking produces slight turbidity and a few microscopical coagula. It is only in the presence of a large quantity of neutral salt that the same fibrillated structures are met with as in egg albumen. If an alkaline solution of serum albumen be employed, half saturated with ammonium sulphate, the remarkable fact is observed that the "coagula" formed slowly dissolve up again in the very solution in which they have been formed. The less sulphate of ammonium present the more rapid the resolution. Presumably in the native serum albumen the same bodies are formed, but are instantaneously dissolved. This curious resolution suggests that the bodies formed in agitation are mere molecular aggregates, whether permanent coagula, as in egg-white, or temporary, as in alkaline serum albumen. Fibrinogen behaves like serum albumen. In some solutions of alkali albumen which did not coagulate on boiling, true coagula were formed on agitation. These very slowly dissolved up in the cold to reform alkali albumen; if warmed, much more rapidly. In the hot solution it was impossible to see that they had been formed at all. These facts are analogous to those observed in the alkaline solution of serum albumen. In some solutions of alkali albumen which had been boiled a considerable time, it was impossible to obtain mechanical coagula. Very feeble alkaline solutions of caseinogen behave like alkali albumen. If the agitation coagula are proved to be mere molecular aggregates then heat coagulation must be of the same nature. It is obviously important in making quantitative determinations of proteid not to effect saturation with salts on a "shaker."

Dr. HARRIS (Glasgow) asked whether the precipitate obtained by shaking solutions of fibrinogen was indistinguishable from fibrin.

Dr. E. H. STARLING pointed out that saturating solutions with salts for the purpose of separating globulins from albumens was, in the light of this communication, no longer admissible, as albumen would be also be precipitated. He further asked whether calcium salts were necessary.

Mr. RAMSDEN replied that it was extremely difficult to make certain that a given substance was fibrin. So far as he could judge, at any rate, some of the precipitates were not to be distinguished from fibrin. Calcium salts were unnecessary for this coagulation.

SECTION OF OTOLOGY.

Sir WILLIAM DALBY, F.R.C.S., President.

TURBINOTOMY IN CASES OF DEAFNESS AND TINNITUS AURIUM.

Mr. T. CARMALT JONES, in this paper, said that operations on the inferior turbinated bones with the object of removing or destroying the bones or the tissues covering them had been in vogue for many years. These operations had generally been done for nasal obstruction, and not with the avowed object of relieving ear trouble. He thought that in some cases of deafness turbinotomy was of use, and that in cases of tinnitus aurium relief might be hoped for after the operation. He was of opinion that the removal of hypertrophied inferior turbinata, and especially of their posterior extremities, was a thing to be tried in obstinate cases of deafness when the auditory nerve was unimpaired, and in cases of tinnitus when all the other known remedies had been tried and found wanting. A patient suffering from tinnitus and deafness came asking to be relieved of the tinnitus, saying that he would not mind the deafness if only something could be done for the noises. Much ear mischief was dependent upon some unhealthy condition of the nasopharynx. Tonsillotomy had often been done for its relief and afforded none. After Meyer called attention to adenoids it became a routine course to search for adenoids and to remove them, together with the tonsils. Often when scraping adenoids he had found the posterior nares blocked by the enlarged posterior extremities of the inferior turbinated

bones. He now had an instrument with which he removed inferior turbinata, and with which he was quite satisfied. This instrument was familiarly known as the "spokeshave," and he had operated on quite 500 turbinata. The instrument consisted of a cutting blade

turned towards the operator; an open space in front of the blade was bounded on each side by a metal arm which connected the two ends of the blade with a straight metal stem; a movable handle was fixed at right angles to the stem with a screw; the blade was bevelled slightly outwards, and was also curved outwards. The operation consisted in passing the instrument through the nostril from before backwards, the curve of the blade being outwards, pressing the blade gently outwards, drawing it slightly forward, until the posterior end of the inferior turbinal was felt to be in the open space, then one quick steady pull brought the cutting edge along between the turbinal and the outer wall of the nose. As the instrument was withdrawn the turbinal might come with it; it might be blown out afterwards; it might have to

be lifted out with forceps, it might be lost altogether, or, perhaps, only a shaving of mucous membrane was obtained. The pain varied; in some cases it was almost nil, in some it was certainly severe. The operation was frequently followed by headache. Bleeding was variable; there was always bleeding at the time; sometimes it was sufficiently copious to necessitate plugging. As to anesthetics, ether or chloroform introduced an unnecessary element of danger. A.C.E. was sufficient for children and some adults. Nitrous oxide did very well unless there was difficulty in finding the loosened turbinal. Cocaine was of use; it shrivelled up the erectile tissue, but did not anesthetise the bone; it checked the hemorrhage for a time but caused freer hemorrhage later on. In twelve cases of deafness or tinnitus, or both, where hypertrophied inferior turbinates had been spokeshaved, relief to both was noted in 8 cases, slight relief to deafness only in 1 case, no relief at all in 2 cases; 1 case of deafness with no tinnitus was improved.

Dr. MACNAUGHTON JONES deprecated the increase of turbinotomy. His opinion was that the principal cause of obstruction was in the mucous membrane and not in the osseous structures. He believed that the relation, as cause and effect, between turbinate hypertrophy and deafness was greatly exaggerated. He (Dr. Macnaughton Jones) had considerable experience in the use of the cautery for reduction of the hypertrophied mucous membrane, and had generally found it satisfactory.

Dr. BRONNER did not quite understand how the operation was intended to act. Was it to remove any obstruction? Bony obstruction was rare, and any soft obstruction could be removed by the galvano-cautery. If the operation were done to remove any local irritation at the posterior end of the lower turbinated bone, this could easily be done by the snare or cautery. The dangers of the operation were very great—primary or secondary hemorrhage, septic infection, ozena, etc. In Dr. Bronner's opinion it seemed to be a revival of the old-fashioned and abandoned method of removing the lower turbinated bones by the forceps.

Professor URRAN FRITCHARD said he would like to know the number of cases that Mr. Carmalt Jones had operated on for tinnitus, and what was the proportion of improvement to the tinnitus; also he would like to know what after-dressing was used; were antiseptic dressings used?

Dr. CHARLES WARREN quite agreed with Dr. Macnaughton Jones and Dr. Bronner that these operations were frequently performed when it was not necessary, and that milder measures effected the object desired—namely, the diminution of the hypertrophic mucous membrane, which he found in his practice was the chief condition, and which was relieved by the alkaline lotions as a wash, cocaine applications twice a day, and the galvanic cautery from time to time.

Mr. CRESSWELL BAKER asked how Mr. Carmalt Jones explained the action of the removal of the inferior turbinated bones on tinnitus; and he also wished to know whether an osseous condition had been observed after removal of the inferior turbinated body as recommended?

Dr. F. SPICER had much pleasure in endorsing all that had been said by Mr. Carmalt Jones. He said that there was no doubt that great relief might be obtained by this method in certain forms of tinnitus. As to the class of cases to be taken, this had not yet been determined; but, looking at the unsatisfactory results of ordinary treatment in very many cases, any suggestion which offered a fair prospect of success should be tried. As to the dangers of the operation, if proper care were taken and the patient prepared in the ordinary way, there was no danger, or but little. Hemorrhage sometimes occurred, and for this reason he preferred to have the patient in bed for twenty-four hours after.

Dr. PROCTOR demonstrated a series of sections under the microscope illustrating the histology of turbinate hyperplasia. They were made from specimens removed from both the middle and inferior turbinate bodies and from the wall of the septum. There were also sections through the whole length of decalcified turbinates that had been removed with the spokeshave. Most of these latter showed practically no departure from the normal condition beyond a general increase in the number of mucous racemose glands and venous sinuses and the depth of the submucous connective tissue layer. He had not found any true hypertrophy of the

visceral muscle fibre in the walls of the sinuses. These facts had nothing to do with the question of removal of the inferior turbinate body, as this operation might be strongly indicated in case of but slight enlargement, if the space occupied by the turbinate was relatively greater than the amount available in the nasal passage for the requirements of free nasal respiration. Some of the sections were from turbinate bodies as nearly normal as could be obtained, and required careful study, as the only reliable guide in investigating the departures from that condition. There were also sections through the healthy nasal mucous membrane of the ox. The next series illustrated the structure of so-called moriform hypertrophies, anterior and posterior. He pointed out the importance of distinguishing these common causes of nasal obstruction from true papillomata, with which they were still frequently confounded. They might with propriety be described as papilliform, a term aptly employed by Jonathan Wright,¹ who was one of the most recent writers on the subject. The chief histological features of these papilliform growths consisted of a projection outwards of a series of vascular loops in a bed of oedematous connective tissue enclosed by a border of ciliated epithelium. This oedematous infiltration was a characteristic of all these growths. He was inclined to think that mucoid degeneration had less to do with their production than he had hitherto believed. He had little doubt that the integrity of the walls of the venous sinuses was affected by one or the other, as Mr. Wyatt Wingrave had described, and this accounted for the attenuation of the muscular walls, as seen in some of the sections, until a mere rim was left. In earlier stages the involuntary muscle fibres were thrown into greater prominence by the surrounding oedematous infiltration of the connective tissue elements, and this he thought accounted for the apparently hypertrophic condition described by some authors. Dilatation of the vascular erectile spaces might be expected to follow the degeneration of their walls, and this condition constituted Mr. Wingrave's turbinate varix. Finally, he thought the convoluted outline of these hypertrophies was due to capillary outgrowths rather than to vasomotor influences and consequent frequent alternations of distension and contraction.

Mr. CARMALT JONES, in reply, stated that he believed that the enlarged posterior end of the turbinate acted as a foreign body and kept up Eustachian catarrh. The patients always appeared to be more comfortable after the operation, and in some cases of children where the nasal aperture was abnormally small it became gradually enlarged after the passage had been cleared.

A HITHERTO UNDESCRIBED FORM OF ROTATORY SENSATION IN LABYRINTHINE DISEASE.

Professor GUYE (Amsterdam) said that he had occasion a few months ago to show before a medical society in Amsterdam a patient suffering from Ménière's disease, who presented a peculiar form of rotatory sensation which was not quite new to him, as he had observed the same some years ago in a small number of patients, but which had not yet been described. The patient, a man aged 47, had suffered from influenza four years ago, but had not complained of his ears at the time. Since then he had enjoyed good health. He was often exposed to cold. For the last two months he had had a ringing in his left ear, and suddenly he had in July of last year an attack of giddiness, when he fell down and vomited. This attack returned at first twice daily, and later on at intervals of from ten to fourteen days. When Professor Guye showed the case he had lain in the hospital for four weeks, and had still now and then an attack, mostly without vomiting. He heard the watch at 2m. in the right ear, not at all in the left. His was a typical case of Ménière's disease. He had also symptoms of labyrinthine disease in his left ear, giddiness, rotatory sensation in the direction of the diseased ear, vomiting, and deafness. There was no symptom of any middle-ear disease. With the first attack objects appeared turning round as a wheel, or as the hands of a clock, and in the direction of the hands. When that had lasted for some time he suddenly saw everything turning away to the right; then came sickness, vomiting, and if he did not lie down soon he would fall. The rotatory sensations in Ménière's disease were, as a rule, of two forms. Mostly patients had the sensation of

¹ Trans. Amer. Laryngolog. Assoc., 1895.

rotation to the right, or to the left round a vertical axis, and, as Dr. George had shown in 1879,² to the right when the right ear, and to the left when the left ear was the diseased one. When the sensation was very sudden it might produce a reflex movement of rotation in the opposite direction. Some patients had, with the rotatory sensation to the right, the idea that the surrounding objects turned to the left. This was usually the case when the attack was severe. When the sensation was not so sudden and lasted a little longer they had the idea that the objects were turning in the same direction as their own head. It was rather remarkable that when they had slight fits, accompanied by uncertain gait in walking, they felt more propensity to fall to the side of the diseased ear than to the other side. The slight rotatory sensation in one direction produced the idea of rotation in that direction, which led to an involuntary, though not unconscious, movement in the same direction. When on the contrary the rotatory sensation was strong and sudden it produced a reflex unconscious movement in the opposite direction. This seemed to Professor Guye to be worthy of notice in the interpretation of experiences in animals where there was no other sign of the sensations than the movements induced by them. These rotatory sensations round a vertical axis might very plausibly be accounted for by irritation of the ampullæ of the horizontal canals. Besides this rotatory sensation round a vertical axis, patients generally described rotatory sensations forward and backward, as if they were turning over, and in some particular cases they described the sensation as if the objects did turn round before their face with the movement of a wheel or of the hands of a clock. If an explanation of these sensations was to be looked for in the theory of the functions of the semicircular canals, it must be remembered that the two vertical canals, which were sometimes called the frontal and the sagittal, but were better denominated as the superior and posterior canals, could, according to the theory of Cram Brown, afford rotatory sensations round two axes which are about perpendicular to each other, and to the vertical. The planes of these canals did not cut the horizontal plane in the sagittal or frontal, but in diagonal direction. The superior canal of the left ear corresponded to an axis going through the right eye and the left mastoid process. In a plane parallel to the canal lay the posterior canal of the right ear. The axis, corresponding to the superior canal of the right ear and to the posterior of the left ear, ran through the left eye and the right mastoid process. Slight rotatory sensation in these two pairs of co-ordinated canals could produce the impression that objects were turning as the hands of a clock, the dial of which must be thought of as standing before the patient, more to the right or to the left. More violent rotatory sensation originating in one of these canals would produce the sensation of falling forwards or backwards, and of turning round about an axis which did not lie transversely, but a little more to the right or to the left. Generally such patients felt so giddy that it was not easy for them to make accurate observations. But in patients who were intelligent enough to make reliable observations, especially when their attention had been directed to the questions beforehand. Dr. Guye thought it was important to make a note of their impressions, and, if possible, to compare them with the state of the internal ear as found *post mortem*. He thought this especially important on account of the theories of some French writers as Fongler and Tournier,³ who considered Ménière's disease as a neurosis occurring in mental degeneration, and the cause of which could not be found or should not be sought in the ears but in the brain, and on account of the theories of some German writers, as Böttcher and others, who looked on the static troubles produced in experiments on the semicircular canals as caused by lesions of the brain. Dr. Guye wished to draw attention to this new rotatory sensation in the first place to inquire if it had been already noticed, and, if not, to beg that it should be looked out for in future. It must not be forgotten that man alone could describe his sensations, and that in vivisections conclusions could only be drawn from reflex movements, although some English antivivisectionists had been terrified some time ago by reading that experiments on the semicircular canals had been made on deaf per-

sons. In their innocence they had translated the German *Tauben* by "deaf persons" instead of by "doves."

Professor URBAN FRITCHARD confirmed Professor Guye's observations; he agreed with him as to the semicircular canals being the seat of Ménière's disease.

Dr. T. BARR (Glasgow) stated that he had found that the descriptions given by patients of their rotatory sensations were vague and unreliable. It would be desirable to direct the patients to observe carefully the nature of the movements. In regard to the view that the semicircular canals formed the static organ of the body, that was far from being proved. In a case in which the whole of the labyrinth was removed as a sequestrum there was no disturbance of the equilibrium. Irritation, not destruction of the nerve terminus in the ampullæ and utricle, seemed to be the exciting cause by reflex action upon the centre of equilibrium in the cerebellum adjacent to the auditory centre.

Dr. A. BROWNE thought that the seat of vertigo was in the brain; the very fact that digitalis had in many instances such a beneficial effect pointed to a central origin. The varying forms of vertigo also spoke against an exclusive canal origin, as in this case the symptoms would be of a more uniform character.

Professor GUYE, in reply, said that the functions of the semicircular canal had not yet been decided. It was of the greatest importance to impress the patient with the necessity of making accurate notes of his sensations.

SOME NOTES ON A CASE OF MÉNIÈRE'S DISEASE, AND ON AN EXTREME CASE OF HYPERÆSTHESIA ACOUSTICA.

Dr. MACNAUGHTON JONES said the simple object of reciting this case of apoplexiform labyrinthine vertigo was a clinical one. To this form of vertigo he considered it best to limit the term Ménière's affection. The vertiginous seizure had many interests other than otological in its causation. The patient, aged 70, had had absolute deafness of the right ear for nine years, for which no cause could be assigned. Neither the watch nor the acoumeter were heard on contact in this ear when he consulted Dr. Jones. One month previous to this consultation, while in an omnibus, he felt a sudden flushing of the head. This was followed by a sensation of reeling and sickness. Then there was a sound "as if he were going through a railway tunnel;" and he suddenly became deaf. On examination neither watch nor acoumeter was heard in the recently affected left ear. The tuning fork was hardly heard on the head, being rather felt than heard, and any sound dying completely away on closure of the ear. He was quite unable to stand alone unsupported, falling towards the left side. On being placed with his back to Dr. Jones, and making him turn rapidly to the left, he staggered; not so on turning to the right. He was unable to write his name legibly from inability to form the letters. He was placed on iodide of potassium, bromide of strontium, and hydrobromic acid, with subcutaneous injections of pilocarpin. A month subsequently he had greatly improved; he was able to walk without a stick, the tuning fork was heard much better, the watch was heard on contact with the ear, and the acoumeter at 2½ inches. He could now write legibly and his hand was comparatively steady. The distinctive features of this case which made it typical of its kind were: (1) The suddenness of onset; (2) one ear being affected; (3) the simultaneous occurrence of the deafness, tinnitus, vertigo, and nausea, the difficulty of writing; (4) the partial recovery of hearing after the first attack and the persistence of the tinnitus. Dr. Jones mentioned as the most frequent predisposing causes of this form of vertigo—anaemia, alcoholism, gout, syphilis, rheumatism, senile arterial changes. The complications most frequently met with were albuminuria, uric acid excess, hydroemia, rigid and tortuous vessels, cardiac hypertrophy with dilatation, closure of the nasal passages from hypertrophic changes or malformations. The warning symptoms were mainly such as might be expected from these clinical and pathological conditions—that is, sense of fullness in the head, occasional buzzing in the ears, some slight deafness of a more or less periodical nature, headache, occasional transient attacks of vertigo, susceptibility to temperature and changes of atmosphere, attacks of confusion in thought and memory. The age at which the attack was most likely to occur was after 50.

² *Archives de l'Otologie*, 1879.
³ *Revue de Médecine*, 1880, 91.

The exciting causes most to be feared were mental strain in work, mental worry in business or grief, night nursing, much railway travelling, stooping occupations, the menopause, alcohol, sedentary life, bathing in cold water or sea bathing, the hot bath, especially about the catamenial periods and pregnancy. A man or woman suffering from the warning symptoms noted should moderate or abandon work for a time, take (where possible) rest and change, avoid much railway travelling, give up alcohol or only take it therapeutically, extremes of temperature in bathing should be avoided, cardiac and urinary disorders should be carefully inquired into, and dietetic errors rectified. The special predisposing cause had to be sought for and treated. Free nasal breathing should be secured. After an attack, speaking generally, the iodides, bromides (especially those of strontium and zinc), ergotin, hydrobromic acid, the vascular tonics, digitalis and straphanthus, strychnine, small doses of arsenic, and chloride of barium were the best remedies. It was one of the few groups of cases in which pilocarpin injections might be expected to do good. The particulars of an extreme case of hyperæsthesia acoustica were then given. It was hardly sufficient to explain this extraordinary sensitiveness to, and the mental effects following upon, the hearing of certain sounds, both musical notes and noises, by saying that it was due to "irritation of the auditory nerve." It seemed to him that there must be in these latter cases a condition somewhat analogous to that we are familiar with in certain cases of acute intolerance of light, both natural and artificial. The intolerance of light in cases of gouty or rheumatic retinitis, and in retinal hyperæmia, and the reflex intolerance which was present as a consequence of certain ocular conditions, might be analogous to these cases of hypersensitiveness to sound attendant upon certain middle ear disorders in reflected trigeminal irritation, and in persons whose nervous system was quite unbalanced after or during fever. But there was no condition exactly analogous in the eye to such a typical case of hyperæsthesia acoustica as the one he detailed. Here, in a woman aged 55, the hearing was, in her own language, "dreadfully acute." To hearing tests, both watch and acoumeter, she responded perfectly. Music—of which she had been particularly fond—made her "quite giddy;" she could not sit in a room with a clock, "the sound seemed so loud;" a church bell gave rise to a "babel of sounds;" she shunned a carriage in the street so great was the sense of reverberation; she could not remain in a room where her brother was speaking. Some noises sent "a shock up the spine;" most she noticed the difference in effect of certain voices. All this came on after a carriage accident and consequent blow on the head. Headache followed, and then this intolerance of certain sounds began. There had been now, at the end of seven years, a very great, though not complete, relief from the symptoms.

Professor GUYE (Amsterdam) said that in many respects he quite agreed with Dr. Macnaughton Jones, but he preferred always to try and find a local cause, which could be combated by surgical means. As regards internal drugs he had often had good results from salicylate of soda.

Dr. T. BARR (Glasgow) thought that the term *Ménière's* disease should be limited to the sudden attack produced by a sudden affection of the labyrinth. The other forms of auditory vertigo were different in their pathological nature, and were usually due to some form of pressure on the walls of the middle ear. These were very much more common than the typical form of apoplectiform deafness.

Professor URBAN PRITCHARD said he would divide auditory vertigo into two distinct forms: first, those cases in which the primary lesion was outside the internal ear, which he would call *Ménière's* symptoms; secondly, true *Ménière's* disease, in which the lesion was probably in the internal ear, of which there seemed to be two classes of cases: (a) The sudden cases in which the hearing was immediately more or less completely destroyed, with marked vertigo and rotatory movement, sickness, etc. (b) The chronic cases in which at first the hearing might not be affected, the auditory vertigo, etc., coming on in attacks, running a slow course, and ceasing when the function of the internal ear had been practically destroyed.

Dr. MACNAUGHTON JONES, in reply, said it was not sound otological practice to ignore general constitutional treatment. His case was a typical one of labyrinthine vertigo of an

apoplectiform nature, with, he believed, effusion of blood into the labyrinth. He could not attempt to go further than this in defining the locality of the effusion. His special object in bringing the case was in accordance with what had been said by Dr. Urban Pritchard and Dr. Barr to emphasise the point they referred to, that there was great looseness in the application of the term *Ménière's* disease.

ON THE ANATOMICAL CONNECTIONS OF THE MEMBRANA TYMPANI, WITH A FEW REMARKS ON THEIR PATHOLOGICAL IMPORTANCE.

Mr. RICHARD LAKE said: It must be very patent to all otologists that there is something unique in the description, as at present accepted, of the tympanic membrane when looked at from an anatomical point (briefly it is this, the drumhead is an oblique membrane closing the inner extremity of a bony canal which opens at the other externally; but it is not only this which constitutes its peculiarity: it is the fact accepted by all, that it has no connection with surrounding structures, held in position by the annulus tympanicus, and the stiffened edge of the membrane itself, almost an exact replica of a parchment drumhead proper. I must here refer to Hovell's book, where, on page 25, speaking of the membrana tympani, he goes so far ahead of his contemporaries as to say when speaking of the drum, "The former, or radiating fibres commence in the periosteum of the meatus, etc.," and I believe this to be the first if not the sole previous attempt at any description of the connections of the membrana tympani with its surrounding fibrous tissues. Such a membrane was quite suited, however, to our views of its pathology. It was from the apparent impossibility of a membrane connected only by mucous membrane and skin with the surrounding structures, being able to indulge, as it were, in an inflammation all to itself, called by a special name (*myringitis*), that the following solution presented itself to my mind, namely, either a pure *myringitis* as described did not exist, or if it did a more intimate connection of the membrana propria tympanica and other deep structures existed, and that therefore it was a secondary affection. It is, of course, quite obvious that Hovell's description is correct as far as it goes, but almost the whole of the periosteum of the meatus is continued into the membrane, probably constituting its outer fibres, and in specimen No. 2 its great tenuity is well shown; but it is a question of continuity, not of origin of fibres. This, however, is only one part of the source of its fibres: the chief source must be sought in the strong periosteum of the anterior upper wall of the bony Eustachian tube, as seen in specimen No. 1, which I send round now. In it the connection of the membrane and tube is well seen, the periosteum of the meatus being removed, also the bony wall of the Eustachian tube, and a piece of glass has been passed from the attic into the tube. The glass demonstrates at the same time a distinct semilunar fold a little above the upper extremities of the larger ossicles, apparently given off from the anterior ligament as it passes through the periosteum; superior to this curved band of periosteum there is nothing but mucoperiosteum. No. 2 shows the same, except in this specimen the periosteum of the meatus is left. Here I may remark that I have examined this microscopically, and proved that it is periosteum and not epidermis. This connection is strongest above. In No. 3, the membrane and tube are viewed from behind. In this specimen it is easy to trace the strong white glistening fibre of the periosteum, continuous on the one hand with the tubal perichondrium, and on the other into the membrana tympani. It is this part of the tube whose periosteum is shown in Nos. 1 and 2. Nos. 4 and 5 are fetal bones cut through so as to divide the Eustachian tube horizontally and the tympanum also, in 4 the annulus is left, in 5 it is removed, and I will draw your attention to the ease with which the original shape has been preserved, and in both the fact that the Eustachian tube, at this period entirely membranous, is continued directly into the membrana, the opposite side of which is connected with the periosteum of the external surface of the mastoid, and also in the fact with the periosteum lining the mastoid antrum, or, as Cheate suggested calling it, the tympanic receptacle, this connection exists in the adult, only very much reduced in importance. Having now, gentlemen,

placed before you very imperfectly my views on the anatomical connections of the membrane, I will ask your indulgence while I put before you a few considerations of more pathological importance. If these dissections are, as I think one may fairly assume them to be, typical, it seems to me that a primary inflammation of the drumhead, apart from traumatism, cannot exist. It may arise from diffuse otitis externa, but more frequently by direct extension from the Eustachian tube, as I myself have most clearly observed. Secondly, when an inflammatory exudation of the *cavum tympani* spreads outwards along the wall of the external meatus, it does so along the line of least resistance, which, as I have shown in the postero-inferior, the extension of the Eustachian periosteum preserving the anterior sections. Also I think the calcareous degeneration, when it occurs in the membrane itself, is probably due to the periosteal origin in the membrane. The presence, rare though it is, of bone corpuscles in the substance of the membrane (Politzer, Wendt, and Gruber) here receives both an explanation and a corroboration. Again, we have the presence as a normal constituent of cartilage cells, both in the edge of the membrane and external to the upper part of the malleus in the membrane. Lastly, one gets a hint as to the origin of some of these bony occlusions of the canal, as yet of uncertain origin, though I must leave this to other observers, who have more material at their command.

Dr. EDWARD LAW said that he thought Mr. Lake was mistaken in referring the first mention of the continuation of the periosteum into the tympanic membrane to Mr. Hovell's book. He believed it was stated in the translation of Politzer's *Textbook* that the embryological investigations of Draisul had demonstrated the direct continuation of the periosteum of the annulus tympanicus into the lamina propria of the tympanic membrane.

CASE OF OBJECTIVE PULSATING TINNITUS.

Mr. E. CRESSWELL BAKER read notes of this case. S. C., laundry maid, aged 19, came under treatment as an out-patient at the Brighton Throat and Ear Hospital on February 18th, 1895, with a history of deafness in the left ear and a pulsating noise in the right ear for twelve months. The noises were worse when she was fatigued. She had suffered from anaemia for about twelve months. Two years before she had also had pulsating tinnitus lasting several months, which got better under treatment. Examination of the ears showed the right tympanic membrane irregular and thinned and bulged by poltzerising. Left membrane presented an adherent cicatrix, not changed by infection. Watch heard at about 1 foot distance with either ear. Tuning fork on median line referred to left ear. On March 8th for the first time it was noticed that on inserting an auscultation tube into the right meatus a pulsating *bruit* synchronous with the pulse beat could be distinctly heard by the observer. The *bruit*, which was arrested by turning the head to the right, on rotating the head to the left was intensified until it became continuous. It was also stopped by slight pressure over the carotid artery. Examination of the chest showed no abnormal sounds over the heart and vessels. In the neck there was thought to be some fulness behind the right sternomastoid, but no tremor could be defined. *Brut de diable* on the right side of the neck. The blood was kindly examined by Dr. Adolphus J. Richardson (whose researches on anaemia are well known) and found to contain 44 per cent. of haemoglobin. The patient was ordered acid, hydrobromic, dil. π xv, tinct. ferri perchlor. π x, ter die, and under this treatment both the objective and subjective *bruits* were much diminished. She was again examined by Dr. Richardson on July 22nd, who found the haemoglobin increased to 66 per cent. At that date the hearing with the right ear was practically normal (whisper 15 feet). Rinne's test was positive on either side and the tuning-fork was well heard on both mastoids. Since this case came under my notice I have had an opportunity of seeing another case (under the care of my colleague, Mr. Treves), in which a similar *bruit* was heard on auscultating the right meatus, but in this case there was no subjective tinnitus. Cases of objective pulsating tinnitus are in my experience very rare, but such have been reported by H. N. Spencer, Wagenhauser, J. Orne Green, and Fitzgerald.

The two recorded by Dr. Orne Green¹ do not seem comparable to these cases, as there was no *bruit* in the carotids or jugulars in the neck, nor is there any mention of anaemia. Of the two recorded by Dr. O. E. Fitzgerald,² one seems similar to mine; the patient was anaemic, and the noise which was in the right ear was arrested by turning the head to the right or by pressure on the carotid. In regard to the explanation of this phenomenon, Dr. Green adopts that of Sir Benjamin Richardson for subjective tinnitus in alcoholic dyspepsia, namely, that it is "produced by a reduced vascular tension especially of the internal carotid artery, which allows the walls of the artery to be in direct contact with the osseous walls of the canal in the petrous bone, and this permits the transmission of the vibrations of the blood directly to the osseous structures in close connection with the ear." It seems to me, however, that the objective noise in my cases is more likely to be the *bruit de diable* (with exacerbations corresponding to the pulse beat) conducted to the temporal bone, and this view seems borne out by the fact of its becoming louder, as well as continuous, on rotating the head of the left and by its being arrested by slight pressure, over the carotid artery, insufficient to occlude that vessel. It is possible that by looking for them in anaemic cases we shall find these objective auditory *bruits* more common than has usually been supposed.

NOTES ON FIVE CASES OF DISEASE OF THE ATTIC, TREATED BY MODIFIED STACKE'S OPERATION.

Dr. A. BRONNER said: In many cases of chronic purulent otitis media we find it impossible by ordinary methods of treatment to cure the disease and stop the discharge. This is a sign that the attic or the mastoid antrum, or both, are affected. We can, therefore, not hope to effect a cure till these parts have been exposed and treated. The same applies to the cases of perforation of Shrapnell's membrane. These are fairly common but often overlooked, as the subjective and objective symptoms may be extremely slight. It is difficult to explain why, in some cases, the disease remains confined to the middle ear, in others it spreads into the attic, and yet in others into the mastoid antrum. The nature of the poison (scarlet fever, influenza, etc.) may partly be the cause, or the constitution of the patient (tuberculous, syphilitic, etc.); but in many cases the anatomy of the parts has a great deal to do with the extension of the disease. Hartmann³ and others have shown how the number, size, and position of the mastoid cells vary in nearly every case, and how different is the size and position of the mastoid antrum. Often we find a number of small cells near to the attic, and there is then naturally a tendency for the disease to spread to these cells, and set up permanent mischief there. If these cells are in connection with other cells, then the mastoid process will most likely also become affected. When the attic has been laid open we should carefully examine the aditus ad antrum and the neighbouring cells. If we find any carious bone, granulations, or oozing of pus, the antrum should be opened at once. Before opening up the attic from behind the ear, we should try and scrape it out from the external meatus, remove any diseased ossicles, etc. With cocaine it is not very painful. I operate according to the method suggested by Stacke, but carry the incision upwards and round the top of the ear, and pull the whole of the ear forwards and downwards. In some cases it is only necessary to cut through the upper part of the cutaneous external meatus. A bent probe—Stacke's protector is too large and clumsy—is passed into the attic and the osseous wall, *paratympanica*, separating it from the middle ear, removed with the chisel. Any mastoid cells are now carefully looked for and well scraped with the sharp spoon. If there is the slightest suspicion that the lower cells or the antrum are diseased, I remove the upper and posterior wall of the osseous external meatus, and if necessary the greater part of the mastoid process. It is of great importance that a large opening be kept in the skin, so that the operated parts can be watched for some weeks. The cases which I am briefly recording are such in which there had been disease for some years, and all ordinary methods of treatment had failed to

³ *Zeitschrift für Ohrenheilkunde*, 1894.

effect a cure, and in which the disease had spread into the attic but had not extended into the mastoid antrum: (1) Mr. W., aged 30, has had discharge from right ear as long as he can remember. There have been frequent attacks of pain. Watch was heard at 2 inches. A small polypus was seen protruding through Shrapnell's membrane. This was cauterised with chromic acid three times in May, 1893. On June 2nd the perforation had healed. In July there was again a small polypus, which disappeared after use of chromic acid. In October the pain was very severe. In November, under chloroform, an examination was made and rough bone found. The malleus and incus were diseased and removed. There was great improvement until January, 1894, when the pain became very severe and the patient consented to an operation. A large incision was made behind the ear and the cutaneous external meatus cut through. A large number of diseased cells were found near the attic. The pars epitympanica was removed with the chisel and the cells were scraped out. Wound was kept open for six months. Recovery. (2) Miss P., aged 25, has had attacks of pain in left ear for two or three years, and slight offensive discharge off and on. The attacks are becoming more frequent and more severe. Small perforation of Shrapnell's membrane was seen. In December the opening was enlarged and the diseased incus and malleus removed. In May the pain returned. In July a large incision was made behind and above the ear, the whole of the cutaneous external meatus cut through. The pars epitympanica of the attic was removed and the attic and neighbouring mastoid cells well scraped out. The upper part of wound was kept open for two and a-half months. There has been no pain or discharge since. The hearing is slightly worse. Watch can be heard at 3 inches instead of at 5 inches. (3) Mrs. S., aged 50; there has been discharge from right ear as long as she can remember. When I saw her in January, 1894, there had been attacks of severe pain in the ear for two or three months. There was a flat polypus of middle ear, which was removed by the snare and chromic acid. A bent probe could be passed into the attic, and rough bone felt there. The attic was scraped out through the external meatus four times with a small sharp spoon, and much granulation tissue removed. As the pain and discharge did not cease I opened the attic in May. There was a very large cavity, which was thoroughly scraped. In three months the wound had healed. The hearing was about the same. Watch heard on contact. (4) Mr. T. saw me in November, 1893. There has been pain of left ear for three to four months, with slight discharge. There was a small perforation of Shrapnell's membrane. In January, 1894, the cavity was gently scraped and washed out. The diseased incus came away. In June a large incision was made behind and above the ear, the pars epitympanica removed, and the enlarged attic well scraped. The fistula healed in four months. The hearing is about the same; watch just heard on contact. (5) Miss S. saw me at Eye and Ear Hospital in October, 1893. There has been discharge from the ear for eight to ten years; never much pain. A large polypus was removed; chromic acid frequently applied and iodoform drops used. There was constant recurrence of the polypus. In February, 1894, the attic was scraped out from the external meatus. In July the attic was exposed; a large number of mastoid cells were scraped out, and the posterior and upper wall of the osseous external meatus removed. In six months the fistula had healed, and there was no more discharge from the ear. The hearing had slightly improved; watch was heard at about 2 inches instead of 1. These few cases seem to show how important it is that in all cases of chronic purulent otitis media, or of perforation of Shrapnell's membrane, we should carefully examine the attic, and if necessary lay it open and remove all diseased bone. In many cases we naturally will find that the mastoid antrum is also affected, and this must then be opened. Before operating we should of course try all the ordinary methods of treatment, enlarging, if necessary, any opening of the membrana tympani, removing any polypi or granulations, and, if possible, also the malleus and incus if these are diseased or loose. These methods suffice in a large number of cases; but if they do not we should at once proceed to open up the attic thoroughly, and operate according to ordinary surgical principles. If this method of treatment were carried out hundreds of lives would be saved every year.

ON THE USE OF THE PNEUMATIC SPECULUM IN DISEASES OF THE EAR.

Dr. J. M. E. SCATTLIFF said that the comparatively meagre records of the use of a pneumatic (or aspirating) speculum in the treatment of ear diseases was sufficient apology for bringing forward the subject; more particularly as his remarks applied chiefly to the treatment by passive motion of adhesions affecting the chain of ossicles. "Siegle's speculum" was first introduced to his notice by his colleague, Mr. Cresswell Baber, some seventeen years ago, and since that time he had used it very constantly in the treatment of deafness where the tympanic membrane was entire. The uses of the instrument were various, but he wished in this paper especially to call attention to the following, namely: (1) The systematic production of passive motion of the ossicular joints and the stretching of contracted or adherent tendons of the intrinsic muscles of the tympanum. (2) The breaking down and stretching of adhesions (so common in all joints affected with rheumatoid inflammations, and which, owing to the structure of the intratympanic lining membrane, are even more likely to occur in middle-ear affections than in other regions, as I think Toynbee has indisputably demonstrated). (3) The breaking and stretching of bands of adhesions affecting the membrane itself, and, directly or indirectly, crippling the joint movements. (4) The relief of tinnitus consequent upon these morbid conditions. The diagnosis of these various maladies was in many cases very difficult, but as Dr. Urban Fritchard said, Siegle's speculum was often of great service in clearing this point up, and Toynbee—giving a list of over 1,000 *post-mortem* examinations—has proved these conditions to be of very common occurrence. Owing to the nature of the normal nasopharyngeal intratympanic air supply, these ossicles were likely to become fixed in a position causing increased rather than diminished pressure on the vestibular foramen (particularly at its anterior surface) which was just the condition most likely to be relieved by the use of the pneumatic speculum. Sometimes recovery appeared to be almost instantaneous, and such a case occurred to him in the very early days of his practice, the patient being a young officer of artillery, who was rendered deaf by a violent explosion (a long time previous to his consulting Dr. Scatliff). In his case the violent shock had probably produced some traumatic condition ending in adhesion, which so luckily yielded to suitable treatment. Other cases were accompanied by distressing tinnitus, which symptom was generally relieved for a time, and often permanently, by pneumatic treatment. In the more common class of cases, however, patience and perseverance were required, and were followed by very satisfactory results; many chronic cases recovering to a marked degree. In these cases mercurial inunction over the mastoid and drops of weak oleate of mercury iodide in the meatus have been of aid, following up the treatment by passive motion.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

A CASE OF MELENA NEONATORUM.

THE following case of this rare disease has come under my notice:—

On October 14th Mrs. B. was delivered of her sixth child, a boy. Everything proceeded normally and without the least difficulty. The infant seemed to be typically healthy, red and well nourished. After its birth it passed two natural motions and on being put to the breast took it readily. When it was 24 hours old it vomited a few ounces of blood and shortly after passed a large quantity of blood by the rectum, and died a few hours later.

I made a *post-mortem* examination and found the intestines full of blood and some blood mixed with milk in the stomach. I carefully examined these viscera, but could detect no ulceration of the mucous membrane. The other organs of the body seemed healthy, but the lungs looked rather red and were not thoroughly expanded. I sent the stomach and part of the

intestines to the Clinical Research Association for microscopic examination. Their report says: "Careful examination of the stomach and duodenum submitted to us has failed to discover any ulceration or other lesion of the intestinal wall, and the lung tissue is normal though not fully expanded."

One of Mrs. B.'s other children died of tuberculous meningitis, but the rest are healthy and there is no history of homophilia in the family.

Seaford, Sussex.

WM. FRINGEM MORGAN, M.B.

ON THE IMPORTANCE OF EXAMINING THE PERINEUM IN ALL CASES OF RAPID DELIVERY IN PRIMIPARÆ.

THE perineum is necessarily examined in all cases of instrumental delivery. But, in my own experience, it is in natural delivery, and more especially in the rapid (natural) delivery of primiparæ, that a rent in the perineum is most likely to occur. Within the last few months, I have had two typical cases of "ruptured perineum" in primiparæ from rapid delivery, no "interfering doctor" being present. In both cases the perineal rent extended close up to the anal orifice, and implicated some of the fibres of the sphincter. In the first case, having nothing with me, I borrowed an ordinary sewing needle and some white (tailor's) silk from a woman present, and although using no antiseptic, except the greatest of all antiseptics, namely, cleanliness, the wound healed perfectly by first intention within a few days. The second case I sutured with carbolic catgut ligature, and it did equally well.

In neither of these cases were there any subjective symptoms, beyond the usual soreness and tenderness consequent upon delivery, and my proposed examination was considered a work of supererogation by the nurse; however, the *mea* justified the means. The perineum should always be examined in cases of rapid delivery in primiparæ, notwithstanding that the nurse assures you that the patient is "quite comfortable."

Surgeon to the Leicester Provident Dispensary.

COMMON SALT FOR RINGWORM.

I FORWARD details of a remedy for ringworm which I have used for the past seven years. So far as I know it is entirely new. I was led to this discovery by noticing the following facts:

1. Stray dogs destroyed my favourite laurels by urinating at their roots and over the leaves.
2. My dog in the same way destroys my lawn. Urine, of course, contains a certain amount of chloride of sodium.
3. My gardener destroys weeds in the gravel paths with the same chemical element, namely, dinner salt or chloride of sodium.
4. Children who are suffering from tinea tonsurans are sent to the seaside and almost invariably improve in the salt air. This improvement has been hitherto ascribed to the general favouring influence of the open air life and improved hygienic conditions under which the children live at the seaside. But when we remember the fact that the air near the sea is impregnated with minute particles of sea water containing in solution as it does a large proportion of chloride of sodium, may we not reasonably ascribe the disappearance of the skin disease rather to this circumstance?

The considerations enumerated above arrested my attention and led me to think that common salt might prove to be a valuable remedy in ringworm. I prepared a solution and applied it in the next three cases which I was called upon to treat to the diseased scalp every night for five nights, washing it off the following morning with 10 per cent. boracic acid soap. The result of this treatment was marvellous. In less than four weeks a cure was effected in each case.

In conclusion I would remark that the penetrating character of common salt is well known and indisputable.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

HENRY TRENTHAM BUTLIN, D.C.L., F.R.C.S., President, in the Chair.

Tuesday, November 19th, 1895.

DERMOID OF THE TESTIS.

MR. JACKSON CLARKE showed a dermoid tumour of a testis which had been presented to the museum of St. Mary's Hospital by Surgeon General Giles, who removed it from an infant, aged 1 year. The following description of the specimen was given: "A right testis containing a dermoid cyst as large as a hen's egg. The cyst is everywhere surrounded by the tunica albuginea. Its cavity is almost entirely occupied by a large intracystic projection which springs from the neighbourhood of the hilum; the remaining cleft-like space within the cyst is filled with hairs and sebaceous matter. The central part of the intracystic projection contains bone and cartilage. The microscope shows the cyst to be lined with skin provided with pilo-sebaceous follicles, sweat glands, etc. No trace of the tubular structure of the testis could be found in the loose areolar tissue which separated the outer walls of the cyst from the tunica albuginea, though the vas deferens and blood vessels are normal." The condition was a rare one, only one other case being recorded in the Society's *Transactions*, namely, by D'Arcy Power. The opinions of Lannelongue, Jacobson, Bland Sutton, and others were briefly discussed. As to diagnosis, cystic sarcomata occurring in infancy were alone likely to give even a superficial resemblance to the condition in question. When the cyst occupied the interior of the testis, the treatment was that practised by Giles in this case.

CYSTIC ACCESSORY THYROID.

MR. WALTER EDMUNDS exhibited the above specimen, in which the cyst was about 1½ inch in diameter, its contents being a pale brown, glairy fluid. Into the interior of the cyst there projected two small excrescences, and attached to one part was a solid portion of tissue about the size of an almond. Microscopic examination showed the solid tissue to be thyroidal; a certain number of the vesicles contained colloid, but most of them were filled with proliferated cells. There was a certain amount of lymphoid tissue between the vesicles. The tumour was removed from near the angle of the jaw in a man, aged 23, and had been noticed three months. It lay some distance from the proper thyroid, which was not seen at the operation, and was apparently normal.

MR. JAMES BERRY observed that it was necessary to distinguish between true and spurious accessory thyroids; there were three varieties. In the first the accessory gland was quite distinct from the proper thyroid; this condition was rare. The second form was commoner. In this the accessory body was connected by means of a piece of capsule to the main gland, to the upper or lower extremities of the lateral lobes, or in the line of the lingual duct. He thought that Mr. Edmunds's case was possibly one where a pedicle had been overlooked at the time of operation. Thirdly, under the term "accessory thyroids" were sometimes included adenomata arising within the thyroid proper, and becoming secondarily pedunculated, the capsule of the main gland becoming attenuated; the whole process resembled what happened in the course of a submucous myoma of the uterus. He knew of one such case, published some years ago, where the tumour before removal projected just below and in front of the angle of the jaw; at the operation the thyroid proper was seen. Death occurred a month afterwards, when it was found that the tumour had arisen in connection with the upper part of the proper gland.

MR. J. H. TANNER referred to a calcified cystic goitre in the Museum of the Royal College of Surgeons; the pellicle lay above the division of the trachea, and presumably the proper thyroid was normal, as no contrary record was preserved.

MR. ARTHUR BARKER inquired of Mr. Berry whether any microscopic differences existed in the three varieties he had described; clinically the distinction was of little importance.

To this Mr. BERRY replied that few structural differences

were to be found; the class arising in the gland presented larger vesicles than normal thyroid tissue.

The President agreed with Mr. Berry's views; he could not hold Mr. Edmunds's case quite proven in respect to the exact source of the tumour.

CLASSIFICATION OF SARCOMATA CONNECTED WITH THE BLADDER.

Mr. J. H. TARGETT gave a lantern demonstration of tumours of the above class, showing chiefly their macroscopic characters. He criticised some of the current classifications of vesical growths in general. Clinically he adopted Mr. Hurry Fenwick's division, namely, of those occurring in children under 10 years of age and those in adults over 40, a division parallel with that devised by Mr. Butlin in regard to tumours of the testis. As to the so-called fibrous polypus, he knew of no instance. The sarcomata in children were myxosarcomata, and he was disposed to place all tumours containing mucous tissue into a single malignant category.

Mr. HURRY FENWICK remarked that polypi like those of the nasal fosse might sometimes be torn away from the bladder, whilst there existed a deeper sarcomatous tumour which produced the other formations, possibly by causing oedema. Fibroma he did not know of, and he cited one case of myxoma, probably connected with the urachus, in a Continental museum.

Mr. S. G. SHATTOCK could not see on what ground the author proposed to wipe out myxomata from vesical tumours. That myxosarcomata occurred, of course, could not be denied; but in some of Mr. Targett's cases the author had stated that there was no invasion of the muscular wall, and that no metastasis had occurred, although a large crop of growths was present. Had he discussed the existence of myxoma from the chemical side—that is, of a mucin-yielding tumour, the matter would have raised a difficult question. As to the presence of a certain number of unstriated muscle fibres present in some of the tumours, they might occur in a myxoma from the involved muscularis mucosae, in the same way that elastic fibres might be met with in myxomata, these being derived from the tissue in which the tumour had originated. The presence of closely-set cells did not disprove in itself that a tumour was not a myxoma. Virchow in his original account had described cell islands in myxoma, and the speaker had often seen close collections of connective tissue cells, not leucocytes, in common nasal polypi. Mr. Targett had also figured in one case a concomitant diffuse swelling of the mucous membrane, just like that often associated with nasal polypi and well recognised by specialists.

Mr. D'ARCY POWER referred to a specimen of sarcoma of the vagina in a child, which he had shown lately at the Society, and in which there were associated polypi of the mucous kind. He asked whether a chondro-sarcoma shown by Mr. Targett was a primary growth from the bladder.

Dr. HENRIER SNOW held that the polypoid form of vesical growths in general was due to the accident of their position.

Mr. TARGETT, in reply, regarded the chondro-sarcoma as a primary tumour; the presence of mucous tissue in vesical tumours he thought due to the degeneration of that of sarcoma.

DIFFUSE LIPOMA OF HAND AND FINGERS.

Mr. D'ARCY POWER exhibited this specimen, which might be classed as one of macrodactyly. The patient was a child, and the swelling, which was at first trivial, affected the thumb and index finger. Had operation been performed early, amputation might possibly have been avoided; the extension of fat, however, progressed steadily, and amputation became necessary, any conservative operation being impracticable. The blood vessels were not enlarged, nor was there lymphangiectasis or lymphangioma; the bones were slightly rarefied. The condition was congenital and sporadic.

MECKEL'S DIVERTICULUM.

Dr. WALSHAM showed a Meckel's diverticulum the free end of which was attached to the mesentery.

ACUTE TUBERCULOSIS OF SPLEEN REMOVED BY OPERATION.

Mr. MARRIOTT communicated this case. The spleen was successfully removed from a woman, aged 30, who had a small

ulcer on the vulva. The organ was considerably enlarged, and the seat of numerous tubercles, which histologically presented the structure of bacillary lesions. After excision the ulcer on the vulva healed; the latter was possible tuberculous, and the source of the splenic infection. No enlargement of lymphatic glands was observed clinically in any part of the body. The presence of bacilli had not been demonstrated.

PRIMARY CARCINOMA OF THE URETER.

Dr. RUNDLE recorded an example of the above condition. The growth was a squamous-celled carcinoma, which invaded the vesiculae, and by the obstruction it caused had led to hydronephrosis. The specimen came from a man, aged 46.

Mr. HURRY FENWICK stated that there existed a like specimen in the Westminster Hospital Museum.

Dr. VOLCKMER had put another on record in the Society's *Transactions*.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

EDWARD NETTLESHIP, F.R.C.S., President, in the Chair.

Thursday, November 14th, 1895.

THREE CASES OF EXOPHTHALMIC GOITRE WITH SEVERE OCULAR LESIONS.

This paper was read by Mr. JESSOP. Case I. Married woman, aged 40, had extreme proptosis of both eyes, never pregnant, menstruation always irregular, no enlarged thyroid. Operation of partial tarsorrhaphy on both eyes. Four days afterwards swelling of right conjunctiva, followed by crescentic ulcer of cornea and chemosis of left eye. Both eyes then ulcerated, and the cornea necrosed notwithstanding active treatment. The cornea were reduced to Descemet's membrane and perforated. Present condition staphyloma of both cornea and extreme swelling of the conjunctiva. The patient is still alive but very weak. Case II. A woman, aged 35, under Mr. Power. Extreme proptosis of both eyes, both cornea sloughed. The right eye was excised. Patient became insane and died. Case III. Woman, aged 24, under Mr. Vernon. Extreme proptosis; right eye sloughed, and was excised; left eye recurrent attacks of superficial corneal ulceration. Reference was made to 25 recorded cases, 7 males and 18 females. The results in the seven males were more severe, and included 4 deaths; the ages were between 38 and 56. Of the 18 females 2 died and 10 lost both eyes; the ages were between 18 and 52. The results of 3 cases of partial tarsorrhaphy in women were 2 lost both eyes and one recovered with good vision, though there was superficial corneal ulceration.

Dr. LITTLE had never seen a case bad enough to need union of the lids.

Mr. POWER had removed the eye in his case because of the continual pain and discomfort; he thought there might have been something behind the eye. He did not think the ulceration was caused by exposure, as it was not uncommon to see cases in which the eyes were never closed even during sleep, and yet no ulceration took place.

Dr. MACKENZIE DAVIDSON had had a case lately in which both cornea were destroyed; the patient became insane, but afterwards recovered. In another case he did tarsorrhaphy, and the cornea were preserved. In a third case the surface of the cornea was entirely destroyed.

Mr. LANG had performed tarsorrhaphy in one case, but the stitches yielded, and both cornea were destroyed. The stitches had had no harmful effect.

Mr. JOHNSON TAYLOR suggested that the suturing should be complete and not partial, and should be done as soon as the cornea was affected.

Mr. LAWFORD said in one case in which there was great proptosis with ulceration of cornea the lids were united at their centres instead of at the canthi; the result had been very good. He thought that union of the lids was a great safeguard.

The President had had five cases of exophthalmic goitre with damage to the cornea. His impression was in favour of lid suture, but it should be quite firm; in cases where the suture had been imperfect he had seen bad results. He preferred wire sutures. One case was in a man, aged 52, with extreme proptosis and ulceration of one cornea. After suture

the case did well. All cases were intolerant of any kind of irritation such as that produced by lotions or bandaging.

In reply, Mr. JESSOP asked that all those who had had cases should put them on record, as there were very few reported cases, and the President's observations were interesting as showing the result of one form of treatment.

THE TREATMENT OF DETACHED RETINA.

Mr. WRAY read this paper. The results of treatment in a case in which the distorted vision began in 1885 were demonstrated. The patient was seen for the first time in January, 1895. The left eye had barely perception of light, and the right eye contained a large detached retina involving about half of the fundus. The tension was decidedly raised, but the patient was and had been quite free from pain. As the other eye was quite blind from a penetrating wound, and had been so for many years, it was removed in the interest of the good eye. No more was seen of the case until January, 1895. The eye, under ophthalmoscopic examination, was found to contain a very large detachment, considerably larger than on the occasion of the last visit, so large in fact that although the media were clear, it was almost impossible to obtain a view of the disc. The tension was still markedly raised and the cornea slightly hazy. Vision reduced to hand movements 4 to 6 inches. The case was subsequently exhibited at the Ophthalmological Society. On April 7th the patient was operated on by tapping the detachment, and a quantity of dark yellowish fluid evacuated. He was then put to bed, atropine was freely used, and the eye firmly bandaged. Daily injections of pilocarpin were ordered, but had to be discontinued on the third day, on account of the patient's intolerance of the drug. A week later ophthalmoscopic examination showed there still existed a detachment of very considerable size, though the vision was improved to fingers at three or four metres. After allowing a few days for the patient to recuperate, a second operation was done, with the result that vision improved to $\frac{1}{2}$ in a good light, and the sight has fluctuated between that and $\frac{1}{2}$ ever since. The retina now appears in perfect apposition, and there exists, as is usual in such cases, a certain amount of choroido-retinal atrophy with pigmentation at the seat of the original detachment. The fields are much contracted, doubtless from the tension. The case proves that good may result from operative treatment, even in very severe cases of several years' duration. Little was to be expected from pilocarpin, and especially in elderly people and those suffering from cardiac disease. As the perfect rest treatment with atropine and bandage entailed confinement to bed for at least three to four weeks under almost insupportable conditions, and with the prospect of almost inevitable failure, it would seem better to operate at once, especially as the operation is almost free from risk under proper surgical precautions, and most surgeons do eventually operate after the failure of the simple treatment. As regards recent cases, speedy reattachment was necessary to prevent loss of function. If the subretinal fluid existed in any amount, several weeks would be required to obtain absorption and reapposition, whereas anatomical union was desirable, and probably the absence of this latter explains many relapses. In chronic cases, there will be even less tendency to rapid absorption, and therefore it would seem reasonable to tap at once, so that the period of confinement to bed is spent in promoting an actual adhesion of the retina to the choroid. Cases unsuitable for operation are those where the macula is detached, where the vitreous contains numerous bands of contractile tissue, vascular membranes, large hemorrhages, etc., and where the detachment is almost total, or the tension of the eye as low as - 3. A good result has been published in which the operation was done in a recent case with tension - 2. Claveller's experiments proved that currents of 5 milliamperes could be used for a minute without causing anything beyond transient opacity of the vitreous, and one operator published eleven cases in which he used electrolysis and obtained three ameliorations and two cures. As such currents cause only a transient opacity of the vitreous and leave no ophthalmoscopic changes behind, it is just possible that the beneficial results after electrolysis were due to leakage around the positive pole during the protracted period the needle was *in situ*. Constitutional remedies directed against gout, rheumatism, syphilis, etc., are slow in their

action, usually depressing, and after long trial have not yielded results to warrant persistence in their use as therapeutic agents for an emergency, but should undoubtedly be used later on.

Mr. DEVEREUX MARSHALL thought it unlikely that tapping the detachment where there was a growth would help the diagnosis by the examination of the fluid evacuated, as the tumour would not be broken up by tapping.

Mr. JESSOP had found, according to his experience, that after tapping the detachment returned or got worse. He had had one case in which the retina had become reattached after treatment by rest and pilocarpin; great pigmentation followed in the reattached area.

Dr. LITTLE had operated a good many times. He had had only two cases in which complete permanent cure was effected; he had seen no recoveries without operation.

Mr. SECKER WALKER advocated withdrawal of the fluid, and at the same time injection of normal saline solution into the vitreous. Temporary glaucoma ensued in one case, which passed off. The retina remained attached five weeks, but subsequently the detachment returned again.

Mr. LANG had had two cases of spontaneous cure under simple treatment by rest. He had tried puncture by various methods without success.

Mr. TWEDDY had operated by every possible method; he had never seen a permanent cure; he had seen improvement. He questioned the diagnosis in cases of cure. He thought it right to do scleral puncture, however. The most successful case was that of a nurse who was myopic; the vision was reduced to hand movements. After rest and pilocarpin treatment vision was restored to J.I. The improvement lasted some time.

The President was able to give the further history of this case. He had seen the patient seventeen months later; she was quite well, and there was no sign of detachment.

Mr. POWER had seen the suggestion made that an injection of fresh vitreous of a cat or dog should be made into the vitreous to reapply the retina by pressure.

Mr. JOHNSON TAYLOR asked if elaterium had been used as treatment by any of the members.

Mr. GRIMSDALE had seen Mr. Frost attempt to inject vitreous, but he had found it impossible to make the vitreous flow through a syringe.

HARVEIAN SOCIETY OF LONDON.

Sir JOHN WILLIAMS, Bart., M.D., F.R.C.P., President, in the Chair.

Thursday, November 7th, 1895.

SPASMODIC ASTHMA.

Dr. GOODHART read a paper on spasmodic asthma, which he regarded as a purely nervous phenomenon, giving reasons for this view. He dwelt also on the fact that it began most commonly in early life, and was then most tractable. In connection with treatment he considered the usual palliatives, and especially the patent and other fumes, as worse than useless. The attack itself might be relieved by injections of morphia or the administration of chloroform, and when impending was often met by a combination of potassium iodide with lobelia. A rational treatment, however, must deal with the morbid propensity, and various measures would suggest themselves under different circumstances. Generally speaking, exposure to bracing air, healthy exercise, and an ordinary careful diet was to be preferred to the system of coddling sometimes adopted.

Dr. ILLINGWORTH showed the analogy which existed not only between asthma and epilepsy, but also between that and migraine, angina, and flatulent colic; the symptoms in all being fundamentally similar—collapse, with feeble pulse, low temperature, and pain of a heavy, dull, leaden character. He grouped these together in a hitherto undescribed set of venous disorders, and named them the "anginal group." The accepted pathology he regarded as entirely erroneous. The symptoms pointed to venous congestion with consequent effusion of carbonic acid gas into the air cells. Hence the short inspiratory efforts and prolonged expiratory ones, and the relief felt by putting the head low down to allow this heavy gas to flow out. All these disorders were benefited by

nitrites, but especially by belladonna in large and frequent doses. The relief got from potassium iodide was from its fluidising effect upon the stagnating blood. Antifebrin acted well in the same way. Hay asthma he averred to be rapidly curable by inhalations and douches of solution of biniodide of mercury (1 in 1,000).

Mr. PARKER YOUNG came to the meeting to learn if there was any fresh remedy or treatment, as he, like many other members, suffered from the complaint. Out of the remedies suggested he had found fumes of saltpetre dissolved in blotting paper and the inhalation of chloroform the most efficacious. His attacks came on from hurrying and in going up a hill; the attacks of dyspnoea were very severe; formerly he also found that addressing public meetings, and excitement, etc., affected the nervous system; the pneumogastric nerve playing an important part, relief coming from vomiting, sleep, or exciting the mucous membrane of the nasal organs to copious secretion. He thought there was yet much to learn in the disease, and his experience of drugs as suggested by various speakers was not as satisfactory as he could wish. They had been tried by his friend, Dr. Lyle, sitting on his right, with not very beneficial results, although a fellow sufferer.

Dr. EDWARD SQUIRE was disposed to question whether asthma was more particularly a disease of the upper strata of society. As to age, he asked whether the preponderance of children might not partly be explained by the fact that asthmatic children were brought to the doctor in the hope that the disease might be cured before they grew up, whilst the adult asthmatic, despairing of cure, and having found some remedy which eased his attack, treated himself with his favourite "fume" or powder. Dr. Squire unhesitatingly expressed his preference for the "fresh air" over the "hot house" treatment. Undue "coddling" was, in his opinion, harmful. With regard to localities suitable for asthmatics, nothing could be said in general terms; each patient must find out for himself what locality suited him best. Some asthmatics were better in the open country, some in the smoky atmosphere of a manufacturing town. As to drugs, Dr. Squire had had such satisfactory results from iodide of potassium in large doses (grs. x to xx, three times a day), that he generally prescribed this for adults. He had often seen patients, who had had frequent attacks before admission, keep free from attacks for the six weeks or more whilst in hospital. The iodide could not, however, be considered a cure for the disease, as the attacks generally returned when the remedy was discontinued. Chloroform inhalation was sometimes useful during an attack, but required to be used with care. He had seen alarming collapse follow chloroform inhalation during an asthmatic attack. Morphine hypodermically would always give relief. The various "fumes" were undoubtedly useful in many cases. He advocated examination of the nose in asthmatic patients; he had had cases in children where removal of adenoids had cured asthma. He considered the prognosis good in children, but the disease was much more intractable in adults.

Dr. GREVILLE MACDONALD said that of 30 cases of asthma associated with nose disease he had had 20 manifestly relieved by local treatment, while of these 12 might be quoted as tantamount to complete cures. Of the 20, 4 were cases of obstruction due to septal deformities, 6 were vascular tumefaction or hypertrophy of the inferior turbinated bodies, 4 were polypus, and 4 adenoids; while the remaining 2 were instances of that curious oedematous swelling over the upper and anterior portion of the triangular cartilage so often associated with paroxysmal sneezing. The remaining 10 were all sufferers from polypus. He believed that the latter was more often associated with chronic bronchitis than simple spasmodic asthma, and must be considered as a concomitant rather than as responsible for the bronchial symptoms. From these statistics he purposely excluded cases of hay asthma; for he regretted to confess that he had but seldom found this symptom relieved by intranasal operation, although so far as the more severe symptom, the sneezing, was concerned, he was greatly encouraged at the results of treatment. He gave particulars of 3 cases of complete cure of severe spasmodic asthma which had been treated by himself, the result of operation being so immediate and so emphatic that there could be no doubt that the *post hoc* was *propter hoc*. He

believed that spasmodic asthma together with paroxysmal sneezing were more frequently seen in the out-patient departments than ten years ago, and that the two could no longer be considered as among the privileges of the upper classes.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

PATHOLOGICAL AND CLINICAL SECTION.

WILLIAM THOMAS, M.B., F.R.C.S., in the Chair.

Friday, October 25th, 1895.

PUNCTURED WOUND OF HEART.

Mr. A. LUCAS showed a youth who had recovered from a stab near the left nipple, attended by severe symptoms. From the profuse hemorrhage, profound shock, hæmorrhax, and pericarditis Mr. Lucas inferred there had been a puncture of the wall of the right ventricle, and he had verified by experiments on the cadaver that in stabs similar to the one described the right ventricle was wounded.

CONGENITAL DISLOCATION OF BOTH KNEES FORWARDS.

Mr. L. GAMGEE showed a child, aged 3½ months, with congenital dislocation of both tibiae forwards and rather outwards. Both knees were in a position of marked hyperextension, and could not be flexed. The patellæ appeared to be absent.

MORBID ANATOMY OF THE ENLARGED CIRRHOTIC LIVER.

Dr. FOXWELL showed microscopic sections taken from large (92 ozs.) and small (46 ozs.) alcoholic livers, exhibiting (a) fibrous tissue penetrating to the centre of the lobules—that is, intralobular cirrhosis—in both livers; (b) a larger amount of fatty change in the small than in the large liver. These appearances were in accordance with Dr. Foxwell's belief that there is no special character in the anatomical distribution of fibrous tissue in the cirrhosis arising from alcohol, and that when the alcoholic liver is enlarged the enlargement is not usually due to fat. Another section exhibited the deposit of fibrous tissue around the hepatic vein in a case of cardiac disease. The occurrence of this central cardiac cirrhosis Dr. Foxwell did not think was sufficiently insisted upon, though he thought it arose oftener than the peripheral (portal) cirrhosis, which authors frequently described as the result of cardiac feebleness.

SPLENIC ANEMIA.

Dr. DOUGLAS STANLEY showed the organs from two cases of "splenic anemia." Both cases were males, and had been under observation for a considerable period. In one there had been very marked anemia for several years, characterised by great reduction in the number of red blood corpuscles, with marked scarcity of the white. There was great enlargement of the spleen, and latterly some pigmentation of the skin. Death was due to acute peritonitis, caused by perforation of a gastric ulcer. The spleen (2 lbs. 8 ozs.) was extremely firm and the capsule much thickened. On section it showed considerable fibrosis. There was nothing resembling the lesions of Hodgkin's disease. The pancreas was indurated; the liver showed some cirrhosis of recent date; the bone marrow was very red and gelatinous. The second case showed the same conditions during life, but death was due to severe hæmatemesis. Similar changes were found *post mortem*, but the suprarenals were extremely atrophic. In the first case they were not reduced in size, but were somewhat firm, and showed marked fatty degeneration.

UNITED INTESTINE WITH MURPHY'S BUTTON IN SITU.

Mr. BARLING showed a specimen of small intestine with a Murphy button *in situ*. The specimen was taken from a case of strangulated femoral hernia (a female, aged 34) in which the gut had perforated on the fourth, or perhaps the third, day after herniotomy. Strangulation had existed for about sixty hours, and on opening the sac a small loop of claret-coloured oedematous gut was found, which, when the constriction was divided, slipped back before any examination could be made of the lines of constriction on the gut. All went well until three days after, when the patient complained of discomfort in the abdomen, but there was no tenderness, distension, or vomiting. On the fourth day there was com-

plaint of severe abdominal pain, the abdomen was distended, tender, and very resonant in the umbilical region. The pulse had increased from about 80 to 116, and the respiration from 20 to 32. The bowels had not acted since the operation. The abdomen was opened in the middle line, and a quantity of free gas let out. Semi-purulent fluid and intestinal contents were found in the lower part of the abdomen, and there appeared to be general peritonitis. The intestines were adherent around the perforation, which lay some inches above the femoral ring, and from which leakage was still going on. About three inches of small intestine was resected, the ends were united by a three-quarter-inch button, and the belly was thoroughly flushed and drained. The patient died thirty-six hours later of an advancing peritonitis. The necropsy showed that union was going on satisfactorily, but that at one point, where the lower margin of the button impinged on the intestinal wall, the pressure had produced destruction, and only the peritoneum still remained unperforated. It was possible that the presence of peritonitis was a contra-indication to the use of the button, as when it existed, the sodden and oedematous intestinal walls were more likely to suffer from pressure by the weight of the button than the walls of healthy intestine.

SPECIMEN.

Dr. KAUFFMANN showed a specimen of a "Benign Epithelial Tumour" of the soft palate.

MANCHESTER MEDICAL SOCIETY.

F. A. SOUTHAM, M.B., F.R.C.S., President, in the Chair.

Wednesday, November 6th, 1895.

CERVICAL PACHYMENINGITIS.

Dr. LEECH showed a patient who first came under his care nineteen years ago, being then 15. He was suffering from loss of power over both arms and the left leg. Prior to the paralysis he had had an abscess at the back of his neck, and through a sinus which resulted a piece of bone of considerable size had been discharged. Soon after admission to the infirmary power was entirely lost in the arms and legs, the muscles were rigid, the deep reflexes much exaggerated, and tremors were easily produced. The muscles of the upper extremity were wasted, and there was characteristic deformity of the hands. He had incontinence of urine and some anaesthesia. The body remained completely paralysed for many months, yet eventually he recovered. He could not stand for two years, and three years elapsed before he could walk. For sixteen years he has remained well and able to work. The right hand is a little deformed, and the reflexes are unduly marked, otherwise he is in good health.

PULSATING ORBITAL SWELLING.

Mr. THOMAS JONES showed a case in which both common carotid arteries had been tied for a pulsating swelling in the right orbit. The patient, a woman, aged 21, was confined in January, 1891, after a tedious labour of thirty-six hours. Immediately after the birth of the child the patient noticed a peculiar noise in the head, which she compared to a loud knocking at the door. This sensation was most noticeable on the right side of the head, and it was not attended with any pain. Fourteen days later both eyes became swollen, but the condition did not persist in the left eye. A little later the right eye began to protrude, and after two months the protrusion was most noticeable. She was for a few weeks under treatment, which consisted of rest in bed and intermittent pressure on the right carotid artery. No benefit being derived, she was admitted into the infirmary in December, 1891. Symptoms usually associated with orbital aneurysm were present in a more or less marked degree. Ligation of the right common carotid artery was performed in August, 1892, after a further trial of digital compression of the artery had been made. The patient made a good recovery, and there was a marked improvement in her condition for a time, until a violent attack of coughing which was attended with much straining. Pulsation and the other symptoms returned in the orbital swelling. Her condition remained stationary for many months; then she received an accidental blow from a child's elbow, and an aggravation of the symptoms followed. She was readmitted last January, and, as it was found that the pulsation in the swelling could

be controlled by pressure on the left common carotid artery, this vessel was secured. The benefit was of a very temporary character. Her condition now is very much what it was when she first came under observation, and the question was discussed whether injections of coagulants into the dilated pulsating veins would not be a justifiable proceeding. If the patient gives her consent she will be again admitted for further treatment.

ABSCESS OF SPLEEN.

Mr. JOSEPH COLLIER mentioned the case of a woman, aged 45, married, no history of injury, had never lived abroad, was admitted to Crumpsall Hospital with signs of left pleurisy. Later high temperature, much pain in left side, afterwards bulging in left hypochondrium, which increased; was fluctuant, and slightly pulsating. Abscess of spleen was diagnosed, with hæmorrhage from splenic substance into its cavity. Patient in very low condition. Had abscess opened, and over a pint of blood-stained pus, blood clot, and broken-down splenic substance was removed. Hæmorrhage from the remaining portion of spleen easily controlled by pressure with sponge towards hilum. Remains of spleen scraped out with lithotomy scoop, and cavity packed with iodoform gauze. No further bleeding occurred, but patient died collapsed in twenty-five hours. *Post mortem* examination showed no peritonitis, but peritoneum pushed down by abscess; there had been no hæmorrhage into the large abscess cavity. There was also left basal pneumonia. No other abscess found. No endocarditis. No evidence of pyæmia, tubercle, syphilis, or pyelo-phlebitis. Abscess was apparently idiopathic.

IPECACUANHA ALKALOIDS.

Dr. R. B. WILD read a paper on the pharmacology of the ipecacuanha alkaloids, in which was detailed the results of a number of experiments upon emetine and cephaeline, the two alkaloids recently described by Paul and Gownley.

LIVERPOOL MEDICAL INSTITUTION.

CHAUNCY PUZEY, F.R.C.S., President, in the Chair.

Thursday, November 14th, 1895.

SUCCESSFUL CASE OF CHOLECYSTOTOMY.

Mr. CLEGG showed a young woman, aged 26, from whose gall bladder he had removed several calculi.

Drs. RAWDON and O'HAGAN made remarks.

IS CANCER CURABLE BY SURGICAL OPERATION?

Dr. DAVIES, in opening a discussion on this subject, said that evidence went to prove that cancer was something far other than a mere local disease. In 53 cases of uterine cancer submitted to the operation of complete hysterectomy, there was early recurrence in almost every instance. Numerous authorities advocated and described partial or complete hysterectomy, but their writings did not contain the facts as to the actual benefit derived from the operation. In his opinion patients with recurrence of the disease suffered more acutely than those in whom it had never been touched. Cancer of the alimentary tract was as unsatisfactory as the uterine form, and more reliable details of results were much needed. He held that the subsequent and remote results of operation on breast cancer were very bad, notwithstanding that the operation was becoming more and more radical, with "clean sweeping" of the axilla and even removal of the arm; statistics immediate and remote would be a great help. There was no evidence that cases of non-recurrence were also examples of early operation. Patients ordinarily lived for two or three years whether treated by surgery or left alone. When cases lived for ten or even twenty years after operation, the question to determine was whether they were ever cancer at all. Dr. Davies, in concluding, advocated the serial and methodic investigation of a large number of cases extending over many years, such inquiry to be duly audited by a competent committee.

Mr. PAUL thought that in practice there was no such diversity of opinion amongst the surgical leaders as Dr. Davies had suggested. Having given the facts upon which his views were based, he expressed the opinion that cancer was local in origin, but could only occur in tissues favourably predisposed to its growth, and that it could be cured in the same sense that a tuberculous joint could be cured, by ex-

dision. He gave his results in the surgical treatment of cancer of the alimentary tract. The best successes quoted were in cancer of the lip, gum, cheek, rectum, and anus, but he believed the pylorus and colon would yield equally good results in time. Finally, he considered that surgical success depended upon early recognition, thorough extirpation, inherent favourable tendencies in the tumour, and judicious constitutional after treatment.

Mr. BANKS dwelt more particularly on cancer of the breast. He believed in a cancerous diathesis, but that some local irritation was necessary to start the disease. If the portion of the economy so affected could be clean scooped-out "like the bad bit out of an apple," there was no absolute reason why the disease should not be eradicated. If once you admitted that cancer was a purely diathetical disease, you might give up all attempts at its removal, for whatever you did it would return locally or at a distance; on the other hand, if you believed too implicitly in a mere local focus which spread and affected the system, you would often be led away into rash and futile operations which could never, in the nature of things, succeed, and which did serious harm by prejudicing certain operations in the minds of the public, both medical and lay. Mr. Banks confessed that our only remedy at present, if we employed any at all, was the knife, and that admittedly a very poor one. He was taught as a student that if there was secondary infiltration of the glands all operative procedure was contraindicated, but about eighteen years ago he had begun to practise a much freer local removal of the breast, together with a clearing out of the axilla, and he believed that if this could be thoroughly done, it was a perfectly justifiable operation. He thought if we could only get people to come early enough with their breast tumours and have them removed, we might save one out of four from further invasion. While, therefore, he deprecated reckless and useless operation, he would regard anyone who should refuse absolutely to remove breast cancers on any consideration as a person perfectly devoid of reason and common sense.

Mr. W. S. CRAWFORD advocated the curability of certain cases of mammary cancer by surgical means. He gave particulars of 4 cases in which the microscope proved the presence of cancer. The first died five years after operation from other causes; a second case was now living, three and a-half years after operation, with no return; a third died three and a-half years after operation from other causes; and a fourth where a different form of cancer had attacked the second breast three years after the first one was removed.

Dr. M'LACH said that, according to some modern "localists," out of 500 operations for cancer, 100 remained free from recurrence; but, according to Sir James Paget, perhaps only one individual would remain free. He was surprised at the meagre information which was supplied by the supporters of hysterectomy for cancer. Surgeons generally complained that patients with cancer were not sent to them sufficiently early; but he believed, with Dr. Davies, that cases of non-recurrence were very seldom examples of early operation.

Dr. ALEXANDER admitted that the results of operation for cancer were not satisfactory; but there could be no doubt that surgery was sometimes a "cure" for the disease. He cited cases from his own practice to prove this point. Apart from "cures," surgery gave distinct relief, especially in cancer of the tongue and rectum, for recurrence generally occurred outside the alimentary tract, and the patient died from exhaustion without the terrible agony experienced by those who died unrelieved by operation.

Drs. and Messrs. BRIGGS, J. D. CRAWFORD, ROBERT JONES, J. WALLACE, CARTER, RAWDON, and RUSHTON PARKER also took part in the debate.

EPIDEMIOLOGICAL SOCIETY.—At a meeting on November 15th, Mr. SHIRLEY MURPHY, President, in the chair, Mr. T. W. THOMPSON, of the Local Government Board, read a paper on Return Cases of Scarletina, or cases occurring within three weeks of the return of a patient from hospital, the number of which varied unaccountably, but was as a rule about 3 per cent. on the admissions. They were popularly attributed to the premature discharge or imperfect disinfection of the patient, but by the hospital authorities to independent sources of infection, as schools, or to imperfect disinfection of the room and its contents, since secondary cases following soon after the first were of frequent occurrence.

Other explanations were that infectiveness persisted after all visible symptoms had disappeared, or that the patient was saturated with the poison from long residence in an infected atmosphere. The frequency of return cases bore little or no relation to the precautions taken at the hospital, appearing to depend rather on the surroundings of the home and on the difficulty of determining when a convalescent ceased to be infectious, cases occurring even after a fortnight's quarantine in a pure atmosphere. Desquamation was generally accepted as evidence, but many high authorities attached more importance to the condition of the throat, etc., though whether chronic and recurrent catarrhs were infective was an open question. Dr. CHALMERS (Glasgow) thought that overcrowding in hospitals tended to increase the persistence of the poison; and Dr. SWERTING thought it favoured the occurrence of albuminuria. Dr. GOODALL considered the inquiry rather one for medical officers of health, since many return cases went to other hospitals, where they were not recognised as such. He was convinced that infectivity often persisted long after all peeling and catarrhs had ceased, leading to return cases, even when months had elapsed, and when neither clothing nor houses were the same. But disinfection as carried out by the sanitary authorities was most unsatisfactory, and the poor were in the habit of evading it in the case of their best clothes. It was, however, impossible to disinfect a person as we could a coat; Nature and time only could eliminate the poison from the system. The discussion was continued by Drs. PARKES, SWERTING, PRINGLE, DOWNER, PARSONS, BOND, BULSTRODE, BUCHANAN, and SIDNEY DAVIES, who supported what might be called the "old clothes" theory, and insisted on the persistence of infectiveness and of the poison in fomites, the influence of school attendance in propagating the disease, and the need for a prolonged investigation into the bacteriology of the skin, throat, urine, etc. Dr. BUCHANAN doubted if cases occurring much later than eight days should properly be considered as "returns," remarking that 93 per cent. of those in Dr. Chalmers's report appeared within the fortnight.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At a meeting on November 15th, Dr. A. SYMONS ECCLES, President, in the chair, the debate on the etiology and treatment of gastric ulcer was resumed. Mr. KEETLEY said that in cases of perforation not diagnosed early enough, it was clear that confusion with colic or stomachache seldom arose, and that though peritonitis was recognised, the mistake was made of not at once determining the cause and dealing with it. Mr. MCADAM ECCLES laid stress on the value of drainage in cases of escape of the gastric contents, and for this purpose he makes a second opening lower down, which he keeps open for twenty-four to thirty-six hours. Dr. CLIPPINGDALE discussed the etiology of gastric ulcer, and assigned a leading place to local constrictions in women by corsets, in men by belts. Mr. SWINFORD EDWARDS raised the question of the value of gastric endoscopy for diagnosis previous to perforation, and narrated a case of a middle-aged man who had a copious discharge of bright red blood from the rectum. No gastric symptom was present, but at the necropsy perforation of the right gastro-epiploic artery was the only lesion found. Mr. R. W. LLOYD discussed the dietetic and medicinal treatment, and called attention to the varied localisation of pain in cases where perforation afterwards occurred. Dr. ALDERSON thought that local counter-irritation was a valuable adjunct to treatment. Mr. BIDWELL referred to the operative treatment in non-perforating cases. He mentioned a case in which operation had been performed for persistent symptoms, and others where the symptoms were due to adhesions either within or without the stomach in consequence of the cicatrization of an ulcer. Considering the uncertainty of the diagnosis of perforation, he held that an operation ought to be performed unless the physician could assure himself that the case was not one of gastric ulcer. Dr. SNAPE asked the opinion of surgeons present as to the advisability of operating in severe cases before perforation. Mr. BUCK CLARKE, in reply, said that in cases of hemorrhage threatening the life of the patient he would follow the ordinary surgical indications,

and cut down on the bleeding point. Dr. ABRAHAM called attention to a singular appearance in Dr. Alderson's case, that is, that the stomach walls appeared microscopically to be infiltrated with cells somewhat resembling those of a pigmented sarcoma. Dr. LAWRENCE urged the value of albuminate of iron. Dr. FRANKSON thought that some cases of gastric hæmorrhage in girls might be assigned to vicarious menstruation.—The President summed up briefly, and regretted that no speaker had been able distinctly to define the various indications for operation.

HUNTERIAN SOCIETY.—At an ordinary clinical meeting on November 13th, Mr. C. J. Symonds, President, in the chair, Dr. F. J. SMITH read for Dr. McDONNELL notes of a case of Congenital Ataxia in a boy, aged 6.—Mr. TARGETT showed a boy, aged 6, in whom he had excised one temporo-maxillary articulation for Ankylosis following Otorrhœa.—Dr. J. H. SEECHEIM showed a case of Nyctagmus with Facial Paralysis in a girl, aged 11, present since the age of 2.—Dr. ETTLES showed (1) a case of Horizontal Nystagmus cured by correction of the astigmatism present; (2) a case of Distraction of the Left Frontal Sinus in a woman of 58; and (3) a case of Hyperexotropia with Divergent Strabismus and without Diplopia.—Dr. FRANK J. SMITH showed a case of Paroxysmal Hemoglobinuria with Local Syncope and Asphyxia.—Mr. O'BENSHAW showed a girl of 17 with Patches of Local Asphyxia on Toes and Heels.—Sir HUGH BRAYOR showed (1) and (2) two cases of Cervical Herpes followed by severe pain, and (3) a case of Fibroid Phthisis of the Right Lung of a boy 4 years old.—A case was shown for Dr. GLOVER LYON of Imperfect Development of the Pinna of the Right Ear.—Dr. COTMAN showed a fireman with peculiar thickening of the Left Ankle, arising from traumatism, but causing no pain or other signs except thickening of tibia and fibula at the joint.

SOUTH WEST LONDON MEDICAL SOCIETY.—The monthly meeting of this Society was held on November 13th, when a paper was read by Dr. CHARLES W. CHAPMAN on Heart Disease in the Young. Stress was laid upon etiology, prognosis, and treatment; and an interesting discussion ensued, in which the President, Mr. T. S. HOWELL, Dr. A. D. ROE, Mr. A. E. DODSON, Dr. B. DUKE, Mr. T. A. J. HOWELL, and others took part.

EDINBURGH OBSTETRICAL SOCIETY.—At a meeting on November 15th, the following office-bearers were elected: *President*: Dr. A. Ballantyne (Dalkeith); *Vice-Presidents*: Senior, Dr. Halliday Crook; Junior, Professor A. R. Simpson. *Treasurer*: Dr. W. Craig. *Secretaries*: Dr. J. W. Ballantyne, Dr. F. W. N. Hamilton. *Librarian*: Dr. R. Milne Murray. *Editor of Transactions*: Dr. J. W. Ballantyne. *Members of Council*: Dr. Lucas, Dr. Menzies, Dr. Stewart Stirling, Dr. Keppie Paterson, Dr. A. H. F. Barbour, Dr. James Ritchie, Dr. Andrew Balfour (Portobello), Dr. J. Jamieson. The President delivered his valedictory address.—Dr. R. C. BUICK (Dundee) read notes on a case of *Astreia Vagina* (with specimen), and Dr. J. W. BALLANTYNE read a paper on Teratogenesis: an Inquiry into the Causes of Monstrosities: Part I, the Theories of the Past.

GLASGOW SOUTHERN MEDICAL SOCIETY.—At the third meeting of this Society, Dr. ALEXANDER RANNIN in the chair, a paper on the treatment of Phthisis Pulmonalis was read by Dr. EDWIN DUNCAN, sketching the line of treatment adopted in 36 cases of phthisis pulmonalis under his care in the Victoria Infirmary during the past 12 months. Excluding 2 cases moribund on admission, of the remaining 34, 4 were cured, 9 greatly improved, 13 improved, 8 remained in *status quo*, and 1 became worse. The most important therapeutic factors were pure air (air washed and filtered before entering the wards) and an equable temperature. Medicinally, counter-irritation and antipyretics (if necessary) in the acute stage; later, frequent inhalations of a mixture of creosote, eucalyptol, and pineol in equal proportions. Internally, carbonate of guaiacol and beechwood creosote, beginning with small doses; 60 to 80 grains of guaiacol were administered four times daily without detriment; and of creosote, 25 minims

in olive oil. Creosote had also been given as a suppository. Pure guaiacol had no advantage over the carbonate; applied to the skin (in 20 in flannel, covered with oiled silk) it brought down the temperature—in one case to 98°, with symptoms of collapse. Phenol was found in the urine when the maximum dose was reached, without impairing the renal function. In one case in which there was acute nephritis, the blood and albumen disappeared while the patient was taking large doses of the carbonate of guaiacol. There was no gastric disturbance with either drug. Where a large cavity existed, intralaryngeal injections of menthol, 15 per cent.; guaiacol, 4 per cent. in olive oil—the patient lying on the affected side—had been employed with benefit. Cod-liver oil and a generous diet completed the measures employed. In replying to the discussion which followed, Dr. Duncan advocated the erection of a hospital in Glasgow by the municipal authorities for the treatment of tuberculous diseases.

ULSTER MEDICAL SOCIETY.—The opening meeting of the session was held in the Society's rooms, Lombard Street, Belfast, on Thursday evening, November 7th, when there was a large attendance of members. The outgoing President, Brigade-Surgeon MCFARLAND, took the chair, and introduced his successor Professor SINCLAIR, F.R.C.S., who delivered an address on the Delimitations of Medicine and Surgery in Diseases of the Abdomen. An analysis of 22 cases of appendicitis occurring in his practice was presented, illustrating every variety of the disease and its treatment, and opinions adverse to the full adoption of the American indications for operation were put forward. Many cases might appropriately be left to the physicians, and the best guide for surgical interference was persistent tenderness. A distinction was made between recurrent cases with intervals of complete remission of symptoms, which inclined to obliteration rather perforation, and relapsing cases in which pain and tenderness persisted throughout the short intervals between the attacks. In these latter cases operation should be urged, as sero-purulent retention was probable and perforation likely. In the former cases it might be left to the patient to decide whether he would get rid of an inconvenient tendency. Referring to the treatment of gall stones, Dr. Sinclair expressed the opinion that this condition was not sufficiently often diagnosed by physicians, or made the subject of operation by surgeons. The treatment of stomach perforations by a transfer of them to the surgeons for operation was recommended, but a similar transfer of typhoid perforations was condemned. Even the prophylactic excision of gastric ulcers before perforation was objected to, on account of the unsatisfactory state of the symptomatology. Physicians should remain responsible for these cases until they perfected their diagnostic methods, and were able to distinguish the anterior accessible ulcers with a perforative expectancy of 85 per cent., which were fair marks for prophylactic excision. With regard to intestinal obstruction, an attempt was made to distinguish those cases which were suitable for operative treatment from those which should remain under medical supervision. Some remarks followed on malignant disease of the stomach and intestines, the latter field presenting more hopeful features than the former for surgical intervention, but the selection of cases of either sort should be made more carefully, and would be found decidedly limited in both. On the motion of Dr. McKENZIE, seconded by Professor BYRNE, a hearty vote of thanks was passed to Dr. Sinclair.—The Society is at present in an active and healthy condition, and the membership undergoes a steady augmentation. Dr. McKENZIE continues to act as Honorary Secretary. The annual dinner takes place on November 28th, in the Grand Central Hotel, Belfast.

NEWPORT MEDICAL SOCIETY.—At a meeting on November 2nd, Dr. A. GAMMON THOMAS in the chair, Mr. O. E. B. MANON read notes of a case of Typhoid Fever of ninety-six days' duration, with relapse, without complication. Dr. R. J. PATON related a case of Rupture of the Gall Bladder; and Mr. H. B. SIDDON one of Cancer of the Pancreas.—Pathological specimens of the latter cases were shown.—Dr. D. R. PATERSON (Cardiff), Dr. T. HOWARD JONES (Newport), and Surgeon-Major ROCHE (Newport) were elected members of the Society.

REVIEWS.

TWENTIETH CENTURY PRACTICE: AN INTERNATIONAL ENCYCLOPEDIA OF MODERN MEDICAL SCIENCE by Leading Authorities of Europe and America. Edited by THOMAS L. STEDMAN, M.D., New York City. In Twenty Volumes. Vol. I, Diseases of the Uropoietic System; Vol. II, Nutritive Disorders; Vol. III, Occupation Diseases, Drug Habits, and Poisons. London: Sampson Low, Marston, and Company, Limited. 1895. (Roy. 8vo, pp. 737. 89 Illustrations.)

The first three volumes of this gigantic undertaking have appeared with commendable punctuality. The editor has succeeded in obtaining the co-operation of many recognised authorities in Europe and America. The time is opportune for a new encyclopædia of medicine, since in recent years, thanks to the opening up of the new field of bacteriology, to the great strides which have been made in neurology, to the increased application of chemistry and physics, to the study of pathological problems, and generally to the greater accuracy with which clinical medicine is now studied, something like a revolution has come about.

Of the seven articles contained in Vol. I six are devoted to those affections of the uropoietic system which are now generally regarded as being within the domain of surgery. In the first of these, which deals with the diseases of the kidneys (surgical) and of the ureters, and includes also the injuries of these organs, Mr. Reginald Harrison states very clearly the present position of this important and rapidly developed branch of surgical work. This article, as might be expected from one who has done so much as the author to promote and advance renal surgery, is based much more on personal experience than on study of the work of others. It is thoroughly practical, and in its instructions as to diagnosis and treatment will be found very valuable. In his remarks on nephrectomy Mr. Harrison declares his preference in most instances of the lumbar over the abdominal method, mainly on the grounds that the former is the safer operation. The latter he would limit to some exceptional cases of floating kidney and of large renal tumour. Doubts as to the existence of a fellow kidney, or to the condition of this organ when certainly present, may now, it is held, be removed or confirmed by practice of the improved methods of electric endoscopy.

In the article on Diseases of the Bladder, also by Mr. Reginald Harrison, the most interesting sections are those relating to traumatic rupture and to the many forms, most of them of frequent occurrence and very intractable, of cystitis. The reader will find here, besides much valuable instruction on practical points, some striking and, it may be, fruitful suggestions. For instance, Mr. Harrison, though acknowledging that in cases of ruptured bladder, laparotomy is the safest course to be pursued, argues that this injury, even when involving the peritoneum, is not under certain circumstances, especially if a free and involuntary exit for the urine be at once provided, necessarily fatal. Again, he sees some hope of ameliorating the wretched state of those suffering from extroversion of the bladder, by establishing a renal fistula in one loin, and afterwards removing the other kidney.

The articles on Diseases of the Prostate and of the Male Urethra by Dr. Lydston, of Chicago, present a very clear and exhaustive review of the present state of knowledge relating to many affections to which American surgeons have of late years paid much attention. On the most recent operation for the relief of enlarged prostate, however, the author has very little to say. He states that he has had no experience of it himself, and he makes no reference to the recorded results of castration in the practice of others. He grants that this treatment is worth consideration, providing the patient's virility has disappeared, otherwise he would prefer to establish a suprapubic fistula, with or without operation on the prostate proper. The practitioner is recommended to exercise the greatest circumspection before performing castration, lest he incur trouble of a medico-legal character. As gonorrhœa—here called gonococcal urethritis—is fully discussed, together with its complications, we are led to anticipate that

in this work no special article will be devoted to the subject of venereal diseases.

Mr. Hurry Fenwick's article on Diseases of the Urine is a very able and original contribution to clinical surgery, and is likely, when used either for close study or for reference, to be of great service in enabling the practitioner to determine the relative value, with regard to diagnosis, of the different morbid conditions of the urinary secretion. It seems to throw much light on many points hitherto more or less obscure in the symptomatology of both renal and vesical disease.

The volume concludes with a relatively brief but very instructive article on Diseases of the Female Bladder and Urethra, by Dr. Howard Kelly, who, from his well-established reputation, and his position at the Johns Hopkins University, is exceptionally well qualified to write on this subject.

Volume II deals with Nutritive Disorders; it contains articles on some of the more important diseases resulting from a faulty metabolism, and is divided into seven parts, each by a separate author. The volume contains 725 pages, and has a good index, by which reference is facilitated. It opens with a short paper from the pen of Sir Dyce Duckworth, on Addison's Disease and other Diseases of the Adrenal Bodies. That this is well up to date is shown by its referring to the important work lately carried out by Professor Schäfer and Dr. Oliver on the effects on animals of injecting into the veins the extract of the adrenal bodies and its possible future value in treating diseases which are the result of destruction of the adrenals. The article on Diabetes Mellitus is written by Dr. von Noorden, and the German version has already been reviewed separately in the *BRITISH MEDICAL JOURNAL* of November 9th, 1895, p. 1168.

Dr. MacLagan has treated in a most masterly manner the subject of Rheumatism. After discussing carefully the various theories as to its causation, he shows how it can no longer be looked upon as a disease resulting from excessive formation of lactic acid or its accumulation in the system any more than as of neurotic origin, our present knowledge leading us to believe it to be miasmatic, much in the same manner as malaria. In describing the symptoms he shows how the present generation of practitioners are unable to realise the agony formerly suffered, the disease being so much under control by salicyl compounds. The drug should be given early, and pushed in large doses until all pain has ceased. In cases in which there is danger of heart failure salicin is to be preferred.

Gout is next taken up by Dr. Lyman, who gives us a very complete summary of the disease. He lays special stress on those signs that characterise the arthritic diathesis, and the treatment is well dealt with.

To Dr. Archibald Garrod has fallen the difficult subject of Arthritis Deformans. He points out how it is to be distinguished from gout and rheumatism, and that in its causation heredity seems to play a very small part. Since it attacks specially persons who are "run down," he recommends that the treatment ought to be principally tonic, though attention to hygiene is of the greatest importance, while the diet must not be restricted as in gout as regards animal food. Any treatment to be of any use must be persevered in for a long period of time before results can be hoped for.

The article on Diseases of the Muscles is from the pen of the late Dr. Dujardin-Beaumez, who shows how they may often be affected, but the occurrence overlooked by other symptoms masking their condition. This article is admirably written, and, dealing with a subject which has hitherto received little attention in systematic works, is worthy of most careful perusal.

Dr. Oertel concludes the volume by a paper on Obesity, which is an excellent summary of his method of treatment.

The extent of the subjects has prevented the authors from giving complete summaries of the literature, but as a work of reference for the busy practitioner who desires to know present views rather than an historical summary it will be of the greatest service.

The memoirs included in Volume III are of a miscellaneous character, and, viewed together as a whole, savour rather of the student's midnight oil than of the atmosphere of hospital wards, factories, and workshops. This remark does not

apely to the essay by Dr. Norman Kerr, who records his matured opinions and observations, the fruit of lifelong study and research, on Alcoholism and Drug Habits. Under this latter designation is collected a mass of information not to be found in any other treatise. He is an anti-alcoholic enthusiast, and his decided views must therefore be taken with some reserve. Dr. Kerr occupies the only place accorded to British authorities in this bulky volume. All the other writers, except Dr. von Liebig of Munich, are physicians practising either in the United States or in Canada. Their contributions are marked by careful study and thoughtful consideration.

To enumerate the subjects dealt with, they are Shock and Collapse, by Dr. Shredy, Surgeon of Hospitals in New York; Sea Sickness, by Dr. Gibson, Medical Director, United States Navy (to whom are also assigned the short essays on Heat Stroke and Frostbite); Osteomalacia, by Dr. Cunningham, Professor of Pathological Anatomy, Harvard University; Mountain Sickness, by Dr. George von Liebig, Docent of Ophthalmology and Pathology, University of Munich; the Diseases of Occupations, by Dr. J. Hendrie Lloyd of Philadelphia; Vegetable Poisons, by Dr. Small of Ottawa; and Poisoning by Mineral Substances, by Dr. James Stewart of Montreal, Professor of Medicine, McGill University.

It will be noticed that some of these subjects have not received a place or anything like equal attention in many medical works, and therefore merit study as special monographs. Where they are written by experts they will secure this consideration. To write a really satisfactory essay on diseases of occupation, there is needed a special study of those maladies in connection with their causes as met with in factories and workshops, in processes of manufacture, in the surroundings and habits of operatives, in the structural arrangements and sanitation of places of work, and other details which must be examined in order to assess their effects upon health and life. Great credit is due to Dr. Lloyd for the industry and research spent in collecting information on the matters he deals with, and to his erudition and skill in critically examining and commenting on the facts and opinions he has brought together. He, however, candidly confesses that he does not write from original research respecting industrial diseases and their causes, but that his article is mainly the product of the study of some of the principal authors who have produced special treatises on trade diseases, though he has appended whatever facts hospital or other practice has afforded him.

There is one section of the article which will be of interest to all concerned in devising and amending factory legislation; this is the one which contains a summary of the enactments regulating labour in several of the most important States in the Union. Each State makes laws for its own internal economy, and consequently there are great variations existing among their legislative provisions and administrative details. With regard to the factory laws now enforced in many States, the general deduction is that, on the whole, they are more rigid and far-reaching than those in force in Great Britain, though probably less effectively administered by the authorities.

GOV'S HOSPITAL REPORTS (FOR 1894). Vol. II. Edited by E. C. PERRY, M.A., M.D., and W. H. A. JACOBSON, M.A., M.Ch. London: J. and A. Churchill. 1895. (Pp. 272.)

This volume, just issued, contains thirteen papers of varying interest and importance. Dr. Pye-Smith relates a case of Bilateral Paralysis of the Facial and Auditory Nerves, probably of syphilitic origin, though not materially benefited by iodide of potassium gradually increased to 120 grains a day. In a paper on Empyema following Lobar Pneumonia, Drs. W. Hale White and A. Channing Pearce state that empyema has been a more common sequel of lobar pneumonia during the last few years than formerly; and that, as regards treatment, aspiration is futile, and the chest should be incised and drained. Dr. Theodore Fisher contributes an exhaustive paper on Hypertrophy of the Heart without Gross Organic Lesion, and agrees with Boilingier that over-indulgence in alcohol is a common cause of the affection. Dr. Meadows Turner contributes from the North-Eastern Fever

Hospital a careful article on Scarlatinal Nephritis and its varieties, and remarks that chills can hardly account for the large percentage of nephritis, especially as in the majority of cases the complication develops whilst the patient is in bed. He examines other suggested causes of the disease, notably constipation, and fails to find one that holds in every case.

Mr. Bryant contributes an abstract of an address on Temperature after Operation, delivered in 1879, and hitherto unpublished. The author sees no reason to change the opinions he then entertained, but incidentally remarks that he now uses less opium after operations, in the belief that opium checks repair. Mr. L. A. Dann gives an interesting sequel to a case of Fractured Pelvis with Ruptured Urethra; and in a second paper describes a case of Multiple Atrophying Sarcoma of the Head and Neck. Mr. G. B. Smith (Surgical Registrar), in a paper on the Question of Amputation, in Senile Gangrene, based on a study of forty-eight cases, concludes in favour of amputating high up (through or above the knee) in all such cases, thus supporting the views of Mr. Jonathan Hutchinson. Dr. John Fawcett gives the results of an investigation on the Value of Piperazin, and concludes that the drug is almost useless as a solvent of uric acid stones, or in the treatment of gout. Mr. Newland-Pedley writes on the treatment of (1) Suppuration of the Maxillary Antrum (for which he advocates a permanent opening into the mouth to abolish retention of inflammatory secretions), and (2) Extreme Cases of Congenital Cleft Palate by Obliterators and Vela. Dr. J. F. W. Silk, in a paper on the Administration of Gas and Ether, remarks that "no method (of anaesthesia production) requires more constant practice, in order to maintain and develop the skill already obtained;" he, however, considers the combination of nitrous oxide and ether as "a most valuable addition to our list of available methods of producing anaesthesia." A list, by Drs. Shaw and Perry, of specimens illustrating the Pathology of the Liver and Gall Bladder, and which were added to the Museum in 1894, is appended.

DIAGNOSTIK DER KRANKHEITEN DER BAUCHORGANE. (Diagnosis of Diseases of the Abdominal Organs.) By Dr. HANS LEO. Zweite Auflage. Berlin: A. Hirschwald, 1894. (Royal 8vo, pp. 530. With 45 illustrations. Mll.)

This work by Dr. Leo is divided into two parts, the one dealing with the physical examination and clinical characteristics of the various diseases and the other with the chemical, microscopical and bacteriological examinations now required in the investigation of such diseases. Diseases of the generative organs are not included in this book. Each section in Part I. is again divided into a general and special part; in the former a short account of the symptoms and examination of each organ is given in general, and in the latter the symptoms and course of each particular disease, with the physical diagnosis, are detailed. In Part II. the examination of the secretions of the mouth, stomach contents, faeces, urine and fluids obtained by puncture is described. This examination is given in considerable fulness, and the author's reputation lends to some parts a more than usual importance. Under bacteria, the tubercle, cholera and typhoid bacilli receive a careful description. This book may be cordially recommended. It illustrates the fruitful results obtained in modern times by that union of clinical and laboratory investigations, which in no respect interferes with the practical character of the clinician of to-day.

MRAZOLA PARANESTHETICA. By Dr. W. K. ROZIN, of Moscow. Berlin: S. Karger. London: Williams and Norgate. 1894. (Demy 8vo, pp. 24. 9d.)

Under this name the author describes, with fourteen illustrative cases, an affection characterized by painful sensations in the outer side of the thigh, and accompanied by a subjective and sometimes objective anaesthesia. The pain is mostly of a burning character, and is worse on standing or walking. The paraesthesia and anaesthesia are limited to the distribution of the N. cutan. femoralis ext., but the burning sensation may extend beyond it. The progress of the disease is slow,

and considerable improvement may be obtained by treatment.

The author discusses the etiology of this complaint, which he looks upon as being due to a lesion of the abovenamed nerve. Some of the author's cases have been under observation for so long a time as to preclude the notion that this neuralgia is only an early symptom of some spinal cord lesion. The reviewer himself has knowledge of a case extending over more than fourteen years, which, although more intense, corresponds in many particulars to the description given by the author. Dr. Roth's monograph is interesting, and may call attention to an affection which may have been either overlooked or put down to some lesion of the spinal cord.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

AN ASEPTIC SPONGE HOLDER.

DR. R. W. FELKIN, of Edinburgh, has designed a sponge holder, which may also be used for cotton wool, which he believes will overcome the difficulty encountered in cleansing the ordinary sponge holder, and also the further difficulty often met with of removing either the sponge or cotton wool from the holder. The form of the holder is shown in the accompanying drawing. A thread attached to the sponge or swab is passed through the cup, drawn tight, and held in position by a turn round the catch near the handle. Any number of sponges or swabs can be used in turn on one holder, which Dr. Felkin believes will be of use in treatment of diseases of the throat, the abdomen, and in gynaecological work. The holders are made in various sizes by Messrs. Hilliard and Son, 7, Nicholson Street, Edinburgh.

EMBEDDED ELECTRIC LIGHT.

We have had submitted to us a set of instruments for examining the throat, rectum, vagina, etc., in which the illumination is obtained from small electric lamps of about four or five candle power embedded in the instrument. The apparatus has been designed by J. W. Daily. The current to each lamp is supplied by means of wires placed in channels cut in the handles, etc., and communicating with a small portable battery. The lamps being embedded in the metal bound cavity of the wall or jaw of the instruments, and covered by a carefully sealed transparent plate of mica, cannot be broken, and do not obstruct in any way the view in the examination of cavities, nor prevent the free use of instruments. The special advantage claimed for this adaptation of the electric light is security against breakage, in addition to brilliancy of illumination and steadiness and general convenience of use. The apparatus can be seen on

application to Mr. T. H. Batten, of 3, Adelaide Place, E.C.; or to Mr. T. E. Harris, Throgmorton House, Cophthall Avenue.

ANTINONNIN: A DISINFECTANT AND PARASITICIDE.

ANTINONNIN is the trade name for the potash salt of orthodinitro-cresol, one of the yellow cresol colours prepared by the Farben-Fabrik (Normals, Bayer and Co.) at Elberfeld. It is claimed to be a powerful bactericide and a complete protection against the dry-rot fungus, mildew, etc., and as being available for both woodwork and masonry. Professors Harz and Von Miller have found it to be a powerful antiparasitic, especially effective against *liparis monacha*, the caterpillar destructive to trees, and most plant parasites. It is more active in a soap solution, and can be employed in quantities varying in proportion from 1 in 2,000 for plants to 1 in 100 for the prevention of dry rot. It has also been found most efficacious in preventing fungoid growths on the walls of breweries, distilleries, etc., and as a remedy in skin diseases

caused by animal parasites. Antinonnin is a yellowish paste, somewhat readily soluble in water, forming a bright yellow solution, and in the proportion of 1 per cent. we have found an aqueous solution to be a powerful agent in preventing fungoid growth, although its use is somewhat restricted on account of the yellow stain imparted to everything impregnated with it. Antinonnin has the advantage of being inodorous and non-volatile, although like many other powerful bactericides it is poisonous. The English agent is R. Simon, Zulia Road, Nottingham.

A PARACENTESIS NEEDLE FOR USE WITH HYPODERMIC SYRINGE.

DR. WILLIAM R. HUGGARD, of Davos Platz, sends us the following description of a paracentesis needle, which he has now used for some years, and which has been made for him by Messrs. Arnold and Sons, London.

The instrument has one arm for a hypodermic syringe, and another arm to which india-rubber tubing can be attached; the central tube carries a fine needle. The advantage of the little contrivance is that a very small and not alarming instrument is used for the exploratory puncture, and that fluid, if found, can be removed at once. The instrument having

been carefully sterilised, the trocar in place, the stopcocks open, and the syringe filled with hot water, the water is driven through the instrument till only a drop or two remains in the syringe. The arm for the india-rubber tubing is now closed by the stopcock, the puncture made, the needle withdrawn, and the central stopcock closed. The couple of drops of warm water remaining in the syringe, if now pressed out, will sufficiently dilute any thick fluid that may be found to allow it to flow through the needle when the piston is withdrawn. If fluid is found, the india-rubber tubing connected with an exhaust bottle can be attached at once. Should the needle get blocked, the simplest way to remove the obstruction is by injecting a little warm water from the hypodermic syringe, which, of course, should have again been sterilised.

THE TREBLE SPRING TRUSS.

DR. HERWOOD SMITH (Harley Street, W.) writes to point out that the truss described on page 1248 of the *BRITISH MEDICAL JOURNAL* of November 16th appears to embody the same principle as the pelvi-belt designed by the late Dr. Protheroe Smith, the fixings being improved by doing away with screws. The method of hinging the springs and adjusting the iron pads are, he thinks, the same in principle.

REPORTS ON THE NURSING AND ADMINISTRATION OF IRISH WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

IX.—DONEGAL WORKHOUSE INFIRMARY.

Our visit to the Donegal Workhouse was made in a down-pour of rain, such as is common on the west coast, where the hills condense the rainclouds as the air comes laden with moisture from the Atlantic. The house stands on the line of march between Stranorlar and Ballyshannon. The Board has given discretionary power to the master to refuse relief to the tramps, and the relieving officer simply passes them on to the house for the master to deal with. The result of this plan is, so we were told by the master, that the tramps do not apply at the house. Having an introduction to the medical officer, Dr. Pope, we met him by appointment at the workhouse.

THE HOUSE IS A SMALL ONE, a fourth-class house, and was very empty at the time of our visit; 84 was the number of inmates all told, and of these 30 were on the medical relief book (28 in hospital), not including the lunatics, so that more than half the inmates are disabled paupers. We were not surprised to learn that it is sometimes necessary to obtain labour from outside, the master being empowered to hire when requisite. No ground is cultivated, with the exception of a few flower beds in front of the house.

THE LUNATIC WARDS

on the male side were empty. The cells are used in this house, two females sleeping in one cell; there were two most sad cases in box beds, semi-idiotic semi-paralysed women, entirely helpless. The three patients who were up, epileptics, were seated on a bench against the wall of the corridor into which the cells opened; at one end is a protected fireplace, and at the other the door that opens on to the airing court. These patients are under the care of a pauper; they had an unwashed, untended appearance. The cells are dark and ill-ventilated, the corridor is merely a dreary passage giving access to the cells, yet this is all the accommodation provided for these unhappy creatures. Only last year the Inspectors of Lunacy commented in the severest manner on this disgraceful state of things. We quote from the report:

"We are compelled to reiterate the opinion that the condition of the lunatic inmates is far from satisfactory. The most helpless are frequently found ill attended to, the only persons to look after them being to a large extent pauper inmates; the apartments allocated to their use are often dark, ill-ventilated, and badly furnished, whilst the means of securing personal cleanliness are very inadequate. . . . Unfortunately in nearly all the Irish workhouses the inmates of the lunatic wards are found to be the most helpless imbeciles and demented, who, quite incapable of caring for themselves, unable to wash, feed, or dress themselves, and requiring the most constant and careful supervision, are left to the mercy of a pauper inmate, or, where a paid attendant is attached to the ward, to the care of an official usually ignorant and untrained, and very often negligent of his duty."

These strong words of an official qualified to speak are not too strong to represent the condition of the unhappy pauper lunatics at Donegal. The poor idiots made such an impression on us that we have spoken of them first, but we must not forget

THE SICK,

who are in wards on the two floors of the hospital building. These wards, two on each side of the middle block, hold seven and eight beds respectively; in the lower a wooden screen acts as a draught protector between the beds and the door. The structure exhibits the usual characteristics of

these primitive hospitals—the whitewashed walls, which are so wearying to the eyes; pitched roof with bare rafters, where the dust gathers and forms a soil for the germs of disease; small, ill-fitting windows on one side, faced by slit openings in the opposite wall, admitting the weather but not ventilating the ward; old fireplaces which waste fuel and are niggardly of heat; these are the conditions which surround

THE PATIENTS.

There was one bad case of paralysis—a woman with entire loss of power. She was in a box bed on straw, and we noted that the poor thing was in a most uncomfortable and insanitary condition. A young woman with synovitis was waiting for a leather splint; a man, who appeared to be in an advanced stage of phthisis, was seated by the fire; he had been a soldier, but had not served long enough to earn a pension. The other patients were chronic or old age cases. One case in especial roused our compassion: a respectable-looking woman, who had been in good service in London, was, by the Act of Settlement, returned with her child to face the horrors of an Irish workhouse. The infant was ruptured, and this fact detained her in the sick ward. The look of utter hopelessness in her face will not soon fade from our recollection.

THE BEDS

in the infirmary are almost all wire wove, with hair mattresses; easy chairs do not exist; we saw a wooden chair on which was what appeared to be an old car cushion, and there was of course the usual bench. The bedsteads are too close together, and there was no room for tables in the wards. As there are no day rooms the patients live all day in the wards, as well as sleep in them, and the cubic space was quite insufficient.

THERE IS A TRAINED NURSE

in the hospital, but no night nurse; in each ward there is the pauper wardman or woman, the only assistants that the nurse has. The nurse is also held responsible for the care of the lunatic class, whose quarters are in her division. She is sorely handicapped by the conditions of her work; she has no separate linen store, no water laid on, either hot or cold; the only means of heating water is in a kettle. The water comes from the river, and is pumped into tanks by the inmates. The fireplace in the infirmary kitchen is a wide-mouthed wasteful grate, which makes almost all cooking extremely difficult.

AT NIGHT

in the sick wards the vessels are left unemptied, and the patients have no help but such as they can render each other. It is therefore more than probable that the poor paralysed woman is left uncleansed all night. Both Dr. Pope and the nurse said that the atmosphere in these wards is very foul in the night. When we think of the fate of these unhappy sick, left all night without nursing of any kind, in the dark and fetid ward, we cannot but condemn the system which allows so much preventable suffering. This is no sensational picture; its worst features can be verified by any inhabitant of Donegal for himself.

THE INFIRM CLASS

is a small one in this house; the men's dormitory was empty, the few men being engaged in the house; in the female ward there were thirteen beds, all filled. The narrow beds are used in both wings, with straw ticks and pillows. (We confess to a desire to condemn every Irish Board of Guardians to spend a night or two in the infirm ward of their own workhouse, the door being locked as usual on the outside, at 7 in the evening.) It is always a matter of surprise to us that these straw-filled ticks have found favour for so long with the authorities; they are neither economical nor suitable; the substitution of mattresses would soon be paid for in the lessened amount of the straw bill. The women were all in the dormitory, the dayroom not being in use. The ward was comfortless and dreary; a window at either end gave but a poor light and insufficient ventilation to the long, low-pitched room; an old fireplace, for either turf or coal, in the middle of the long wall, was the only means of heating the dormitory. The benches (the only furniture) gave no suggestion of rest or comfort; many of the inmates sat on the feet of the bed. A basin or towel for the whole ward is the sole means of cleanliness provided.

The nursery has been closed for some time; the confinements (about one a year) take place in a small ground-floor room in the infirmary.

THE DIETS

consist of potatoes five days in the week, and soup on the other two days, in the body of the house; in the infirmary, meat, milk, soup, and extras, as ordered by the doctor. Corn flour is the diet of the infants, so that it is as well that the nursery is empty—at all events till a more flesh-forming food is ordered for those under 2 years of age. The food is cooked in a kitchen fitted with three coppers, each having a separate furnace, a plan which is wasteful alike of fuel and labour. These kitchens are relics of famine days, when porridge or soup was cooked in gallons to feed the starving population. But this is half a century ago, and perhaps it might be well to remove them now to make way for something more suited to the requirements of the house. The laundry is of the same date, and has the same old-world aspect; no hot water is laid on; there is no mangle or other labour-saving appliances except a wringer, of which one roller is practically useless.

RECOMMENDATIONS.

We would call the attention of the Board to the words which we have quoted from the report of the Inspectors of Lunacy, and urge them to remove this disgrace as far as Donegal is concerned, by making the quarters of the idiots less cruelly unsuitable, and providing them with proper attendance. If it is right to retain this class in the work-houses at all, the guardians are bound to do all that is possible for their treatment. Further, we suggest the appointment of a trained night nurse for the wards, to remove the scandal of the present untended condition of the sick through the night. Lastly, it seems to us that a well-devised scheme of amalgamation would solve many of the difficulties which beset the guardians. We trust that this matter will soon receive the attention of the central authority, for the guardians require all the advice and assistance possible in this difficult task of bringing the houses up to date.

We are glad to see that the report on the Derry Workhouse Infirmary by the Special Commissioner of the BRITISH MEDICAL JOURNAL, appointed to investigate the condition of Irish Workhouses, is reprinted in full in the *Irish Times*. We feel greatly indebted to our contemporary for the daily press and the public press in Ireland, for the publicity which they are giving to these detailed reports and to the recommendations contained in them, and we earnestly hope that they will so influence public opinion and work upon the good feelings of the guardians, as to continue to bring about early and substantial improvements.

LITERARY NOTES.

Mr. WILLIAM ANDREWS, of Hull, has nearly ready for publication a work entitled *The Doctors in History, Literature, and Folk Lore*. "Chaucer's Doctors of Physic," "The Doctors Shakespeare Knew," "Barber Surgeons," and "Body-Snatchers" are among the subjects treated of by Mr. Andrews.

The first edition of the novel, *The Combe Park Tragedy*, by the daughter of Dr. Long Fox, the ex-President of the British Medical Association, was bought up on the first three days after publication. Miss Edith Long Fox is to be congratulated on its success. A second edition is in the press.

The *Archives of Pediatrics*, now edited by Dr. Floyd M. Crambail, adjunct Professor of Pediatrics in the New York Polyclinic, will be enlarged with the first number of the New Year.

The *Revista de Ciencias Medicas* of Havana of September 20th contains a report by Professor Aristides Mestre of the first case of acromegaly observed in Cuba. The patient is a man, aged 53, a native of Spain.

The *Indicendance Médicale* is the name of a new medical journal which has recently appeared in Paris under the editorship of M.M. Samuel Bernheim and Emile Laurent.

The *Revista Medico-Legal* is the name of a new periodical devoted to matters of medico-legal interest, the first number of which appeared at Bahia on September 1st. It is published under the auspices of the Society of Forensic Medicine of that city, and is edited by Professor Nina Rodrigues.

The *Archives des Sciences Médicales* is the title of a publication which is about to appear under the direction of Professor

T. Joneasco, of Bucharest, with the collaboration of Professors V. Babes and N. Kalendero, of Bucharest, and of a number of leading men in the profession throughout Europe, among whom may be mentioned Dr. Ferrier, Mr. V. Horsley, and Mr. Treves, of London; M.M. Berger, Bouchard, Brouardel, Cernil, Le Dentu, Dieulafoy, Matthias Duval, Grancher, and Pozet, of Paris; Professors Czerny (of Heidelberg), Mikulicz (of Breslau), Nothnagel (of Vienna), and Waldeyer (of Berlin); Professors Maragliano (of Genoa), and Ramon y Cajal (of Madrid), and others. The periodical, which is to be the organ of the Institutes of Anatomy and Surgery and Pathology and Bacteriology of Bucharest, will be published in French, and is intended to be international in character. The Roumanian Government has promised a subvention.

A selection from Billroth's correspondence has just been published (*Hahn'sche Buchhandlung, Hannover and Leipzig*). The letters are interesting as showing the great surgeon as he was known to his intimates—a man of enthusiastic temperament, exquisite artistic sensibility, and the loftiest ideals.

Under the title *In My City Garden*, by "George Umber," Mr. Alexander Gardner will publish, towards the end of the present month, a volume of essays from the pen of Dr. Findlay, a well-known medical practitioner in Glasgow, which will be illustrated by his son, Mr. William Findlay.

We have received the first number of the *Archiv für Verdauungs-Krankheiten*, a new quarterly periodical, dealing, as its title imports, with diseases of the digestive apparatus and with disturbances of metabolism generally. It is edited by Dr. J. Boas, of Berlin, and the names of Professors Leichtenstern (Cologne), von Mering (Halle), von Noorden (Frankfurt), Penzoldt (Erlangen), and Riegel (Gießen), among others, appear as collaborators. As far as printing and paper go, it presents a creditable appearance, and its contents do not belie the promise of the title page. Messrs. Williams and Norgate are the publishers in this country.

The old-fashioned naturalist has almost died out, but Mr. W. J. C. Miller, B.A., the Registrar of the General Medical Council, remains to show us what were his delights. In a charming article in the November issue of *Nature Notes*, he has discussed the jackdaw and his habits, resenting somewhat the frivolous treatment which that bird has met with from most novelists and poets. While willing to admit that the jackdaw is jocular, Mr. Miller claims for him that in qualities of mind he excels all birds, as other birds excel him in melody. The paper is entitled *The Home of the Jackdaws*, and contains a description of a wonderful south coast bay frequented by jackdaws in large numbers, and by certain "wise" men who love a peaceful and quiet holiday.

In a recent number of the *Zeitschrift für Aegyptische Sprache* (Band 23) Georg Ebers propounds a solution of a problem which has long puzzled the learned. Old medical receipt-books, both English and German, contained, down to the very end of last century, the formulae, if they may be so termed, of remedies which are found in ancient Egyptian papyri. The problem is, how did these prescriptions find their way from Egypt to Europe? Clearly not through the Greek writers, since their works contain nothing of the kind. Ebers suggests that they were handed down by the famous old school of Salerno. The teachers in that school are known to have been acquainted with Egyptian medicines through Coptic and Arabic translations. One of the most celebrated of them, Constantinus Africanus, had visited Egypt, and he "conveyed" a good deal of the medical lore which he learnt there into his own writings. Ebers gives a number of examples, showing how recipes for eye lotions, methods of treating prolapse of the womb, predicting the sex of an unborn child, etc., which appeared in old English and German books, could be traced back to Egyptian sources.

In the *Journal of Mental Science* for October, Dr. H. Kornfeld has an interesting little paper on the insanity of love as portrayed in the *Orlando Furioso* of Ariosto. No one, he holds, has better sung the madness engendered by love than the great Italian poet, who shows that love is the very opposite of hatred of life, that it is the best and highest of human feelings. The essential point in Ariosto's teaching is, we are told, contained in the question which he leaves to his readers to answer, "What is more expressive of madness than the undoing of self to ruin others?"

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 490, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, NOVEMBER 23RD, 1895.

THE LONDON CENSUS IN 1896.

ALL who are interested in the health and sanitary condition of London have cause for satisfaction in the fact that under the provisions of the London (Equalisation of Rates) Act of 1891 a census of the resident population of the administrative County of London will be taken at the end of March next. It will then be five years since the last national census was taken, and although the rate of increase of population in the metropolis, taken as a whole, has not in recent years showed any strongly-marked fluctuations, the changes in the movement of population in its several sanitary areas varies so widely that a census once in five years is urgently needed, in order to give that trustworthiness which is so essential to the value of local vital statistics. The specific object for which the census is to be taken is to ascertain the number of persons present within each parish on the census night, in order to enable the Registrar-General to estimate annually, with some approach to accuracy, the population of each parish during the last half of the inter-censal period of the ten years 1891-1901. It is enacted that the census is to be taken under the provisions of the Census (England and Wales) Act of 1890, including its penal provisions, subject to such modifications as may be prescribed by the Local Government Board for the purposes of the Equalisation of Rates Act.

It is clear that while the letter of this Act only provides for ascertaining the number of the population in each parish, something more than a mere count of heads must be taken if adequate means are to be provided for securing an accurate result and for detecting inaccurate returns. Hence the importance of the decision, which will soon have to be made, as to the precise information to be required from the London householder in the census schedule to be used next March.

The London County Council, by whom the cost of the approaching census, to be certified by the Registrar-General, will have to be paid, are naturally anxious to enlarge the scope of the inquiry as widely as possible, and thus to secure the fullest possible statistical information concerning the present population of London. While, however, we are clearly of opinion that the intention of the Equalisation Act was that the census should be an essentially simple inquiry compared with the usual decennial census, we are in the fullest sympathy with the resolution passed at a recent meeting of the Council of the British Medical Association, which recommended as essential that the "name, sex, and

age" of each person present in London on the census night should be recorded. It may probably be somewhat difficult to assert that the ages of the population are strictly essential for the precise object of the Act, but we should regard their omission as a deliberate waste of a golden opportunity for recording statistical information which is of the first importance from a sanitary and public health point of view.

We can scarcely conceive that the Local Government Board, when they prescribe the necessary modifications of the Census Act of 1890, and the precise form of the Householders' Schedule to be used in London in March next, will decline to insert an age column, without which the information to be collected will be bereft of its principal value for medical officers of health and sanitary authorities.

The London census next year is the first experiment in this country in the direction of a quinquennial census, which has long been the dream of medical officers of health and vital statisticians, and which has for a long series of years been steadily advocated in these columns. We shall therefore watch the experiment with great interest, which would, however, be seriously lessened should the inquiry neglect the question of age. If, however, the inquiry include the three essentials of "name, sex, and age," and should the expenses of the inquiry not be unduly increased by further additions, we shall look forward with confidence to this London census being the forerunner of a general quinquennial census in the United Kingdom. Such a census is seriously needed in large towns, and the object in view would be most easily promoted by a short Act, passed early next next session, enabling any local authority to require a census to be taken by the Registrar-General within the district under their control during the year 1896, on similar conditions to those which are to govern the London census, including the payment of the expenses of the census out of the local rates. An Act with optional powers of this description would prepare the way for the inclusion, in the decennial Census Act of 1900, of provisions for a general and simple quinquennial census in 1906.

THE SOLDIER'S BOOT.

IN the report on the New Forest manœuvres by the Duke of Connaught it is stated that footsoreness was very prevalent among the infantry. There were 824 cases of blistered feet on the march to the Forest, 114 cases during the manœuvres, and 19 on the return march. The causes assigned are the defects of the regulation boot, and the want of pliability in the leather leggings. Perhaps too much is sometimes expected of a military boot. It must be cheap but durable. Made in a limited number of sizes, it must fit an almost infinite variety of feet. The young soldier—and most of our soldiers are very young—does not know the importance of carefully determining at first which of the thirty-two sizes (eight of length and four of breadth) in which the boots are made is nearest the shape of his feet, and sometimes he does not get much encouragement to do so, nor does he know that a creased or badly darned sock will surely cause a chafe. Distorted toes, corns, bunions, and ingrowing toenails, all of them the results of badly fitting boots and fruitful causes of footsoreness, do not receive the attention they deserve; while even such details as the cleanliness of the feet and socks are but too often neglected. Various

means have been used with more or less success to harden the feet, such as bathing in solutions of salt and alum, the application of ointment containing tannin, and various powders, a principal ingredient of which is generally salicylic acid, while soaping the feet or socks is recommended by some. There is not much to recommend the method in vogue in certain German regiments of using soft rags instead of socks, nor the French method of dispensing with them altogether.

In a normal foot which has not suffered from bad boots the great toe in standing or walking spreads slightly inwards, its inner border making an angle with the inner border of the foot, and leaving a gap between it and the second toe; the second toe is the longest; the joint of the great toe forms a distinct bulging both outwards and upwards as well as downwards; and a considerable part of the sole, corresponding to the arch of the foot, does not touch the ground in walking. Further, in walking, the chief movements of the foot take place at the ankle and tarso-metatarsal joints.

In the ammunition boot the inner border does not allow the great toe to spread sufficiently inwards, and in many cases presses too tightly over the joint. The longest part of the boot is in its centre, instead of being opposite the great and second toes, and the "waist," or that part corresponding to the arch of the foot, is thick and unyielding, allowing little movement at the tarso-metatarsal joint. Blisters and excoriations are particularly liable to occur on certain parts. Those on the sole can hardly be attributed to the shape of the boot, while those over the middle joints of the smaller toes are generally due to the boots being too short and the toes consequently fixed; but excoriations are also common at the inner and outer sides of the feet over the metatarsal bones, and are due to a defective seam joining the "side lining," probably a useless addition to the boot. Similar excoriations are caused a little further back by the seam joining the "quarters" or side pieces to the front. If this seam were vertical instead of oblique, it would be shorter and would press less on bony parts. At the same time the boot would be more durable, as the extremity of this seam is one of the first parts of the boot to give out. To avoid all sources of friction over the instep a boot which has a great deal to recommend it has been introduced into some European armies in which the lacing is rather to the outer side. A boot can be made in this way with the whole of the upper of one piece of leather, and only one short seam on the outer side. There is certainly a good deal to recommend this method.

Blisters are common on the heel from too much play being allowed, owing to the hard leather not adapting itself to the narrow part between the malleoli and the heel; if the quarters were made of thinner, softer leather this would be avoided, while more play would be given to the ankle-joint, which is too much restricted by the present boot; and nothing would be lost in durability, as these parts have not hard wear, and outlast the other parts. The stitching in two lines at the back of the heel to fix the stiffening is often a source of blisters.

The leather, from constant application of blacking, in time loses all the suppleness it may have possessed; but if appearance could be sacrificed to utility, apparently a great

difficulty in all matters connected with soldier's clothing, and grease or dubbin used instead, while at the same time if thinner waists and lighter leather were used for the quarters, the boots would be sufficiently supple.

The weight, also, is excessive; a pair of the "winter issue," which are shod with nails, for a man of average size weigh $4\frac{1}{2}$ lbs. Besides adding to the fatigue of the feet, since a second pair is carried in "marching order," $8\frac{1}{2}$ lbs. in boots alone is a serious encumbrance. The French infantry at present have a very serviceable boot, weighing about half this. If the alterations in the leather for the quarters and waists were made, together with thinner iron tips and heels and fewer nails, an appreciable diminution in weight would be achieved.

While pointing out certain details in which the regulation boots might be improved, we do not wish to imply that they are altogether defective, for we are aware that they are not infrequently selected by officers as shooting boots in preference to others, nor that by introducing these improvements footsoreness would become a thing unknown; but an improved boot, in conjunction with care as to other points to which we have drawn attention, would materially lessen the number of cases which usually occur when a force starts on a march.

MEDICAL CERTIFICATES OF DEATHS FROM VIOLENCE.

At an inquest recently held at Lichfield respecting the death of the Rev. Prebendary Smith, which resulted from a fall downstairs, the deputy coroner is reported to have expressed regret that the medical practitioner who was in attendance during the last illness of the deceased was not "better up in the law" than to give a certificate in the case of a death resulting from an accident. We may be excused for expressing surprise that a deputy coroner should be unaware that under the provisions of the Births and Deaths Registration Act of 1874 a registered medical practitioner is bound to give a certificate, to the best of his knowledge and belief, of the cause of the death of any patient he may have attended during his or her last illness. If, therefore, in the case referred to, the medical certificate duly set out the fall downstairs as the primary cause of death, it is clear that the medical practitioner merely performed his statutory duty under the Registration Act in filling up and issuing the certificate, and the deputy coroner only showed his ignorance of the law in taking exception to such action. It is, however, equally clear that if the certificate gave the accident as the direct or indirect cause of death, the case should have been referred to the coroner previously to the registration of the death, and if the local registrar neglected so to report the death he committed a serious breach of his express regulations on the subject, which should be reported to the Registrar-General. There is no difference of opinion between coroners, the medical profession, and the Registrar-General as to the urgent desirability that all deaths resulting directly or indirectly from violence should be reported to the coroner before registration or burial. The law, however, as it now stands has not provided any satisfactory means by which this desirable course may be secured. It is clear that all such cases cannot automatically come to the knowledge of the

coroner, of his officer, or of the police, and it is equally clear that the coroner must depend upon the medical practitioner and upon the registrar for intimation of a considerable proportion of cases respecting which he has to decide whether it is necessary to hold an inquest. Co-operation between the medical practitioner and the registrar may, moreover, be said to be necessary in order to secure this desirable reference to the coroner. Unless, therefore, the form of violence contributing to the cause of death is set out in the medical certificate the registrar is unable to carry out his instruction to report all such cases to the coroner. On the other hand, in some cases—which should invariably be reported to the Registrar-General—the registrar may neglect his instructions on this subject. Under these circumstances, the medical practitioner will, in certain cases, be justified in hesitating which of two courses he should take with regard to giving a medical certificate relating to a death of which any form of accident or violence has been a contributing cause. If he gives a certificate in which the accident or violence is referred to as a contributing cause, he has fulfilled his statutory and moral duty to the public. If, on the other hand, he wishes to assure himself that the case is reported to the coroner, he will be fully justified in withholding his certificate until he hears that the case has been reported to the coroner, and that he has decided that an inquest is unnecessary, after which the medical practitioner would be bound to give such certificate as the case appears to require. There appears to us to be only one course of action on the part of medical practitioners in the class of cases now under consideration of which coroners would have a right to complain, that is, if a certificate is given which ignores or conceals the fact that any form of accident or violence has been a contributing cause of death. We are free to acknowledge that the wishes of the relatives of a deceased patient to avoid an inquest not infrequently furnish a strong incentive to such a course, which is, however, one that cannot be justified, and which would not only constitute a violation of the spirit, if not of the letter, of the Registration Act, but would reasonably expose the medical practitioner to unfavourable comment by the coroner and by the general public.

EDINBURGH AND LEITH.

At the meeting of the Leith Dean of Guild Court on November 18th the application of the Edinburgh Local Authority for power to erect a temporary hospital for infectious diseases again came up, and was again on most trivial pretence postponed for six days. These repeated delays are becoming a public scandal and a danger to the public health.

THE INDIAN GOVERNMENT AND DR. HAFKINE.

A WELL-INFORMED correspondent writes to us from India that our recent notice regarding M. Pasteur and Dr. Hafkine, published on October 5th, is likely to convey a wrong impression as to the relations of the Government of India in connection with Dr. Hafkine. From July 1st, 1893, to March 31st, 1895, the Government of India allowed him 15 rupees per diem, and first-class travelling allowance for himself and customary allowance for servants and baggage. The residents of Lucknow granted Dr. Hafkine 1,000 rupees, and the Maharajah of Patiala 1,000 rupees. Dr. Hafkine generally lived with medical officers, so that his personal expenses were not considerable. It is not at all intended to imply by this any disparagement of the disinterested and admirable labours of

Dr. Hafkine, but, at the same time, it would not be right to let it be thought that the Government of India did not, to the extent of its ordinary powers, recognise the importance and value of his services.

"MEDICAL AID FREE WITH A POUND OF TEA."

SOME time ago we described the odd scheme of a firm of grocers at Liverpool, who sought to attract and retain customers by promising to supply regular purchasers of their tea with medical treatment free of charge. We are glad to be able to state that we have now received written assurances, which have been published in our columns, from the three medical men whose names were advertised, stating that they have severed their connection with this curious new form of commercial enterprise. The connection in each case seems to have been of short duration, and the scheme—which was certainly calculated to lower the medical profession in the eyes of the public—has thus, through the publicity which we have given to the matter, been nipped in the bud.

A STATUE TO PASTEUR.

It has been decided to honour Pasteur in the district where his first experiments in vaccinating sheep stricken with anthrax were carried out. These experiments were made at Pouilly-le-Fort in 1881, and in grateful memory of the benefits which accrued to agriculture as the result of these scientific experiments a statue is to be erected to Pasteur at Melun, near Fontainebleau. A committee, consisting of members of the agricultural and veterinary societies of the Department of the Seine-et-Marne has been formed for the purpose of receiving subscriptions.

THE LATE DR. THOMAS KEITH.

At the first meeting for the present session of the Glasgow Obstetrical and Gynecological Society a resolution was unanimously adopted expressing sincere regret at the loss which the Society and the profession had sustained by the death of Dr. Thomas Keith, an Honorary Fellow of the Society, and a vote of sympathy with Mrs. Keith and her family was passed. The resolution contained the following passages: "We record our high admiration for him as a man, and as a noble example of what a physician should be. The work he did has placed his name in the forefront of the medical profession, and the fact that much of it was accomplished in great physical pain adds to our admiration for the man whose skill in alleviating the sufferings of others was only equalled by the fortitude with which he bore his own."

INFLUENZA STATIONARY.

THE information which has reached us since the publication of the results of our special inquiry last week is, on the whole, of a reassuring nature. In London the number of deaths attributed to influenza was 11 as compared with 10 in the preceding week, but the deaths referred to diseases of the respiratory organs showed a notable decline, and were 84 below the average. This decline is the most satisfactory evidence we have that influenza is not spreading, at least with any rapidity, in the metropolis, since were it doing so its well-known effect in increasing the death-rate from these diseases would have been felt before now. While we may express the hope that the absence of any rapid extension of the disease is an indication of its early disappearance, we must confess to feeling no very rooted confidence that this is the true interpretation of the facts. The latest returns report 4 deaths in Islington, 2 in Mile End Old Town, and 1 each in Kensington, Westminster, Camberwell, Lee, and Chorlton. The earliest of the recent epidemics in London probably began in much the same way by scattered cases in various metropolitan districts during October and November. Moreover, we

hear of numerous cases which, though not always called influenza, are yet suspiciously like our old enemy, in many parts of the West End. In Bristol, as we gather from a communication obligingly sent to us by Dr. Davies, the medical officer of health, matters are very much the same; cases of undoubted influenza, in which the catarrhal symptoms predominate over the nervous, have been treated in some districts, but there are no indications of extensive prevalence. London is at present the key to the situation, for, as has been mentioned by several medical officers of health to large towns in their recent communications to us, past experience has shown that, once the epidemic really lays hold of London, its extension to the provincial centres of population is only a matter of a short time—on the average about a fortnight.

A MEDICAL EXPLORER.

THE medical profession has yielded several explorers. Their names are enrolled among those who have helped to rescue Central Africa from barbarism. Emin Pasha and Dr. Parke will not soon be forgotten. Among the feats which had hitherto baffled the efforts of the most intrepid travellers was the exploration of Lake Rudolf. Thomson and Gregory both tried to reach the lake from Masailand, but were defeated in their endeavours by the hostility of the native tribes and the dangers of the climate. A young American medical man, Dr. Donaldson Smith, has, however, succeeded in reaching Lake Rudolf from the north through Somaliland. He is thus the first white man who has visited this *terra incognita*, and geographers are looking forward with interest to the publication of his records and diaries. Dr. Smith was in Somaliland on a sporting expedition, and hearing that no white man had ever penetrated to Lake Rudolf from the north he determined to make the attempt. He came to England, and made preparations for this serious and dangerous expedition. He left London last May, and took with him Mr. Gillett, a taxidermist, and Mr. E. Dodson. The former was obliged to return home. It has always been believed that Lake Rudolf lay in the midst of a fertile country, rich in ivory, but peopled by implacable and hostile tribes. We congratulate our medical colleague on being the first to bring light into this dark continent.

SUGGESTED REORGANISATION OF THE INDIAN MEDICAL SERVICE.

AMONGST the mass of correspondence which we have received on the subject of the reorganisation of the medical services recently proposed by Mr. Ernest Hart, the following letter, which comes from an eminent P.M.O., is one of the most succinct. We have a great number of others of similar effect, but this, perhaps, puts the case as shortly and clearly as could be desired: "In acknowledging the receipt of a copy of your address on the Needs of India and in compliance with your circular request for comment, etc., I feel myself bound to say that the thanks of every unprejudiced member of the medical profession in India are due to you for the fearless way in which you have expressed what must be the ideas running in the minds of all. You seem to have grasped the subject in a manner truly astonishing, and you appear to be quite aware of the absurdity of the *raison d'être* for the continued existence of the civil medical department put forward by its late head, namely, that it serves as a reserve for the army in time of trouble. Was ever such a futile protest made to prop up a failing institution? To supply the wants of a single division mobilised in Bengal Indian medical officers had to be called from civil stations and from Madras and Bombay, and the leave of medical officers stopped all over the country. This was for a single division for Chitral. Now, supposing an army corps was mobilised, say, to watch the frontier, all the medical schools and colleges must close their doors, and the gaois and civil stations be left without medical aid, or handed over to the few native hospital assistants who could be spared from military service. In fact, the total dislocation of the

civil medical service, such as it is, of the country must follow if military operations were prolonged. What I wish to insist on is that the present number of men who are told off for military duty is insufficient to supply the wants of native regiments alone, and that the calling out of the so-called reserve—that is, the portion of the military medical service lent for civil duties—for the purposes of field and base hospitals would utterly paralyse the medical service of the country. The remedy you suggest is the only possible one—namely, the creation of a highly paid civil medical service. This might be recruited from the present Indian Medical Service by calling for volunteers, those preferring it being transferred to the medical staff, which would then undertake the military services of the country. To advocate such an upsetting of vested interests and fat sinecures you must be prepared for all the abuse that their holders can heap on your head, but if you persevere you must succeed. The present position is utterly untenable. Medical men who have served a lifetime in civil duties are suddenly pitchforked into principal medical officerships, with the duties of which they are utterly unacquainted, with the result that they depend entirely on their native clerks, whose long service in the district office makes them in ordinary routine matters fairly capable advisers."

THE SICK POOR IN IRISH WORKHOUSES: DONEGAL.

IN commenting on the deplorable condition of the lunatic class in the Donegal Workhouse, our Commissioner quotes the opinion of the Lunacy Commissioners (as expressed in their report of July, 1894) on the treatment of these most unhappy patients throughout the workhouses of Ireland. Unfortunately, it would seem that each Board of Guardians has been content to assume that the general denunciation of sins of omission and commission in this respect applied, as in the case of pulpit condemnations, to their neighbours only, and had no reference to themselves. Our representative, however, brings home the accusation of inhumanity and neglect in this case by a plain statement of facts, almost inconceivable to those who do not know what horrors a bad system, ignorance, and poverty may conjointly produce in the administration of our Poor Law. At Donegal the old cells are in use, two patients being in each cell; two women, semi-idiotic, semi-paralysed, and entirely helpless, lay in box beds on straw, in the dark unventilated cell; the three epileptics who were up had no other resting place than a bench in the corridor, a mere passage giving access to the cells; they were all in charge of a pauper. They looked unwashed and untended, as of course they were, in any true sense of the words. Surely the Lunacy Commissioners have power to enforce their mandates and put an end to this scandalous state of affairs. We hope that some scheme of amalgamating the unions will before long remove the poor idiots from the control of the local guardians to some central asylum where the helpless will be nursed, and all grades of mental disease suitably treated. The present condition of these poor wretches is a disgrace to our boasted civilisation.

"KISSING THE BOOK."

IT appears to be exceedingly difficult to make the minor judges obey the law. Over and over again in these columns we have had occasion to refer to the flagrant illegalities committed by magistrates, coroners, and county court judges in not merely refusing to allow witnesses the right to take the oath in the new form, but in browbeating and bullying those who make that exceedingly reasonable claim. The last incident reported in the daily press is a particularly bad case. It is stated that at the Whitechapel County Court a few days ago a witness, who was himself Scotch, strongly objected to "kiss the Book" on the ground that it had been kissed by hundreds of people that morning, and that some of them had probably been suffering from disease. As our readers

are aware, the witness has an absolute right by statute to take this ground, and he was entitled to take the oath without further discussion according to what was originally the Scottish form, that is, by holding up his right hand without kissing the Book at all. One would have supposed that the county court judge, who was Judge Bacon, would have known this very simple point of law, especially as the late Home Secretary, in consequence of numerous complaints, addressed an official circular to all judicial officers specially calling their attention to the Act. It is reported, however, that what happened at Whitechapel was that the Scotch gentleman was first of all bullied by the usher, who told him "he must kiss the Book," and then reprimanded by the judge, who singularly enough told him he ought to have asked to have the Book opened, and finally compelled him to kiss it in that fashion, although the witness with perfect truth remarked that that "did not make it much better." We should really like to know what excuse is to be made for County Court judges, and even judges of the High Court, who persist in this childish disregard of what is now a well-known matter of elementary practice; and we sincerely hope that some of our readers will absolutely refuse to kiss one of these dirty and infectious Court Testaments, and will tell the judge to his face that he ought to know the Act of Parliament and to obey it.

TENURE OF POOR-LAW APPOINTMENTS IN SCOTLAND.

A CORRESPONDENT signing himself "Rusticus" sends us a striking instance of the high handed and inconsiderate manner in which parish councils in Scotland too often treat their parochial medical officers. He states that he has held the appointment of medical officer to a certain parish for more than a quarter of a century, and has never incurred censure. Recently, without it would seem any warning or reason assigned, he received notice that the parish council had by formal resolution determined that his appointment should end next May, and that advertisements should be issued for a medical officer or officers for the whole or two divisions of the parish before the meeting of the parish council next February. There can be no doubt that the parish council has the legal power, possessed previously by the parochial board, of giving a parochial medical officer in Scotland notice to terminate his appointment without assigning a reason. Parochial medical officers in Scotland, unlike their brethren in England, have no fixity of tenure. We last year pressing suggested that they should organise themselves with a view to securing a remedy for this unfortunate condition of affairs, and offered to render any assistance we could in the matter, but no attempt was made to adopt the suggestion.

THE "DAILY CHRONICLE" AND THE PRISONS.

IN THE BRITISH MEDICAL JOURNAL of November 2nd exception was taken to a statement made in the *Daily Chronicle* to the effect that it was a "solemn finding" of the Prisons Committee that insanity was "produced in prisons by the very low and distasteful dietary to which habitual petty offenders are almost continually subjected." Our contemporary, in replying to our observations, quotes the passage in the report on which reliance is placed. It is to be found on p. 35 in connection with No. diet:

As a considerable number of prisoners are sentenced for a week or less, and after discharge are repeatedly readmitted at short intervals, this very low and distasteful dietary becomes in their case practically compulsory. As it is among such prisoners that cases of mental instability and unsoundness are most commonly found, we feel inclined to endorse the view expressed by the medical officer of Holloway Prison that this part of the dietary should be reconsidered.

The *Daily Chronicle* is illogical enough to twist this into a "solemn finding" that prison diet produces insanity. The petty offenders for the most part chronicle inebriates—who come under this scale of diet, and who are constantly being reconvicted, are not in the nature of things "level headed"

people all round; and we entirely agree with the Committee in their opinion, implied in the recommendation we have quoted, that a continued low diet is not suitable for those who are either mentally or physically weak, and that the risk involved in so treating them should be minimised as far as possible. It must be borne in mind, however, that medical officers have ample powers given them for dealing with all such cases and to order whatever diet they think necessary. A special standing order, No. 142, was in fact issued by the Commissioners in February, 1886, on this subject, and it directs that cases of this class should be brought under the notice of medical officers with a view to an increase of the ordinary diet. The steady and continuous decline which has taken place in the death-rate of the prisons, from 11 per 1,000—at which it stood for several years before 1878, when the local prisons were handed over to the Commissioners—to 7.6 per 1,000—at which it stands at the present time—furnishes conclusive evidence of the way in which the work of the medical department has been conducted. Facts like these are, from a medical point of view, worth bushels of criticism founded on *a priori* theories as to the effects of imprisonment in lowering either the mental or physical health of the ordinary inmates of Her Majesty's prisons.

THE "NAUHEIM TREATMENT" AT BATH.

ARTIFICIAL "Thermalsoolbäder," we are informed, are now in use at Bath. By the addition of carbonic acid gas the "Sprudel bath" at Nauheim can be imitated. The Schott system of exercises can also be employed under medical direction. Thus the whole "Nauheim method" of treatment in cardiac affections has been introduced at Bath, as it has been at Buxton and at Llangammarch Wells in Central Wales. In the case of spas which possess waters of feeble mineralisation such as Bath, it is specially desirable in many cases that the indifferent thermal treatment should be supplemented by the employment of energetic hydrotherapeutic procedures, and this the authorities at Bath have already acknowledged by the introduction of the "douche-massage," as employed at Aix-les-Bains. A writer in a recent issue of the *Bath Chronicle* speaks of "Bath salts" under the influence of the carbonic acid gas being possibly "absorbed into the blood by cutaneous action." Regarding this, we believe that the theory of a therapeutic effect by absorption through the skin of salts from mineral water baths has been given up by most authorities.

ASHANTI EXPEDITION: THE WEAPONS SELECTED.

Tan decision of the War Office to arm the men of the Ashanti expedition specially with the Martini-Henry carbine has been somewhat adversely criticised in certain military circles, and by some seized upon as an indication that the authorities are not quite confident of the power of the Lee-Metford rifle to stop a rush of fanatical natives. We are disposed to think that the War Office has been well advised in this matter, as the circumstances under which the expedition will have to fight—if they have to fight at all—are such that the value of the Lee-Metford rifle would be largely discounted. Much of the district through which the force will have to pass is a thick scrub, having only winding footpaths through it. Presuming the scrub and bush to be held by hostile natives, the opportunities for an aimed fire with weapons of high velocity and low trajectory will be few. On the other hand, the use of weapons loaded with slugs and missiles of that kind is likely to be of the greatest value. For obvious reasons, the War Office is adverse to permitting the Lee-Metford rifle or carbine to be used for ammunition of this nature; while the short barrel of the Martini-Henry carbine, carrying a long bayonet, will be of maternal advantage in the kind of country through which the expedition must operate. Another practical point is this. The expedition is really a mixed force of European and native troops. The latter are still armed with Martini-Henry rifles, and the

issue of carbines of the same type to both classes will remove the need for a supply of two species of ammunition—a circumstance always to be deprecated in military undertakings. Any doubt as to the efficiency of the Lee-Metford rifle or carbine to stop a rush of natives has not, we believe, actuated the War Office at all in their decision; the fact being simply that, under all the circumstances of the case, the Martini-Henry carbine is the more suitable weapon. We note with satisfaction that the non-commissioned officers of the bearer company are to be armed with revolvers and the men with the same carbine as that issued to the men of the rest of the force. Though not constituting an offensive element in the expedition, it is clearly a matter of common sense that the men of the Medical Staff Corps should be armed for defence against attack.

THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

THE Council of the Royal Medical and Chirurgical Society have arranged to hold four special discussions during the course of the present session. They have been encouraged to persevere with this innovation, introduced last session, by the success of the discussion which took place in March last on the Affections of the Nervous System in the Early (Secondary) Stages of Syphilis. It brought out some really valuable contributions to the knowledge of a somewhat obscure subject, as was shown in the reports published in this JOURNAL at the time. The subject of the next discussion, which will commence at the meeting of the Society on Tuesday next, will be the Possibilities as to the Latency of Parasitic Germs in Animal Tissues in Hydrophobia, Erysipelas, Syphilis, Leprosy, Ringworm, Tuberculosis, and other Diseases. The President, Mr. Jonathan Hutchinson, in opening the discussion, will seek to define its scope and aim. The general experimental evidence as to the latency of micro-organisms in the bodies of men and animals will be dealt with by Dr. Washbourn, and Dr. J. Kingston Fowler will discuss the evidence as to the possibility of the virus of tuberculosis remaining latent for long periods. Dr. Phineas Abraham will deal with leprosy from a similar point of view, and Mr. J. Ernest Lane will discuss the latency period of incubation and recurrent activity of the poison of syphilis.

THE PRICE OF POPULAR GOVERNMENT.

It is part of the price paid for popular government that its machinery may be diverted from its legitimate use into a means of stultifying public opinion. It is within the power of a recalcitrant minority, by packing a meeting with members who have a vote but through indifference have not followed the progress of a discussion, to overturn the deliberate resolution of men and women who have devoted time and thought to the solution of a problem. This has happened at Rugby. The Board had been for months considering the question of how to deal with the sick in the workhouse, and had at last decided to build a new infirmary; the plans had been drawn and had received the sanction of the Local Government Board. At the meeting of the Board, held on November 11th, the whole of this business was upset by the reopening of the question and an adverse vote recorded; as we read "that several of the guardians left the room immediately after the amendment had been carried," we conclude that certain members had made use of some wire-pulling. At any rate, it is most unfortunate that the present inconvenient and crowded infirmary is to remain. It has been patched and added to, but grave defects still exist, such as narrow staircases, up or down which it is a matter of extreme difficulty to carry the living or the dead; wards artistically decorated by a philanthropic lady but low-pitched and small, lacking dayrooms and without any of those accessories to nursing which are now considered necessary; sanitary arrangements out of date and inconvenient. We understand that it is now proposed to lengthen the infirmary wards; this means increasing the length of wards already too narrow

without adding to the height, leaving the narrow staircases, which are a source of danger in case of fire, leaving the present quarters for the nurse, which do not admit of extension in the event of the necessary addition to the nursing staff, and not altering the defects in the bath and lavatory offices. When will guardians learn that money spent on patching is the most unsatisfactory of all expenditure, and when will they see that the perpetual referring back of plans to an architect, together with the incidental expenses, is a waste of public money, time and temper?

BACTERIA IN ICE.

THE dangers incident to the consumption of ice obtained from polluted sources, as lakes or ponds receiving sewage, have been much insisted on; and not only have actual instances of the communication of enteric fever in this manner been quoted, but the bacteriological examination of different samples of melted ice have been adduced to show that the process of freezing has no influence on the number or vitality of the microbes. Ice water, for example, from the Spree, has been found to contain 1,700 to the c.c.m., and from the Lake of Geneva 210, while melted hailstones yielded 72. But the recent experiments of Professor Christomanor, of Athens, go some way towards justifying the old and popular belief in the purifying action of congelation, which, as he shows, effects a partial separation of all impurities, concentrating them in the inner portion of the mass. Examining blocks of artificial ice from a factory supplied by a well, and others of water from the aqueduct of Hadrian, he observed in all a central core, forming about a fourth part of the entire volume, and, in its whitish, dull, somewhat granular appearance contrasting strongly with the perfect and colourless transparency of the surrounding ice. While the original water from the aqueduct contained 30 milligrammes of "organic matter" [solids lost in ignition?] in the litre, that from the clear ice showed only 2.8, while the turbid central portion gave 105.5. So with the water from the well, the 64 milligrammes in which were divided in the ice into 5.5 and 202 milligrammes per litre respectively. It is remarkable that, though the one water was charged with organic or presumably organic, impurities, to the extent of more than twice as much as the other, the relative proportions in which these were distributed in the ice were practically identical, being respectively as 9.3 and 351.6, and 8.6 and 311.3 to 100 parts, or roughly, $\frac{1}{4}$ of, and 3 to $3\frac{1}{2}$ times the impurity of the water.

GLASGOW UNIVERSITY MEDICAL DEPARTMENT FOR WOMEN.

THE women medical students of Queen Margaret College, now the women's department of the University, enter this week into possession of their new anatomical and histological laboratories. Queen Margaret College is situated in its own grounds, adjoining the Botanic Gardens, at a short distance from the University. The new anatomical building has been erected apart from the major college building, but within the grounds. It consists of a dissecting room, 48 feet by 28, lighted from the roof. A dado of white tiles runs in the walls, and above it a black board all round the room. Above the black board the wall is of adamant plaster. The room is provided with every convenience in the shape of wash basins, sinks, lifts, etc. There is a museum 33 feet long, 24 broad, and 38 high, provided with a gallery. The theatre is 25 feet square, the seats rising rapidly and in a semicircular fashion from the well, the windows being so arranged that the light is focussed on to the lecturer's table, and the board and wall behind. The theatre is seated for 100. Upstairs is a room 20 feet square, arranged for the meetings of the histology class. Besides these is a private laboratory for the lecturer, fitted with every convenience for microscopical work, a similar apartment upstairs for private students, cloak room, lavatory accommodation, etc., for the students, opening from the entrance hall, and in the bast-

ment workshop and preparation rooms, furnace room, and rooms for the heating apparatus. The whole building was designed somewhat after the Oxford model, and is characterised by the simplicity, but rarity, and artistic quality of the detail. The cost of the building has been defrayed by the Bellaboustone Trust, who have been satisfied that the progress of the medical school justified the expenditure. And the justification seems ample, for it was only in 1889 that this medical department for women was organised. In that year the students numbered 13. Now, at the beginning of the sixth year, the attendance is 67, while the total number of students in the college is 232. Of the ladies who have graduated in medicine and surgery, 2 are in practice in Glasgow, 5 are engaged in foreign mission work in India, 1 is in Egypt, and 2 are ready to proceed to China.

MEDICAL WOMEN AND THE LONDON COLLEGES.

THE resolution adopted by the Council of the Royal College of Surgeons at its last meeting marks a distinct stage in the agitation in favour of the admission of women to the examinations of the Royal Colleges of Physicians and Surgeons in London—that is to say to the Conjoint Board in England. The Council of the College of Surgeons has now formally declared that it is in favour of granting the petition of the officers and teachers of the London School of Medicine for Women for the admission of women to these examinations. The Council, however, has not seen its way to give effect to this opinion in view of the opinion expressed by the College of Physicians, and adverse vote of the meeting of the Fellows and Members of the Royal College of Surgeons adopted at the annual meeting on November 7th.¹ The majority then was 10 in a meeting of over 100, and the majority at the College of Physicians was, it may be remembered, much the same. We may therefore anticipate that a solution of this difficulty in a sense favourable to the demands of women will be reached before many years are past, and that not improbably the general revision of the arrangements for medical examinations in London which must attend the creation of a teaching university for London will afford an occasion for recognising their claims.

DEGREES FOR LONDON MEDICAL STUDENTS.

THE report of the important meeting of the teachers of the London medical schools, held on November 20th, which will be found in another column, will be read with much interest. The meeting was unanimous in resolving to ask the Government to introduce a Bill similar to that brought before the House of Lords by Lord Playfair last May, but with an added clause giving power to institutions or persons affected by any proposal made by the Statutory Commission to appeal to the Privy Council. Backed up by this unanimous expression of opinion, the deputation which it is proposed to send to the Lord President of the Council is assured of a favourable hearing. The Bill proposed to appoint a Statutory Commission to carry out the necessary adjustments to ensure that justice should be done to all interests, and it is confidently expected that with the reservation of an appeal to the Privy Council much of the opposition threatened last year will lose its force, and that the Duke of Devonshire will see his way to induce the Government to give facilities for the passage of the Bill at an early date.

THE RETIREMENT OF MR. LAKEMAN.

WE have to announce the retirement of Mr. J. B. Lakeman, Her Majesty's Superintending Inspector of Factories and Workshops, with much regret, on account of the very active and useful life of nearly half a century spent in the service of the State. In 1881-2 Mr. Lakeman undertook the arduous work of visiting the London retail bakeries, in which gross evils were found, and his reports on them were

largely printed in the press. The upshot of the agitation was the passing of a new Act in 1883, giving the sanitative condition of all retail bakeries over to medical officers of health, whilst the other portions of the Act remained in the hands of Her Majesty's Inspectors. One of the gravest tasks undertaken by him was an endeavour to grapple with the growing evil of the sweating system in the clothing and boot and shoe trades. He gave evidence before several Commissions, notably the Sweating Committee, wherein he laid all his experiences of the various aspects of these trades before its members upon the insanitation, overwork and deprivation of time for meals, and the hardships inflicted upon the females employed in them, his statistical report of 1887 being an exposure of the sad evils appertaining to these trades. He contributed articles to the *Sanitary Record* in which the history of the sweating system was plainly stated. He then took charge under the Act of 1891 of all the workshops in London as the administrator of the law and director of a staff of officers appointed to serve under him. Mr. Lakeman's retirement will be a loss to the public.

THE PROPOSED NEW HOSPITAL NEAR DUBLIN.

AT a conjoint meeting of the Sections of Medicine and State Medicine of the Royal Academy of Medicine in Ireland, held on Friday, November 15th, the subject of the proposed hospital for infectious diseases was under consideration. Dr. Grimshaw, President of the Royal College of Physicians, presided. Dr. J. W. Moore read a paper entirely hostile to the proposal, and Sir Charles Cameron, superintendent officer of health, followed in support of the scheme. A long discussion followed, in which the President of the Academy, Dr. James Little; Sir Thornley Stoker, President of the Royal College of Surgeons; Dr. W. G. Smith, Dr. C. F. Moore, Mr. Thomson, Vice-President of the Royal College of Surgeons; Mr. Tobin, Dr. Parsons, Dr. Craig, Dr. Falkiner, and other took part. The speakers strongly opposed the erection of the hospital for general infectious diseases, but they were generally in favour of a hospital for epidemic small-pox or cholera, and of convalescent homes. Sir C. Cameron, in his reply, said he would advise the abandonment of the larger scheme, and would only proceed with the suggestions that had received approval from the meeting.

INFECTED CABS.

A RATHER curious case, illustrating the divided responsibility which exists as to the measures necessary for the prevention of the spread of infection, came before Mr. Sheil at the Westminster Police-court on November 18th. It appears that on November 9th Dr. J. J. Marsh, Honorary Physician to the Chelsea, Brompton, and Belgrave Dispensary, saw a case of diphtheria in a child at the dispensary house in Sloane Square. He told the mother to take the child home, and, on her way, to leave the notification certificate at the Chelsea Town Hall. At her request he allowed the dispensary porter to call her a cab. At the town hall the sanitary inspector took the number of the cab, and told the cabman to drive the patient and mother home, and return. On doing so the cabman was told that the child was suffering from diphtheria, and that his cab must be disinfected. Owing to the time this process took he incurred a loss which he estimated at £1. The sanitary authority refused to compensate him, and he sued Dr. Marsh. The magistrate said that he was satisfied that Dr. Marsh was not liable. Having obtained a decision on that question of principle, Dr. Marsh offered to compensate the cabman, but Mr. Sheil intervened, and said that he would cause inquiries to be made, as the case might be one for the Court to relieve. Everyone will feel that it is a hard case for the cabman, and will not withhold from Dr. Marsh his meed of sympathy. At the same time it seems hardly right that the cabman should be compensated out of funds subscribed for charitable purposes. In equity, if not in law, the charge ought to fall upon the sanitary rate. Similar difficulties, which used to be of somewhat common

¹ BRITISH MEDICAL JOURNAL, November 29th, p. 1170.

occurrence, have been met to a large extent by an arrangement between the Metropolitan Asylums Board and most of the institutions which treat out-patients in London. Under this the Board undertakes, on receipt of a message by telegraph or telephone, to send an ambulance to remove a patient suffering from any of the infectious diseases treated in its hospitals. By this shortening of procedure not only is a great deal of time saved, but all these troublesome questions which must arise when the infected person is taken home by friends are avoided. The advantage to the patient, also, is obvious, and the general extension of this plan to all the public medical institutions treating out-patients is much to be desired.

SHEFFIELD AND THE VICTORIA UNIVERSITY.

An effort is being made to obtain the admission of Firth College, Sheffield, as a college of the Victoria University. An application was laid before the Court of the University on November 14th, and from the favourable manner in which the application was received there is little question that, provided the needful requirements can be complied with, Sheffield will soon enjoy the advantages of a University college. Associated with Firth College in their application are the Medical School and the Technical School, and it is suggested that the three institutions should be merged into one under the name of the Sheffield University College. The application for incorporation with the Victoria University was referred to the Council of the University for consideration, and afterwards it will again come before the Court to decide as to the admission of Firth College. There has been for some time great activity in the work of Firth College, and under the able guidance of the Principal, Professor Hicks, F.R.S., its usefulness and reputation have been greatly enhanced. The Medical School, established as long ago as 1828, has been keeping itself well abreast of the times, and particularly in the anatomical and physiological departments is the increased energy conspicuous. The Technical School is also doing good work in an essentially industrial centre. Events, therefore, have been making for the step which is now contemplated.

CLOTHES AND COLD-CATCHING.

Dr. CLEVELAND, in a paper read at a recent meeting of the North London District of the Metropolitan Counties Branch, gave some interesting hints as to the cold-catching and its avoidance. After referring to the damage which may be caused to internal organs—weak, perhaps, owing to previous disease or a delicate constitution by the congestion due to the action of cold on the surface—he went on to refer to the theory propounded many years ago by Sir Henry Holland in the following words: "It is . . . a question here whether variations of atmospheric temperature may not induce a state of body rendering it more liable to receive specific infections however generated by agents without." This view, as Sir William Priestley, who presided at the meeting, observed, has found support in the observations of Pasteur on the effect of lowering their temperature in rendering fowls liable to contract anthrax. The hypothesis, Dr. Cleveland went on to point out, suggests the desirability of specially protecting the body by warm clothing, exercise short of fatigue, and a diet perhaps more generous than usual during an epidemic of influenza such as that which appears now to be threatening London. He pointed to the great difference between the warmth of day and evening garments as worn, not only by women but by men, as a source of danger; and, in the case of the sterner sex, to the peculiar perversity of the tailor, who will make a waistcoat with a front of woollen stuff or even of fur, and a back of cotton material. Another piece of practical wisdom in the paper was a strong condemnation of the false pride which causes old and delicate people to go to bed with cold feet, and remain awake in consequence half the night, rather than confess to the comfort of a hot-water bottle.

THE HUXLEY MEMORIAL.

The first meeting of the General Committee of the Huxley Memorial will be held on Wednesday, November 27th, at 4 P.M., in the Museum of Practical Geology, Jermyn Street, his Grace the Duke of Devonshire, Lord President of the Council, in the chair. Resolutions with respect to the form of the memorial will be submitted to the meeting.

THE REGIUS PROFESSORSHIP OF SURGERY AT DUBLIN.

As we announced last week, the Board of Trinity College, Dublin, met on Saturday, 16th November, and proceeded to consider the nomination by the Academic Council of Dr. Ball to the office of Regius Professor of Surgery, in succession to the late Sir George Porter. At the previous meeting four voted for the vetoing of the nomination and four in support of it; but on Saturday last the voting was five to three in support of the nomination, one of the members having changed sides. Dr. Ball was therefore formally appointed to the office.

DIPHTHERIA IN LONDON.

ALTHOUGH the mortality from diphtheria showed a slight decline in London last week, the number of deaths attributed to this disease continues to be excessively high. The fatal cases, which had been 61, 72, and 75 in the three preceding weeks, declined again to 61 during the week ending Saturday last, November 16th. During the past five weeks the deaths from diphtheria in the metropolis have averaged 60, a higher number than in any similar period since the end of 1893. The 61 deaths last week were all of young persons under 20 years of age, and included 44 of children under 5 years of age, and 17 of young persons aged between 5 and 20 years. After distributing the fatal cases that occurred in the Metropolitan Asylums Hospitals and other public institutions to the sanitary areas in which the patients had previously resided, it appears that 4 cases belonged to Kensington, 3 to Chelsea, 7 to St. Pancras, 7 to Mile End Old Town, 7 to Camberwell, and 4 to Greenwich. There were 678 diphtheria patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last, and 104 new cases were admitted during the week.

INFECTIOUS "PNEUMONIA."

In reporting on an epidemic of diphtheria at Flint Dr. Reece, one of the medical inspectors of the Local Government Board, makes mention of an interesting outbreak of a pneumonic character, to which his attention had been directed. The disease made its appearance in the town while the population was suffering severely from privation and want, and while the town was undergoing a visitation of influenza. All the signs of typical pneumonia were present in the cases, the temperature rapidly rising to and remaining at 104° or 105° F. When death took place it occurred generally in the first four days of illness. The first three cases all occurred in one house. A young man, his mother (who nursed him), and an old man were attacked at short intervals of time, and all died. There were in all some 35 attacks heard of, and as many as 20 deaths recorded as due to pneumonia from January to July 9th last. They were widely scattered for the most part, having little or no relation with each other, though certain of them occurred within a small radius, and in families, giving reason to suppose that the malady had infective properties. Local opinion was opposed to the idea of its being typhus fever. Several deaths were put down to pneumonia as a sequela to influenza. Omitting cases of a doubtful nature, the ages of the fatal attacks averaged 41 years, and of the non-fatal cases about 34 years. One medical man, who was practising during the typhus epidemic in Flint in 1887, declared that the clinical features of the "pneumonia" were unlike those of typhus fever.

DEGREES FOR LONDON MEDICAL STUDENTS.

MEETING OF LONDON TEACHERS.

A GENERAL meeting of the teachers in the medical schools of London was held at Examination Hall, Victoria Embankment, on Wednesday afternoon, to consider a resolution pressing the Government to appoint a Statutory Commission to deal with the recommendations of the Gresham University Commissioners. The hall was well filled. Dr. FREDERICK TAYLOR presided over the meeting.

In his introductory remarks, the CHAIRMAN said that the meeting was called with the object of furthering the establishment of a university, by modifying the constitution of the existing London University—such as would meet the requirements of those who demand for teachers a prominent share in the management of the University, and of those, like themselves, teachers in the London medical schools, who were anxious that the medical student in London should have easier access to a medical degree than he had at present. The history of the exertions made in that direction went back at least eleven years, when, in 1884, the Association for Promoting a Teaching University in London was formed. No action was taken, however, until about three years later, when, in 1887, the two Royal Colleges, the Royal College of Physicians and the Royal College of Surgeons, petitioned Her Majesty in Council that they might have the power of granting degrees in medicine and surgery, and drafted a charter with that object. The teachers in the medical schools had supported that object by presenting to the Royal Colleges a document, signed by over 200 teachers, to the effect that they "earnestly hoped that the Royal Colleges will use their best endeavours to obtain the powers of granting a degree in medicine. If this power be obtained, it will offer to students of the metropolitan schools an advantage already possessed by students of most of the educational colleges in the country." Simultaneously with that move on the part of the Royal Colleges, the Association for Promoting a Teaching University in London petitioned for a charter enabling them or others to found such a university. At the same time, University and King's Colleges presented a scheme for an Albert University, founded very much on the lines of the Association. The result of the petitions was the appointment of a Commission to make a full inquiry into the whole subject. In their report issued to Parliament on May 30th, 1889, the Commissioners expressed their opinion that the case for a teaching university was made out, and that the demand for a medical degree on the part of the London student was a just one. They did not support the plea of the Royal Colleges for power to grant a degree, but recommended that a reasonable time should be allowed to the Senate and Convocation of the University of London to consider whether they would apply for a new charter to attain the end desired. Should they do that the Commissioners would recommend that the request of University and King's Colleges should not be granted. The University of London made various attempts to modify its constitution in order to meet the case, but failed to carry out the recommendation of the Royal Commission; and the promoters of the Albert University maintained that their scheme held the field. But there was opposition in other quarters, namely, the provinces, and coming forward at a time when the Government of the day was in its last year of office, the draft charter of the Albert University, under the name of the Gresham University Scheme, was referred to another Royal Commission in April, 1892. That Commission was presided over by Lord Cowper, and was larger and more representative than the former. A large number of sittings was held during the summer and autumn of 1892, and the Commissioners' report was issued in January, 1894, recommending: (1) That there should be only one university in London; (2) that the existing University should be reconstructed to meet the desired object; and (3) that the changes recommended should be effected, not by charter, but by the appointment of a Commission with statutory powers to settle arrangements in accordance with the Commissioners' recommendations. The first recommendation implied the principle that the functions of examining and teaching could be adequately fulfilled by one university, and from that

principle only two out of the thirteen Commissioners dissented. As yet, however, no such Commission with statutory powers had been appointed. In the meanwhile the position of the London University had undergone a change. At the meeting of the Convocation in January, 1894, a resolution was agreed to, arranging for a consultative meeting of the Senate and Convocation with reference to the course it should adopt. At the meeting in May Convocation nominated an Annual Committee, consisting almost entirely of members favourable to the modification of the London University in the way desired. In January last a motion to the effect that one university alone was desirable in London was carried by 206 to 175; and in May a motion to rescind that and accompanying resolutions was rejected by 240 to 119, or 2 to 1. In the meanwhile steps were being taken by other bodies interested in the proposed new University; and on January 22nd, 1895, the then Prime Minister, Lord Rosebery, received a deputation consisting of delegates from those various bodies, and on hearing, later in the same day, the case for the opposition presented by themselves, stated that the convictions of the Government rather pointed in the direction of the appointment of a Statutory Commission for framing such a scheme. On May 9th a Bill was introduced in the House of Lords by Lord Playfair for the Government, intitled, "An Act to make further provision with respect to the University of London." That Act arranged for the appointment of Commissioners "to make statutes or ordinances for the University of London in general accordance with the scheme of the report..... but subject to any modifications which may appear to them expedient after considering any representations made to them by the Senate or Convocation of the University of London, or by any other body or persons affected." It was further provided, that all such statutes or ordinances should be laid forthwith before both Houses, to come into effect forty days after being so laid before Parliament. He (Dr. Taylor) had now, he thought, brought the history of the movement to the point at which he might hand over to the mover the resolution. It was within the memory of all that in the end of June Lord Rosebery's Government resigned, and Lord Playfair's Bill never became law. What was before them now was to urge the present Government to take steps similar to those which the late Government had already initiated. Finally, he wished to impress upon those present at the meeting, first, that that meeting of the teachers in the London medical schools had been arranged for by the delegates representing those medical schools for the purpose of promoting the formation of a teaching university by suitable modifications in the existing University of London, so that one university should be all that was required; secondly, that that university should be constituted by a Statutory Commission; and, thirdly, that there should be a right of appeal to the Privy Council previous to the statutes and ordinances being approved by Parliament.

Dr. NORMAN MOORE then moved:

That the Government be requested to introduce at an early date a Bill similar to Lord Playfair's London University Commission Bill, 1893, appointing a Statutory Commission to carry out the recommendations of Lord Cowper's Commission; but with an added clause giving (in accordance with precedent Acts of similar tenour) to all institutions or persons directly affected by any Statute or Ordinance proposed by the Statutory Commission a right of appeal to the Privy Council for the disallowance or alteration thereof, previous to such Ordinance being laid before Parliament for confirmation.

He said that having attended meetings upon the matter since the spring of 1884 he could confirm from personal knowledge all the details which the Chairman had given except some of those referring to what had taken place within the walls of the University of London. First of all he would speak of the difference in the wording of the resolution on the card of invitation sent out and that on the printed form, as he had moved it, the words "deal with" being inserted in the one and "carry out" in the other. The wish to change these seemed to be based upon some want of consideration of the nature of a Statutory Commission. Most things which had to be settled by Parliament came before Parliament in all their details. A Statutory Commission was an exception to the rule; it proposed to deal with people's prospects and with their property without laying down the precise ways in which

their prospects or their property should be dealt with. It seemed, therefore, that when a Statutory Commission of that kind was formed, it was highly important that there should be some limits to its powers in dealing with the subject. Therefore he was strongly in favour of that form of resolution which he had moved which would enable the Statutory Commission to carry out the principles of the report of Lord Cowper's Commission, but would not allow that Commission completely to metamorphose the report, and give them something of which they had not yet heard. He supposed that everyone was acquainted with the details of the report of that Commission, and the very simple question before them was, Were they content with it? They had been endeavouring to do something in that way for eleven years; was the point which the subject had reached one that was satisfactory to them? If it were they must go on; if it were not they ought to declare that it was unsatisfactory, and that something else should be done. On former occasions it had been frequently said that what they wanted was some way of giving a cheap and easily-obtained degree. Such a suggestion could only have been made by someone who lived within a little narrow circle, some town or association where people kept before them the getting of a degree as the sole end of university life. Such an idea could never have come into the head of any one who was acquainted with two things—first of all with the teachers of London assembled at that place, and secondly with even the elements of University education. The object of a man in going to a university was not merely to get a degree, although of course he was unwilling to leave the university without obtaining one. But his object in going there was to get the highest kind of education in one particular direction, and the degree was merely a piece of evidence that that object had been attained. Out of certainly 300 meetings or more which he had attended he had never been present at one in which an impartial observer would have said that their general aim and wish was merely to obtain an easily earned degree for their students. In other places teachers had great powers of managing their own universities—it was so in the Universities of Oxford and Cambridge, and nearly all those in Germany; in other words, the direction of the higher kind of education was in the hands of those people who gave the education, and not of some outside person. They felt that the teachers of London—he was speaking only of medicine, but no doubt it was the same in other subjects—had scarcely any influence in arranging the curriculum, and in deciding what was best for the students to know. It had been said that if the teachers had that power they would use it meanly in order to increase their incomes by inducing students to come to London. Was that a fact? Was that a just accusation to bring against any body of learned persons engaged in promoting the study of the vast series of subjects which were included under the subject of medicine? He maintained that it was not. Would the report of the Commission if carried out give them what they wanted? They wanted a sound university, one which would bring all the teachers, and no doubt to some extent all the students, together, and would provide that stimulus to work which everybody who had ever lived in a university knew was obtained in that way. Let them look back on their own university career and see what they had gained by it. It was an advantage to attend the lectures of celebrated people, and not a less advantage—in some cases even more advantageous—to associate with fellow students who were anxious to do all they could in their subject and with people who were learned in it, although they were not actually one's own immediate teachers at that time. Would the report produce that kind of university? In other words, would it give them the honourable advantage which they sought, and which they thought they had a right to claim? The governing bodies of the university as proposed in the report were the Senate, the Academic Council, the Faculties, the Boards of Studies, and the Convocation. Now, the Senate consisted of 66 members—about one-sixth of those would necessarily be people acquainted with teaching medicine. The Senate was the highest authority of the University; it was the court of ultimate appeal, the supreme governing body of the University, the representative of the University, in all its corporate relations. The Academic Council,

according to the report, consisted of fifteen members, and a fifth at least of those would be teachers of medicine. That Council was the body which would arrange the curriculum—all courses of studies—and would lay down regulations for examinations. Remembering how small a body it was he thought they might say that medicine, though not in any way over-represented, had a representation which would enable its voice to be heard in all its own affairs. One must take bodies like that by the working of similar bodies in other places, such as the Council and Senate of the University of Cambridge. In such bodies it was not found that the professor of divinity was anxious that anatomy should be left out of the examinations. Therefore in such a council, so long as they were represented by competent men, it was their voices, which would have weight, and not mere voting power. Then the Faculty of Medicine was being represented there by an experiment. That was the Faculty of Medicine—they were the people who would be concerned in all the proceedings of the Faculty of Medicine. They would elect the very members of whom he had been speaking on to the Academic Council; they would appoint the Boards of Studies, three-fourths of them, and in many cases the whole; that was to say, it was highly probable that where an efficient Board of Studies was constituted by that three-quarters, there would be no further addition to it. They would also have the power of discussing and representing to the Academic Councils any views upon teaching and examination, and all the subjects relating to their Faculty. The Board of Studies was a body which met frequently, and gave advice to the Academic Council on all sorts of points which arose. The Boards of Studies would be very much like what were known as the Boards of Studies of the University of Cambridge, where sometimes very important points were discussed, and were afterwards represented to the Council. Finally there was the Convocation. Convocation was essential in all universities—some general assembly to bring the university all together at some time or other. That Convocation would have the power of electing the Chancellor and certain members who would represent it upon the Senate, the supreme governing body of the University. Would that increase the advantages to the students of education in London? He believed that it would, and they ought to ask to have the Statutory Commission appointed and have the matter settled. It was provided that there should be an appeal to the Privy Council. That was to avoid the possibility of injustice being done by so powerful a body as the Statutory Commission, and he strongly approved of it. He would say nothing about the objections to the scheme, because there was no end to answering such objections, nor to the misconstructions which were put forward. One of the most prominent men in this country had actually fought a duel on account of the results supposed to be likely to follow from the foundation of King's College. He gave that as an example of the extravagance to which objections might go. The sympathies of every town in which there was a university—Manchester, Liverpool, Leeds—all the Scotch universities and Oxford and Cambridge, ought to be with them in trying to found that university; and he thought they ought strongly to resolve to obtain the appointment of the Commission mentioned in the resolution.

Mr. FREDERICK TREVES, in seconding the resolution, said that by no means an unreasonable question was, What was the origin of the movement, under what mysterious pressure had the agitation been moving? The motive was no other than that which had revolutionised education within the last fifty years in this country—no other than the expression of that very movement which had insisted upon the removal of all tests, all restrictions, and all limitations in education of all kinds, which had made it essential that all the advantages of education should be thrown open to the greatest possible number, and that should be done with limitation of no kind. The discussion had been very much hampered by the introduction of the average man. They wanted a degree for the average man; and the average man, although he had been been spoken of with a certain amount of contempt, was a person of some considerable importance—certainly numerically of the very greatest importance. The answer was

that if a student in London wished to take a medical degree there was the University of London, but the University of London was hardly fitted for the average man. The work done by that University could not be spoken of too highly; its degrees were great distinctions and amongst its ranks were some of the most distinguished men in the medical profession, but he did not think it could be said that it had a degree for the average man. The answer to that was: "We are not concerned with the average man; our wish is to develop the very highest flights of education; we are concerned, not with the average man, but with the distinguished and exceptional man." He believed that was one of the most fatal arguments, because the greatness of any university depended upon the fact that it appealed to the average man. There was no university in this country or the Continent of which it could not be said that its greatness depended upon the wideness of its application and the fact that it appealed to an enormous number, and not simply that it appealed to a few, and the London University would occupy a very much greater position if it appealed to the somewhat abused average man. As a matter of fact the average man met with little encouragement in London. The London University degree must be regarded as an onerous one. The argument that the proposed university was intended to undersell existing universities was a despicable one. It was said that there was a certain amount of jealousy of the success of provincial universities in Scotland. Those who were concerned in the present movement could not say too much in praise of the provincial universities, but they were naturally distressed that their students should actually remove from London. It did seem a deplorable thing that every year a large number of men were induced to cease to be educated in London for no other reason than that they were not provided with such facilities as they required. They wished to do what they could to provide for the necessities of their own men, and not be met with the sorry sight of students by hundreds leaving London to seek that which they could not obtain there. If the scheme were carried out the University would weld together all the multitudinous interests concerned in the medical education of London; all the little difficulties between this school and that would be lost in the one great scheme.

Dr. ISAMBARD OWEN supported the resolution. He said he could not help expressing regret that the words "to carry out" should have been retained, and the words "to deal with" should not have been restored to the text of the resolution. He and those who thought with him regarded the scheme of the Gresham Commissioners as offering a fair opportunity for a settlement of the University of London question upon a satisfactory basis; but they did not regard that scheme as altogether free from flaws, and in particular they were of opinion that there were certain details which, if carried out precisely as the Gresham Commissioners had laid down, would be disastrous to the interests of medical education. Their desire was that the Statutory Commission appointed by the Government should be appointed not merely to carry out the scheme, but should also have power to take fresh evidence upon that scheme, and to revise such portions of it as they should think necessary.

Professor WILLIAM RAMSAY, F.R.S., pointed out that the phrase "appointing a Statutory Commission" was similar to Lord Playfair's London University Commission Bill. He thought everybody agreed with the views Dr. Owen had expressed, and would not wish to see certain modifications inserted.

Dr. P. H. PYE SMITH, F.R.S., also agreed with Dr. Owen. He thought it was most important that the resolution should be unanimously supported. The present scheme had several points in it which might be amended, but that was not the question before them, and they were not so foolish as to think that in that assembly they could amend an elaborate scheme of that sort. The question before them was whether the scheme of the Royal Commission was on the whole a good one—whether they would rather have that than nothing at all.

Professor CUNOW (of King's College) also supported the resolution.

Dr. A. D. WALLER said it seemed to him that they must all be unanimous in the desire for a university, but what particular kind of university they were to have would lie, no doubt, with the Statutory Commission. He greatly desired to see the reintroduction of Lord Playfair's Bill, with the addition of the guarding clause.

The CHAIRMAN then put the resolution to the meeting, and it was carried unanimously, amidst cheering.

Dr. J. F. PAYNE then moved:

That all teachers be asked to sign the preceding resolution, as "approved" or "not approved;" and that the Chairman be requested to forward a copy of the resolution, with the signatures obtained, to the Lord President of the Council, and other copies of the resolution to the Prime Minister and the President of the Council of Education.

This was seconded by Mr. PICKERING PICK, and unanimously adopted.

On the motion of Dr. MITCHELL BRUCE, seconded by Mr. BLAND SUTTON, the following resolution was assented to:

That the appointed delegates of the Medical Schools of London be requested to attend, with the representatives of other institutions concerned, a deputation to the Lord President of the Council, and to convey to him the wishes of this meeting as expressed in the first resolution.

A vote of thanks to the Committee of Management of the Conjoint Board for England for permitting the use of the theatre for holding the meeting was then passed, and the proceedings closed with a vote of thanks to the Chairman.

LEGISLATION FOR HABITUAL DRUNKARDS.

DEPUTATION TO THE HOME SECRETARY.

SIR MATTHEW WHITE RIDLEY, Home Secretary, on Friday, November 15th, received a deputation from the above-mentioned subject, consisting of Cardinal Vaughan, the Rev. Canon Duckworth (representing the Homes for Inebriates Association), Dr. Norman Kerr (Society for the Study of Inebriety), Sir W. Charley, Q.C., Dr. Danford Thomas (coroner), Mr. F. Fowke (British Medical Association), and Mr. C. J. Maddison (Reformatory and Refuge Union). The Duke of Westminster, Sir Richard Quain (President of the General Medical Council), Sir William Broadbent, Dr. Long Fox (ex-President of the British Medical Association), also Messrs. Lees Knowles, M.P., W. Johnston, M.P., and Edmund Boulnois, M.P., wrote regretting their unavoidable absence and approving of the objects of the deputation.

Dr. NORMAN KERR said that habitual drunkards, with the increasing proportion of diseased inebriates, especially females, constituted a menace to public order. Regarding police-court inebriate offenders, it was now generally agreed that the existing procedure was a miserable failure, and neither deterred nor reformed. There was a physical as well as a moral aspect of inebriety, and curative treatment had been recommended by six State reports. As to non-criminal habitual drunkards, the existing Acts of Parliament required amendment in the direction of facilitating the entrance of patients into homes for inebriates by rendering a declaration before one justice or a statutory commission sufficient instead of the declaration having to be made before two justices. Persons addicted to any narcotic, such as opium, morphine, chloral, or cocaine, should be included in the definition of habitual drunkard. There were few homes for poor inebriate women, and none at all for poor inebriate men. Provision ought to be made for habitual inebriates who could not afford to pay. It would not be a new departure in English jurisprudence to subject to compulsory seclusion inebriates who had not broken the law, as the existing system provided for the compulsory treatment of insanity, of which disease inebriety was practically a form. An effective measure would be incomplete unless it gave power for the curative detention of non-criminal habitual drunkards in retreats, and provision could be made guarding against any possible abuse of such power by the interposition of a judicial authority.

Cardinal VAUGHAN agreed that further power was required to commit habitual drunkards to homes, treatment in which had effected some 8 or 9 per cent. of cures.

The Rev. Canon DUCKWORTH remarked that the legislation proposed by Dr. Kerr would not be in advance of public opinion, and that those for whom he spoke were as zealous

as anyone for the liberty of the subject, but failed to see why the liberty of the inveterate sot should be more respected than the welfare of his family and himself.

Sir W. CHAMLEY, Q.C., suggested the restoration of the compulsory clauses of the Bill of 1877. The percentage of curers affected in homes was more like 30 than the 8 or 9 that had been mentioned. Where was the "liberty of the subject" in such a case as that of Jane Cakebread, who had been committed nearly 300 times? Magistrates ought to have the option of sending such cases to homes instead of the prisons.

Dr. DASFOED THOMAS said he was there to plead on behalf of the poor for the suggested amendments. During his twenty years' experience as coroner, he had daily held an inquiry into death due directly or indirectly to drunkenness. It was no more interference with liberty to send inebriates to be treated in homes than to send cases of infectious disease to hospitals, and the money that the public now had to pay for drunkards in prisons, workhouses, etc., would meet the expense of their curative treatment.

Mr. C. J. MADDESON concurred, remarking that when industrial schools were proposed objection had been raised on the ground of expense, but experience had proved that what they cost the country in one way was saved in another, and that would also be the result of providing the proposed homes for inebriates.

The HOME SECRETARY replied that it did not require such an influential deputation to convince him of the importance of the question. The difficulty of dealing with the non-criminal habitual drunkard was very great, but he could not ignore the reports of the committees to which reference had been made, and it would be of the greatest importance if he could strengthen the homes while at the same time guarding the liberty of the subject. To cure the criminal inebriates (some 6,000 females of that class were at present imprisoned) would be a saving to the country. Something ought to be done, and parts of the Bill of his predecessor in office might serve as a basis for tentative legislation.

Dr. NORMAN KERR, having expressed the thanks of the deputation, the proceedings terminated.

REMUNERATION OF MEDICAL WITNESSES.

IN last week's issue a letter appeared in our columns from Messrs. Lowndes, of Liverpool, and Hopkins, of Bath, joint Secretaries of the Police Surgeons Association, asking police surgeons to become members. The objects of the Association may be briefly stated: To protect the interests of police surgeons generally: to endeavour to get an increased scale of fees granted for giving evidence in courts of law as well as coroners' courts. With these objects in view the Association early in the year waited upon the Home Secretary and pointed out to him how inadequately medical men were remunerated for their service as witnesses, especially if residing any distance from the assize town, the present "liberal" pay being £1 1s. a day, second-class fare, 2s. 6d. a night, and in some districts not even that. Further, medical witnesses receive nothing extra if called upon to give expert evidence in more than one case during the day, which frequently happens—in fact, only this week one of the secretaries had to give evidence in 4 or 5 cases the same day, and, of course, only received the usual £1 1s. The Association, therefore, particularly wish to point out that this question does not affect them alone, but every qualified practitioner in the kingdom, as being liable at any time to be called upon to give evidence, whether he is living in the assize town or not. The remedy suggested by the Home Secretary was that police surgeons should apply for extra remuneration from those bodies who appointed them. Supposing such applications were favourably received, which is more than doubtful, it would not affect those witnesses who are not police surgeons, and of these, of course, there are a very large number.

Letters have occasionally appeared in our columns upon the above subject complaining of the scale of fees allowed, which were formulated about forty years ago. The subject has also been brought under the notice of the Parliamentary Bills Committee of the Association. We therefore think the Association worthy of support, especially as it affects the whole body of practitioners.

We understand that another deputation will wait upon the

Home Secretary in the early spring. The President of the Association, Sir H. D. Littlejohn, has warmly taken the matter up, and with his valuable assistance it is hoped that a reconsideration of the scale of fees may be obtained.

THE MEDICAL PRELIMINARY EXAMINATION AT THE SCOTTISH UNIVERSITIES.

THE Joint Board of Examiners of the Scottish Universities have just issued the statistics of passes and failures in the recent preliminary examination in Arts and Science and in Medicine of the four Scottish Universities. Detailed tables are given of the passes, etc., in the various subjects at each University. The following are the more important:

University.	Total Number of Candidates.		
	Entered.	Failed.	Passed.
1. University of St. Andrews	7	3	4
2. " " Glasgow	99	51	48
3. " " Aberdeen	23	12	11
4. " " Edinburgh	136	64	72

ARTS AND SCIENCE.

The following table shows what percentage the number of failures is of the number of candidates in the three subjects in which passes are allowed on more standards than one in the several Universities, and in the four Universities taken together:

Subject.	St. Andrews.	Glasgow.	Aberdeen.	Edinburgh.	The four Universities.
Intermediate and Higher Mathematics ..	50.00	51.56	28.00	38.18	42.54
Higher Latin ...	34.05	17.21	12.00	24.78	21.25
Higher Greek ...	13.59	15.48	12.25	7.69	12.92

The following table shows what percentage the number of passes is of the number of candidates entered for four subjects in the several Universities, and in the four Universities taken together:

	St. Andrews.	Glasgow.	Aberdeen.	Edinburgh.	The four Universities.
Percentage of					
.....	57.14	42.11	52.00	50.41	47.47

The last time the Joint Board of Examiners issued such statistics we were flooded with a series of ill-informed letters and paragraphs in which it was sought to prove that this and that university or university town stood highest or lowest in matters educational. It may be as well, therefore, to point out that any inferences from these statistics as they now stand are of necessity entirely fallacious, and for this reason: A great many of the best students at Edinburgh and Glasgow never appear for the Preliminary Examination at all. They qualify themselves by taking the "leaving certificate," and very often they take the higher grade-leaving certificates, which means a much more severe examination than the "Preliminary."

It is a fact that most of those who gain bursaries at Edinburgh are candidates who have thus never entered for the ordinary preliminary. The proportion of candidates who take the leaving certificate in place of the preliminary is very much higher at Edinburgh and Glasgow than at St. Andrews and Aberdeen.

Then again a great deal of misconception exists as to the mode of the preliminary examination. The facts are these. The papers are drawn up by the Joint Board of Examiners. The examinations are held simultaneously in the four Universities. The papers at each centre are examined by a set of examiners at that centre. But after this has been done, and this is the important point, there is a meeting of the Joint Board lasting one, two, or even three days, at which all papers in all subjects which come near the border line of pass or fail, say from 42 to 58 or thereabout, are taken up *seriatim* and are valued marked on by the whole body of examiners. Thus it comes about that there is as nearly as can be a uniformity of standard for the four Universities, and therefore, the statements that the examiners here or there are more lenient than the examiners elsewhere are quite worthless.

As an illustration of how the leaving certificate examination modifies these statistics, one instance may be taken. The percentage number of passes in French stands in these tables thus:

St. Andrews...	58.33
Glasgow	25.00
Aberdeen	55.00
Edinburgh	20.69
And in the four Universities taken together	32.48

Judged from this table, Edinburgh and Glasgow occupy a melancholy position. But French is one of the favourite subjects in the leaving certificate, and, were the statistics of the latter placed along with those of the Preliminary, the two younger Universities more than win their spurs.

THE "INDEX MEDICUS."

FROM the last circular issued by Dr. Billings and Dr. Fletcher there seems every prospect that the plan for continuing the *Index Medicus* will be successful. The final decision is to be sent to subscribers by December 1st next.

The points on which the editors now wish to have the opinion of subscribers are: (1) Shall the new series begin with January, 1896? or (2) Shall it begin with May 1st, 1895, thus taking up the work from the date at which the former publication stopped? If the latter plan be recommended and adopted, it is thought that the back material might be got together and issued in one part about March, 1896; in this case subscriptions would run from May 1st to April 30th in each year. If the former plan be decided upon subscriptions will run from January 1st to December, 1896. Inasmuch as all the published volumes go with the year, it seems that to continue this plan will be more satisfactory than starting a series which will run across the years. At any rate it is sincerely to be hoped that now we are so near to getting the continuation of the *Index*, it will not fall through for want of the few subscriptions needed to place the work on a sound financial basis.

PORTSMOUTH MEDICAL UNION AND THE CLUBS.

THE battle of the clubs is still in progress in Portsmouth, and we are glad to know that the resident members of the profession are still firm and united. The election of medical officers to one of the largest lodges in the town will take place in a few days, and it is a matter of great regret that there are already four outside candidates in addition to the present medical officer, who is seeking re-election on the old terms, namely 4s. per annum for members of all ages. During the last few days several medical men have visited Portsmouth for the purpose of applying for the appointment, but they honourably retired directly the cause of the vacancy was explained to them, and we sincerely hope that their example will be followed by all the other candidates before the day of election. The resident members of the profession have joined hands for the purpose of preventing fresh burdens being added to the duties of lodge surgeons, for which the remuneration is already poor and inadequate; and the conflict therefore must be regarded as no mere local agitation, for the issue will probably have far reaching results, and may touch the

interests of thousands of the general practitioners in all parts of the country. We sincerely hope that the outside candidates will be led to see the unenviable position they are seeking to occupy, and that the only straightforward course now open to them is to retire from the conflict at once, and in this way help their professional brethren to obtain a complete victory over the retrograde and unjust scheme with which they are threatened. We shall await the result of this conflict with the greatest interest, for success will exhibit the power of professional union, and will exercise upon other lodges a wholesome influence by checking future attempts to add unfairly to the labour, and at the same time reduce the remuneration, of their medical officers.

THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS, DISTRICT OF ENGLAND.

A MEETING of the Committee of the Association of Fellows of the Royal College of Surgeons of England, was held on November 13th, 1895; Mr. TIMOTHY HOLMES, in the unavoidable absence of Mr. George Pollock, in the chair. The minutes of the last meeting having been read and confirmed.

Mr. PERCY DUNN (Honorary Secretary) reported that as it had been found impossible to summon the members for the annual meeting as arranged at the previous meeting of the Committee, it had become necessary to fix a later date for that purpose, as well as for the preparation of the agenda to be submitted to the meeting.

After some discussion it was agreed that a meeting of the Committee should be called for December 4th, and that the annual meeting be definitely fixed for December 11th, 1895.

A letter was then read from Major-General Graham, Secretary of the Civil Rights Defence Committee, asking the Association to appoint a representative to act upon his Committee, and requesting the Committee of the Association to receive a deputation from the Civil Rights Defence Committee.

A letter was also read from Mr. R. B. Anderson in support of the above application from Major-General Graham, and containing a short statement of the main facts of his case.

A resolution was unanimously passed agreeing to receive the proposed deputation, and the Honorary Secretary was instructed to write to Major-General Graham to this effect, and at the same time to state that the Committee would be prepared to receive the deputation at 25, Grosvenor Street, W., at 5.30 P.M., on December 4th.

Mr. Anderson having expressed a desire to join the Association, he was duly proposed, seconded, and unanimously elected a member thereof.

After some discussion upon this case the following resolution was agreed to:

That the Committee of the Association of Fellows beg to express their warm appreciation of the action taken by the Council of the College of Surgeons, as representing the College, in the matter of Mr. Anderson's attempt to vindicate his legal rights as a Fellow of the College. They sympathise entirely with Mr. Anderson, and intend to bring his case before the Association with a view to appoint a delegate to act upon their behalf on the Civil Rights Defence Committee.

The Honorary Secretary was directed to forward a copy of this resolution to the Secretary of the College for presentation to the Council at their next meeting.

With reference to the appointment of a representative upon the Civil Rights Defence Committee, it was decided that as this was a new departure it would be advisable to defer its consideration until the annual meeting.

It will be remembered that last June Mr. T. R. Allinson was summoned at the Marylebone Police Court for using the description of L.R.C.P. and the title of Licentiate in Medicine, his name having been erased from the *Medical Register* in May, 1892. The magistrate inflicted a fine of £20 and £10 10s. costs. An appeal was entered, but we are informed that it is not being proceeded with. The case was regarded as a test case, and may be of much importance as a precedent.

THE EDUCATION OF THE STUDENT IN PRACTICAL MIDWIFERY.

By ROBERT REID RENTOUL, M.D.

THAT the education of the student in practical midwifery is sadly neglected, when we consider the attention which he is compelled to give to medicine and surgery, few practical persons will dispute. The fact, however, that in his future practice this student will be brought into much closer relation with midwifery and diseases of infants, should induce the medical authorities to look much more closely into this question; one which so intimately bears upon the lives and health of women and infants.

Sir W. Priestley, in the *BRITISH MEDICAL JOURNAL* of August 3rd, 1895, p. 284, is reported as having said, when speaking of puerperal mortality: "While the great advance has been made, however, in the institutions, I regret to say that progress of a like kind is not taken place in private practice. The later researches of *Bon-Saxall* have made it clear that there is a large preventable mortality among puerperal patients attended at their own homes, and if this continues it may become a standing reproach to us that women delivered in lying-in hospitals are actually safer than those confined in their own homes, which at one time was quite the reverse."

Granted that the above statement is so correct as to justify its publicity before the annual meeting of our Association, it must follow that when the chief medical authority in the British Empire recommends that students be admitted to their qualifying medical examination after having personally conducted only three confinements, something is sadly out of joint.

It is more than a pity that the traditional hatred which some Fellows of the Colleges bear to the practice of midwifery should still linger among some of those on our General Medical Council. Unfortunately the lives of thousands of mothers and infants have been sacrificed to this unmeaning hatred. In 1733 the Fellows of the Irish College of Physicians ordered that no one practising midwifery should be granted their diploma. Consequently they made themselves a laughing stock by refusing it to Sir Fielding Ould. Why did these Fellows think it degrading for a medical practitioner to practise midwifery? In 1765 the Fellows of the Edinburgh College of Physicians, ruled that no one could be admitted a Fellow whose "common business it is to practise midwifery;" and, further, that if any Fellow practised any of these "low acts" he was to be degraded. In 1811 the Fellows of the London College of Physicians actually went to such bitter extremes as to order that no practitioner should be made a Fellow if he practised midwifery. In 1843 the Fellows of the College of Surgeons of England also took this down-grade track, and ordered that no Fellow would be admitted to the Council of the College if he practised midwifery. On May 2nd, 1827, the London College of Physicians, in an official document to the Secretary of State to the Home Department, when speaking of midwifery, characterised it as "an art foreign to the habits of gentlemen of enlarged academic education"! It is little wonder, then, that when these self-styled leaders of a humane calling acted in this careless manner the death-rate in childbirth was enormous. In 1783 the Fellows of the London College recognised partly their gross blunder, and began to grant their single diploma in midwifery; while in 1838 the College of Surgeons of England began to grant its single diploma in midwifery, and to those who had neither a medical nor a surgical qualification. Strange to say, those who had only this diploma of the Royal College of Surgeons of England were permitted, by the Medical Act, 1858, and up to 1896, to have their names registered in our *Medical Register*.

Fortunately in 1886 a fresh move was made, with the view of placing midwifery upon the same high level as medicine and surgery; from that year it was enacted by the Medical Act that on and after 1887 no one could have his name placed upon the *Medical Register* unless he had passed a qualifying examination in the three subjects of Midwifery, Medicine, and Surgery. This enactment, which has done away with the singly-qualified practitioner, was forestalled

by the English Local Government Board in 1859, and by the Irish Board in 1862, when they ordered that all candidates applying for the post of Poor-law medical officer must be doubly qualified—that is, in both medicine and surgery.

Many of us complain that the General Medical Council has for so far failed to carry out the true meaning of the Medical Act, 1886, because it fails in reality to place midwifery on the same level as medicine and surgery. It can be readily seen, by looking into the certificates required by the various examining bodies, that these are far more exacting in the case of the study of medicine or surgery by the student during his five years than they are in the case of midwifery. Section 3 of the Medical Act, 1886, enacts that "the standard of proficiency required from candidates at the said qualifying examinations shall be such as sufficiently to guarantee the possession of the knowledge and skill requisite for the efficient practice of medicine, surgery, and midwifery." There is nothing in this enactment which would lead any person to believe that the study by the student, and his examination in midwifery are to receive much less attention from the medical authorities than does medicine. For instance, the student who wishes to enter for the M.B. Durham University must, as regards his study of medicine, show (a) attendance upon lectures on medicine, 12 months; (b) clinical medical lectures, 12 months; (c) medical hospital practice, 18 months; (d) medical clinical clerkship, 6 months; and (e) *post-mortem* demonstrations, 24 months. But as regards the study of midwifery, he has only to show (a) lectures on midwifery and diseases of women and of children, 6 months; (b) clinical obstetrics, 3 months; and (c) 20 cases of labour.

A study of the mortality statistics of childbirth will not justify our General Medical Council in ignoring the vast importance of a proper training of the student in practical midwifery. Even "natural labours" are no trivial occurrences. In 1893, in England and Wales, of a total deaths of 569,958 persons, 5,950 were women who died from puerperal fever and the other accidents of childbirth, that is, at least 1 death in every 95 of the total deaths was that of a woman in childbirth. From 1871 to 1893 no fewer than 48,374 mothers died from puerperal fever, and 50,211 from the accidents of childbirth in England and Wales. This is a shameful state of affairs. But how much higher would these statistics be if they were correct records? The Registrar-General has expressed constantly his regrets as to the untrustworthiness of the puerperal mortality returns, while McClintock has said that "one-fourth is not too much to allow for deaths omitted in the registration returns of deaths in childbirth."

As regards particular confinements, Duncan has shown that 1 in every 15 women in her first confinement dies. Thus the maternal mortality is actually much higher than that following major surgical operations. Yet the General Medical Council seems to refuse to recognise the practical bearing of these fearful statistics. In the same way the death-rate from puerperal fever is very high, and partly because the student has to work up his knowledge in "midwifery, diseases of women and of infants" in six months. If any support were required for my contention that the General Medical Council should see its way to seriously study this vital question, a perusal of the sick rate of maternity and of the heavy infant death-rate after midwifery operations will give due support.

For some time past a few earnest men have tried to rectify this lamentable state of affairs. When Dr. Glover brought the subject before the General Medical Council in 1891, Dr. Athill said: "I experience a feeling akin to shame at having to second so obvious and so necessary an improvement in the training of the student." Dr. Kidd said that "the requirements were woefully inadequate." The requirement is, that the student must have conducted personally only three cases of labour before being admitted to his final medical examination. Dr. Haughton said: "The previous discussion ended in a miserable fiasco—a fiasco which made him positively ashamed of the General Medical Council." Sir W. Foster said that "the regulations of the Council in respect of midwifery were the subject of scoff and satire"; while Mr. Wheelhouse said he "regarded it as little short of a reproach to the Council, that it should be said that to regard three cases

as sufficient instruction for a candidate in obstetrics," and "that obstetrics were better taught forty years ago than at present." These remarks, made by members of the General Medical Council, will surely make it reverse its vote on Dr. Glover's motion of 1891, when he was beaten only by 12 votes to 10. When Dr. Murdoch Cameron says: "A chapter of horrors might be written upon mismanagement of labour, and in which only the mystic letters appended to the operators' names protected them from prosecution. If such men bungled their surgical cases in the same way they would soon find themselves in a court for malpraxis," surely his words should be attended to. And when Dr. A. J. H. Barbour, acting as Inspector of Midwifery examinations, under the appointment of the General Medical Council, in 1888, reported: "In concluding this general commentary, I desire to state my opinion that none of the examinations come up in all points to such standard of proficiency as appears attainable by the methods here indicated," it is time that the General Medical Council and the medical examining bodies had taken action. The facts also that some of the examining bodies accept certificates of attendance from students who have "been present" at confinements, under the teaching and instruction of a midwife; while the number of rejections of students at their midwifery examinations all point conclusively that the requirements of the General Medical Council bearing upon the so called education of the student in midwifery, are bearing a sad result.

If the examinations themselves of students in midwifery could have some educational value, one would not be inclined to pay so much attention to the previous clinical instruction. In this country, however, the qualifying examinations comprise only a number of paper questions and an oral examination. Abroad it is very different. In Germany, the student for his final examination must conduct, on his own responsibility a confinement before the examiner, and send in a written report the day after. For the next seven days he must visit the woman twice daily; and, if the patient die, he must make a *post-mortem* examination and send in a report. If such a plan were followed in this country, there would be a steady fall in maternal deaths after confinement.

In the BRITISH MEDICAL JOURNAL of September 28th, I give a table, showing the requirements of the different examining bodies as regards the study of midwifery, and also the motion moved and seconded by Drs. Glover and Atthill. I hope that when this motion comes up again, it will be made more definite; that it will recommend that the student must himself "personally conduct" at least thirty labours; that he must do so under the "direct supervision" of a registered medical practitioner, and not by himself or with a midwife; and that the name and address of the patient, the date of the confinement, and the name of the supervising practitioner be entered upon his certificate of attendance. If this course be followed, then there will be a lessening in the number of fraudulent certificates, while the General Medical Council will have done its duty to the public, and especially to pregnant women and to infants.

ASSOCIATION INTELLIGENCE.

ELECTION OF MEMBERS.

Any qualified medical practitioner, not disqualified by any by-law of the Association, who shall be recommended as eligible by any three members, may be elected a member by the Council or by any recognised Branch Council.

Candidates seeking election by a Branch Council should apply to the Secretary of the Branch. No members can be elected by a Branch Council unless their names have been inserted in the circular summoning the meeting at which they seek election.

FRANCIS FOWKE, General Secretary.

LIBRARY OF THE BRITISH MEDICAL
ASSOCIATION.

Members are reminded that the Library and Writing Rooms of the Association are fitted up for the accommodation of the

members in commodious apartments, at the office of the Association, 429, Strand. The rooms are open from 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 2 P.M. Members can have their letters addressed to them at the Office.

BRANCH MEETINGS TO BE HELD.

BATH AND BRISTOL BRANCH.—The second ordinary meeting of the session will be held at the Grand Pump Room Hotel, Bath, on Wednesday evening, November 27th, at 7.30. Dr. Carey Coombe, President. The following communications are expected: Dr. Geo. Barker 1. Perforation of Appendix in Enteric Fever. 2. Perityphilitis: Local Progress. Mr. J. Nicholl Clarke: 1. Sequel to Case of Trephining to Remove Growths of Cerebral Tumour. 2. Case of Birth Palsy, in which an Operation was performed. Mr. C. Gaine: On some forms of Stoma, and on the Retention of Diseased Teeth and Stomps, which are not amenable to Conservative Treatment. Mr. Basil Trevelyan: A Brief Comparison of Young and Old Primiparae. Mr. T. G. Stock: On a Case of Scapula, with epaulet.—W. M. BRAUMONT (Bath), J. MICHELL CLARKE (Bristol), Honorary Secretaries.

SOUTH EASTERN BRANCH: EAST SUSSEX DISTRICT.—The next meeting will be held at the Hospital, Hastings, on Thursday, November 1st, at 3.30 P.M. Dr. Allen (President of South-Eastern Branch) in the Chair. Dinner at 5.30 at the Grand Hotel. Charge, 6s.; exclusive of wine. Professor Corfield (London) will give an address on The Pathology of Towns. Mr. Papillon and Dr. Rodmayne will show a collection of Cases. Dr. Willis will read notes of a Case of Gravel's associated with suppurative Tabloids. Mr. Lawson will speak on the Connection between Disease and Operations upon the Female Pelvic Venous and Effusion into the Pleura.—J. W. BATTERHAM, Honorary Secretary, Bank House, Grand Parade, St Leonard's.

STAFFORDSHIRE BRANCH.—The first general meeting of the season will be held at the North Stafford Hotel, Stoke-on-Trent, on Thursday, November 28th. The president, Dr. Geo. Field, will take the chair at 8.15. Agenda: Exhibition of anatomical specimens. Living Cases, New Instruments, etc. Papers:—Dr. McAlindow, Falcid-Gulbar Parafalad; Dr. Hallon: Notes on a case of Nephro-lithotomy. The treatment of Stricture of the Esophagus by means of Y. J. L. Dr. Mr. A. V. Griffiths: A case of Inversion of the Uterus. There will be a dinner (as usual) exclusive of wine) at 6 p.m., after the meeting. J. WILKES BLOWER, Honorary Secretary, Stafford.

NORTHERN COUNTIES OF SCOTLAND BRANCH.

The autumn meeting of this Branch was held at Forbes on October 23rd. In the absence of the President, Dr. CHARLES ADAM, of Elgin, presided.

Communication.—A paper was read by Dr. GEDDES, of Nairn, on Reflex Vomiting, illustrated by two cases of mitral stenosis, in which the only symptom was persistent vomiting, and which were both treated by diffusive stimulants with the best results. Dr. Geddes suggested that the cause of vomiting was due to congestion of the brain, either as acting by pressure on the brain directly, or through the general circulation, and in either case setting in action the vomiting centre. The paper was discussed by Dr. TAYLOR, Dr. DUGUID, Dr. KERR, Dr. DE WATTEVILLE, and the CHAIRMAN, and Dr. Geddes was thanked for his paper.

Medical Clubs.—Dr. MUNRO MOIR, of Inverness, read a report by the Subcommittee appointed at last meeting to consider the question of medical club abuses. The subcommittee had sent out 100 circulars requesting answers to certain queries, but had received only 61 replies. These replies were analysed, and the report went on to state that "the Committee regret that a great number of their professional brethren have not answered the circular. As it is only by unanimity that the present cheap system of club practice can be done away with, they shall hope that a greater interest in this matter will be evinced by the profession. At present only Cork, Portsmouth, and Inverness have made a decided stand. All must be aware of the gallant fight our brethren in Cork have made in their endeavour to bring matters to a more satisfactory basis. They found that the medical clubs in Cork were much abused, and many members in receipt of comfortable incomes joined these societies, and though well able to pay as private patients took advantage of their club membership, and received medical attendance for a few shillings a year. The Committee consider that the only means of solving this difficulty is by organisation, and to obtain this we must be unanimous. We, as members of the British Medical Association, look to the Council of the Association for help—pecuniary assistance if necessary. Then the different Branches should take the matter up. The Committee make the following suggestions: The minimum fee per head

should be 5s., but this not to include medicines. No family branch of any society to be encouraged or countenanced. A medical examination to be made of every candidate for admission to a society, and a fee of not less than 2s. 6d. to be paid. No married member earning over £2 per week to be eligible for membership, and no unmarried member earning more than 30s. to be eligible." The report was approved of, and the whole question was again remitted to the Committee to prosecute combined action among all professional men in the North of Scotland.

Dinner.—The members afterwards dined together, having previously had an excursion along the banks of the River Findhorn, then in great beauty.

HALIFAX, NOVA SCOTIA, BRANCH.

A LARGELY attended meeting of this Branch was held on Thursday, October 17th, at Halifax, Dr. THOMAS TRENAMAN in the chair.

New Member.—W. H. Hattie, M.D., C.M., was elected a member of the Branch and of the Association.

Antigen Treatment of Diphtheria.—DR. CAMPBELL and CHRISTOPHER reported cases of diphtheria treated by antitoxic serum. A prolonged and interesting discussion followed, in which the following took part: Surgeon-Colonel O'DWYER, DR. FAIRBELL BLACK, ALMON, REID, McMILLAN (of Pictou), CARLETON JONES, and others.

GRAHAMSTOWN AND EASTERN PROVINCE BRANCH.
The usual bimonthly meeting was held in the Bacteriological Institute, Grahamstown, on August 29th; Dr. W. ATHENSTON in the chair.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

Communications.—Dr. SAUNDERS read a paper on a case of Anemia due to *Ankylostoma Duodenale*. Dr. EDINGTON suggested the possibility of its being connected with the sleeping disease of the Congo natives. During discussion it was noted that the patient under discussion had visited the Zambesi.—Dr. EDINGTON read a paper on the Etiology and Pathology of Horse Sickness, and illustrated the same by naked-eye and microscopic specimens.

Vote of Thanks.—The usual vote of thanks was recorded to the Chairman.

SPECIAL CORRESPONDENCE.

PARIS.

Hospital Districts.—The "Alcoholism" Question.

THE Municipal Council continues its debates on the new regulation, according to which Paris has been divided into districts, and the out-patient department placed under the charge of young medical men and a special staff of dressers, both of whom receive salaries. The new system has already had some undesirable results. A patient sent from Lariboisière Hospital to the Ophthalmo Hospital died on the way. A female patient, with a dislocated shoulder, remained three days without medical help. Another sufferer was refused admission, notwithstanding a free use of the telephone, because she lived on a river boat that was not stationary. Another case of refusal is chronicled because the patient slept at night asylums. An unfortunate woman who suffered from serious intestinal ulceration was on the point of being sent to M. Peyron at the Assistance Publique to ask his permission to be treated at the St. Louis Hospital. These cases are authentic, and are published under the responsibility of Dr. Marchand, Surgeon to the St. Louis Hospital. Dr. Hartmann, of the Bichat Hospital, cites the following case as one among many. A woman with a baby in her arms applied for admission at the Bichat Hospital, the hospital of her district. She was not admitted because there was not a *criche* at that hospital. She was told to go to the Hôtel Dieu. With difficulty she reached that hospital; when there she was asked her name and address, and told to return the next morning at 8.30, which she did only to be told to go back to Bichat, the hospital of her district. The patient objected that there was no *criche*, and that she had already been sent from the Bichat

Hospital to the Hôtel Dieu. "Never mind, go back," was the reply. The poor mother consequently set out to pay a second visit to Bichat Hospital, scarcely able to walk, carrying her baby in the pouring rain. She arrived there five minutes too late. The consultation was over. The unfortunate woman, thoroughly exhausted, fell fainting on the pavement. Dr. Hartmann arrived at the hospital at the moment. Seeing a crowd, he asked the reason. On being informed, he advised those present to sign a petition asking the municipal councillors to revise the new regulation concerning the admission of hospital patients. The suggestion was adopted, and the petition has 400 signatures. Dr. Hartmann proposes that a district hospital shall be obliged to admit the patients of its district, but that they have the power to go elsewhere if they wish. The division of Paris into hospital districts obliges the sick poor to be provided with documents establishing their identity. This troublesome formality wastes time and costs money. Functionaries of the Assistance Publique stop them at the doors of the hospital in order to examine these papers. If no tender-hearted official be present to recognise that their case is urgent, they are mercilessly sent to their district hospital, perhaps to find it full; or, the consultation over, to be told to come back the next day. A number of hospital surgeons and physicians have been interviewed concerning the new regulation for the out-patient department. Their opinions can be summarized as follows: Apart from the annoyances and humiliation inflicted on officers of long standing hitherto considered to be masters in their wards, observance of the new regulation incurs a considerable expense. Previously the out-patient department was no extra expense to the Assistance Publique. The salary of the assistant surgeon or physician is £104 per annum. The *chefs de service* was and is paid £20, added to which a fresh subordinate official is taken in each hospital, who is lodged, fed, and paid £16 a year. It is this subordinate official who, when the consultations are not going on, decides if the patients who apply for admission are to be admitted or not. A policeman is also paid to be present at the door of the consultation room: thus the increased expense of each hospital amounts to £120. The debates going on at the Municipal Council meetings clearly show that the present regulations will be considerably modified.

M. Siegfried, member of the Chamber of Deputies, and formerly Minister of Commerce, is taking an active part in the struggle against alcoholism. At a meeting held at the rooms of the Société des Savantes he described his plan of action, which is the same as he adopted in 1889 with success in the question of working men's dwellings. He will lay before the Chamber a proposition signed by many other deputies, that a law controlling wine shops and the sale of intoxicating liquors should be enacted. In a lecture he delivered in the female alcoholic section of the Villejuif Asylum, he explained the dangerous action of alcoholic drinks: the "*liqueur des dames*," made from kernels, supposed to be innocent, is extremely dangerous: Dr. Laborde nearly lost his life whilst making experiments with it. M. le Conseiller Rau proposes that cases of drunkenness should be considered as offences, and be judged at the *tribunaux correctionnels*, which have the power of inflicting only slight punishments: repeated drunkenness could be more severely punished. Drunkenness, M. Rau considers, should be regarded as a reason for rendering punishment more severe in cases of bodily injuries and homicide. Furthermore, a law obliging drunkards to be kept under observance in special asylums after their liberation is claimed by M. Rau; such a law is already in force as regards vagrants.

BERLIN.

The Law as to Secret Remedies in Prussia.—Medical Men and Military Service.—A New Policlinic.—Decoration of Professor Loeffler.

It is a general saying that secret remedies ("*Geheim-mittel*") are forbidden in Prussia. But as a matter of fact no law on the subject exists. Police regulations forbidding the sale and advertisement of "*Geheim-mittel*" have been issued at different times in the different provinces of the kingdom, but the nature of a secret remedy has never been defined and legally fixed. Thus, for instance, the editor of a most

respectable Berlin paper, the *National Zeitung*, was sued by the police a short time ago because he had allowed an advertisement to appear in which a tea—the ingredients of which were enumerated—was recommended. The editor insisted on a legal decision, and of course the judge decided in his favour. This case is by no means an isolated one, and there is no present prospect that the confusion of ideas on the subject will be cleared up, for the newest regulation published by the Police President of Berlin for the province of Brandenburg (which includes Berlin) says: "The public advertisement of secret remedies, which are intended to prevent or cure human diseases, is forbidden," without giving any information as to what is a secret remedy and what is not.

In the German army doctors of medicine, though they serve a full year like all other "Einfährig-Freiwillige," are only kept under arms for six months, and do assistant medical work in their second half-year. The army authorities have lately decided to again call in doctors for a short period of service, in the years following their dismissal from active service. Every year 300 assistant doctors (*Assistenten-ärzte*) of the first class are to be called in for a period of 28 days, and 500 "Unterärzte"—a lower grade in the military medical scale—for a period of 42 days. This announcement has caused no little excitement; young doctors, who find it difficult enough to build up a practice even when constantly on the spot, are anxiously asking themselves whether it will not fade away altogether if they are obliged to leave their patients for four, or even six, weeks at a time.

A new surgical policlinic, in connection with the Berlin University, will be opened very shortly. Professor König, the successor of Bardeleben, is to be its head, and his assistant, Professor Hildebrand, who follows him to Berlin from Göttingen, its chief surgeon.

Professor Loeffler, of Greifswald, the discoverer of the diphtheria bacillus, has received from the French Government the officer's cross of the Legion of Honour.

ROME.

The Anti-Anthrax Serum.—The Policlinico.

DR. SCLAVO, the chief of the bacteriological laboratory of the Direction of Health, has published an important preliminary note on the Preparation of Anti-Anthrax Serum. He has made experiments to ascertain whether the serum of animals distinctly receptive to anthrax, but rendered immune against it, would have preventive and therapeutic properties. He selected the sheep as the producer of the serum, and tested the new qualities acquired by the serum in the rabbit. In March, 1895, he undertook the immunisation of a sheep, commencing the treatment with two Pasteur vaccines, and gradually increasing the degree of immunity, injecting subcutaneously increasing quantities of a most virulent anthrax bacillus. On September 12th the sheep bore, with a slight increase of temperature, the injection of all the anthrax material developed in seven cultures made in agar. Six days after he obtained, by bleeding from the carotid artery, the serum which served for the experiments on the rabbit. In June he injected 1 c.cm. of anthrax culture in broth into a female lamb. In spite of the strong dose of the culture employed—certainly more active than the two Pasteur vaccines—the animal survived, presenting marked reaction at the place of injection. The lamb, in consequence of the treatment, acquired an immunity against anthrax, which would gradually increase with increasing doses of most virulent anthrax culture. The results obtained with the sheep's serum may be thus summarised: In a dose of 2 c.cm. it preserves from death rabbits (weighing from 1 to 2 kils.) which received, from 12 to 24 hours afterwards, 1 c.cm. of anthrax culture. This quantity of culture, much superior to the minimum lethal dose, killed in about 40 hours the control rabbits. With 5 c.cm. of serum he saved rabbits by injecting simultaneously the serum and the anthrax culture. The therapeutic results obtained with serum injected 6, 12, 18, and 24 hours after the above dose of culture were also remarkable. In an experiment with 6 rabbits, 2, which had received, after 18 hours, respectively 5 and 10 c.cm. of serum, died in 5 and 6 days; the 2 rabbits which had the same quantity of serum after 12 hours, and a third in which were injected 10 c.cm. of serum after 6 hours, still lived. A rabbit treated with 5 c.cm. of serum,

likewise after 6 hours, died on the ninth day; but the necropsy showed numerous cysticerci in the peritoneal cavity and extensive coecidiosis of the liver. An attempt was made to treat a rabbit after 24 hours from the injection of the anthrax germs, but the animal succumbed to the disease at the end of 8 days from the inoculation. In the various experiments the serum was always injected under the skin of the back, whilst the anthrax bacillus was introduced into the subcutaneous tissue of the abdomen. The lamb's serum also possesses preventive and therapeutic properties, but much inferior in degree. From the results obtained, Dr. Sclavo believes that there is ground for hope that anthrax both in man and in domestic animals may be combated by serum-therapy.

There appears to be some grounds for the hope that the Policlinico will be completed within a measurable time, as it is stated that the Minister of the Home Office has nominated a Commission under the presidency of Senator Professor Durante to draw up a project in relation to its completion.

BRISTOL.

Medical Library.—Floods.—The Anniversary Dinners.—Prosecution under the Medical Act.

THE medical library of University College contains over 14,000 volumes. According to the annual report of the Honorary Librarian (Mr. L. M. Griffiths), read at the opening meeting of the Medico-Chirurgical Society, the library, properly speaking, is composed of four libraries, amalgamated in order to centralise the books and to avoid the unnecessary multiplication of modern textbooks that would otherwise occur. The books from each library are labelled differently, so that should the necessity occur at any time for dissolving the association, they could be returned to their owners. The initial step was taken in 1891, when the Society started a library of its own, and the collection was rapidly augmented by large presents of books from members and others, especially the British Medical Association, and by purchases made from donations of money. For two and a-half years a room was rented at the Literary and Philosophic Club, but as further space was required in consequence of the rapid growth of the library it was agreed by a vote of the Society to combine with the Faculty of Medicine and house the books in the new Medical Department of University College, opened in 1892. Medical libraries also existed at the infirmary and hospital, and in 1894 both of these were added, making an addition of over 5,000 volumes. This combination of books, though it has resulted in the possession of several duplicate copies of some works, has made a most valuable collection of books. In the June number of the *Bristol Medico-Chirurgical Journal* a list of periodicals required to complete certain imperfect series was inserted, and it is hoped that in time the numerous serious gaps may be filled up. A large number of current periodicals—over 150 in number—are laid on the table in the library.

Owing to the heavy rainfall on November 5th a repetition of the floods of a year ago has happened. Over what is at ordinary times a small stream a culvert was built some years ago, but for some unknown reason the centre was made about three times as narrow as the entrance with the inevitable result that the flow of water is kept back and the culvert bursts. Several houses were flooded to the depth of some feet, and much destruction was done to garden walls.

The Colston celebrations took place on November 15th with the usual services, dinners, and speeches. The only unusual circumstance was the unveiling of the statue of the great Bristol philanthropist by the mayor. Of the three Societies, the only one which has any direct connection with medical work is the non-political one, the General, which last year gave 10s. to 1,070 lying in married women besides annuities of £18 to 38 persons. The President of this Society was Mr. J. Hancock Watkin, M.R.C.S. Eng., L.R.C.P. Edin., who announced that his collection amounted to about £200—no inconsiderable sum when it is remembered that all requests for contributions have to be made between November 1st and November 15th. The total sum collected by the three Societies was nearly £500.

On November 13th, at the Bristol Police Court, William Francis Jackson, of Meridian Place, Clifton, was summoned

for that he, not being a duly-qualified medical practitioner, had been practising and pretending to be a surgeon. There was another summons against him for pretending to be a doctor of medicine. Mr. S. L. Usher appeared to prosecute for the Medical Defence Union, and Mr. J. Nichols was for the defendant. Mr. Nichols stated that the summons had only been served on the previous night, and that he had only been instructed that morning. The case was adjourned.

CORRESPONDENCE.

THE BATTLE OF THE CLUBS.

SIR,—Our "battle with the clubs" here has reached this stage—that there are four outside competitors against the present holder. No local man is contesting against the present holder. There have been other candidates, but they have been induced to withdraw. The outside men are—Dr. Steel, Ashby-de la Zouche; Dr. Todd, Tabley Road, Hol-loway; Dr. Paul, West Cowes; Dr. Davidson, Spennymoor, Durham. The present holder refuses to take infants and girl juveniles under 1s. per annum.

May we ask your assistance in appealing in the columns of the BRITISH MEDICAL JOURNAL to these men, urging them to withdraw? I may perhaps add that the outside men have tendered for the infants and other juveniles at 2s. 6d., 2s., and 1s. 6d. per annum. There is absolutely nothing personal against the present holder. This battle was brought on by the lodge in question requiring of him to attend infants from 3 months and juveniles of both sexes to 15 years for 2s. 6d. per annum.

The local profession is united to a man. If we can only win this fight, there are many other reforms open to us with every chance of success.—I am, etc.,

T. FREDERICK PRABBE,

Honorary Secretary Portsmouth Medical Society.

Portsmouth, Nov. 17th.

* * We would strongly support this appeal from Portsmouth. As Byron apostrophised the Greeks: "Who would be free, themselves must strike the blow." Appeals to the General Medical Council, to the Council of the British Medical Association, or to any other central council to stop the existing systematic encroachments on the independence of the medical profession must be useless as long as members of that profession are to be found false to their own interests, false to the interests of the profession to which they belong, ready to accept terms utterly inadequate, we do not say to remunerate the services rendered, but to keep the body and soul of the club's servant together. The members of the Branches are in a good position to take local initiative.

THE ADMISSION OF WOMEN TO THE EXAMINATIONS OF THE CONJOINT BOARD.

SIR,—The issue upon which the recent decision of the Royal College of Physicians regarding the admission of women to its licence was arrived at was scarcely based upon the consideration of the rights and duties of the College. The question was not, whether women might be admitted to the profession of medicine, but whether the College should or should not determine whether female candidates were properly qualified for practice. The former question, whatever we may have thought about it thirty years ago, has long been settled in the affirmative by the formation of women's hospitals and schools and by the means afforded them of obtaining qualifications to practise from various corporate bodies in the United Kingdom.

As regards the second question, I venture to submit that the College, claiming to be the highest arbiter of medical knowledge and medical ethics in the profession, abrogates its legitimate functions by refusing to allow anyone, male or female, to subject themselves to the ordeal of the examinations, which are sufficiently severe in theory and in practice

to offer ample guarantees against the passing of unworthy candidates.

This is in no sense a question of gallantry. If women cannot pass our examinations they must be content to hold only what they perhaps estimate less highly as a diploma for practice. If the College of Physicians yields gracefully to the aspirations of some women and acknowledges established facts they will, in my humble opinion, increase their influence and in no way derogate from their high and legitimate position.

I trust that those who differ from me in this matter will give me credit that what I have written is prompted solely by the affection I bear to my profession and the grand old College of Physicians.—I am, etc.,

EDWARD H. SILVERING,

Manchester Square, W., Nov. 14th.

Twice Senior Censor, R.C.P.

THE BRITISH MEDICAL BENEVOLENT FUND.

SIR,—May I ask you to be kind enough to allow me to add the following to the list of contributions to the British Medical Benevolent Fund?

W. H. BROADBENT.

THE SANITARY CONDITION OF WINDSOR.

SIR,—Permit me to reply *seriatim* to the strictures of Mr. B. Denton upon the sanitary condition of Windsor.

1. And, first, I would like to say that the extracts which he gives from Dr. H. Airey's report of 1886 convey an unfair impression of its general tenour. For the report was considered by the then President of the Local Government Board to be in effect favourable to the sanitary administration of the borough.

2. The absence of public baths in a small town such as Windsor is not remarkable.

3. The statement that no hospital for infectious diseases has been built is not strictly true, for Windsor is provided with a small-pox hospital, which has been found to be very convenient and satisfactory. Several attempts have been made to find a suitable site for a fever hospital also, but without success. Windsor is hemmed in between the river and the Great Park, and the difficulty of finding an unobjectionable site for a sanatorium is unusually great.

4. Private slaughterhouses do exist in the town, but, as Mr. Denton ought to know, the district council has no power to remove them.

5. It is not true that the condition of the streets and roads is bad; on the contrary, they are generally excellent and well kept. The county surveyor has, indeed, recently reported the main streets and roads to be in satisfactory order. Possibly Mr. Denton observed two or three new roads which are unfinished, and have not yet been taken possession of by the authority.

6. The absence of a good riverside road has nothing to do with the sanitary condition of the town. Whether it would pay to construct such a road is the concern of the ratepayers alone.

7. Mr. Bailey Denton's surmise that "few of the houses of the better class would stand a sanitary test" is unsupported by any evidence. As a matter of fact every one of them has been inspected by our excellent sanitary inspector, and the drains of very many have been recently reconstructed; and the newer houses have been built subject to by-laws of exceptional stringency.

8. The "ditch" to which your Commissioner alludes is a watercourse which has not, at least for many years, been a nuisance. It is on Crown property, and the district council has neither the right nor the power to cover it over.

9. The courts mentioned by Mr. Denton have nearly all been much improved since Dr. Airey's visit. Haines Court, for instance, was opened out some years ago, and now contains only two cottages, clean and well kept, each having its watercloset. Your Commissioner's comment on Garden

Court is also quite inaccurate. Several of the old courts are cramped for space, but I have not been able to satisfy myself that I should be justified in condemning them as "dangerous to health so as to be unfit for habitation." They are generally well looked after, and overcrowding is rare. One court only was at the time of Mr. B. Denton's visit in a bad condition; in that case notices had been served upon the owner, and the work of amendment had, I believe, been already begun.

10. Windsor Town Council has no control over the course of the river, and is not responsible for the occurrence of occasional floods; nor can it prevent houses from being built on the low ground. But it has enacted a by-law, which, I believe, without precedent, that new houses must be raised above the level of the highest known flood.

11. There are no "slum areas" capable of being a danger to the health of the borough; and I must, in spite of Mr. Bailey Denton's demur, be allowed to point to statistics as a proof that the town is a very healthy one; for the general death-rate for ten years (16.8), the infantile mortality (112), the zymotic death rate (1.8), and especially the death-rates of scarlet fever, typhoid fever, and diphtheria, are all notably low. In calculating the general death-rate I have always made the due correction for the age distribution of the population. Why should you stigmatise my figures as "crude;" what "cooking" do they require?—I am, etc.,

EDWARD CASEY, M.D. Lond.,

Medical Officer of Health.

Windsor, Nov. 17th.

THE SCHOTT TREATMENT OF HEART DISEASE.

SIR,—Like Dr. Poore, I too was greatly struck by the reports of the enormous diminution of the area of dulness which followed a few minutes' immersion in a bath, or an equally short time occupied by the so-called Schott movements. So impossible did I think that this diminution of area dulness could be dependent on simple cardiac contraction that I went to Nauheim with the object of investigating this point, thinking that some error underlay the observation. My inquiry, extending over some days, was undertaken in a scientific and sceptical spirit, and resulted in my making the following observations, which to a great extent apply to Dr. Poore's very natural objections.

1. The diminution of cardiac dulness can be observed equally after the bath as after the therapeutic exercises.

2. The body was wholly immersed in the bath, so that the pressure of water must have been nearly equal over both chest and abdomen, and as the percussion observations were made after the bath, and the contracted area of dulness remained for a longer time (one, two, and three hours or more), the effect of a pressure of water on the abdomen is excluded.

3. By careful percussion of the lungs at the upper as well as the lower margins after baths and exercises I found no evidence of a special dilatation of the lungs, although it was in this direction that I naturally sought explanations of the phenomena observed.

4. When there is any remarkable diminution in the area of cardiac dulness, percussion shows that the diaphragm goes up proportionately to this diminution, which would not be the case if lung expansion was the cause of the diminished dulness. I made careful tracings of these conditions quite independently of Dr. Schott, and took the greatest care that they should be accurate.

5. A distended lung from increased thoracic expansion would move the apex beat downwards and outwards relatively to the ribs, enlarged abdominal organs upwards and outwards, but in cases after the baths and exercises, I found that the change took place (when the apex beat could be clearly defined) upwards and inwards.

Many excellent physicians have borne testimony to remarkable results from this treatment, and the public is now so much alive to it that I cordially agree with Dr. Poore that the whole subject stands in need of more careful consideration. Indeed, I think it is now a duty imposed upon all of us not to accept present statements, but to give the subject every consideration, and so prevent a great possible good falling into the hands of unscrupulous and uninformed pretenders.—I am, etc.,

Upper Brook Street, W.

ROBERT L. BOWLES.

SIR,—I have been much interested in the paper of Dr. Saundby and the letter of Dr. Poore on this subject; but, whilst being much struck with the calculation and remarks of Dr. Poore in relation to the reduction of the area of cardiac dulness following the baths and exercises advised by Dr. Schott, I should be glad to hear from Dr. Poore some explanation of the migration of the apex beat towards the middle line which undoubtedly takes place in some, if not all, cases of dilatation of the heart after both baths and exercises.

It is quite conceivable that the expanded lung may overlap the heart, and so reduce the area of dulness, but not so clear that this, or any other cause except actual reduction in the size of the heart, can move the apex beat from half an inch to one inch towards the middle line.

I am not prepared to assert that this is in any degree permanent, but am quite certain that the change does take place, and also that the pulse rate is reduced in frequency.—I am, etc.,

Weston-super-Mare, Nov. 12th.

D. BRADLEY.

SIR,—Dr. Robert Saundby's exposition of the rationale of the Nauheim treatment, though more in accordance with facts than any yet given, is yet, I venture to think, incomplete. Resisted movements benefit, I believe, by stimulating the heart and respiratory movements at the same time that they prevent the blood passing too rapidly into the systemic veins. The movements in question are performed, be it noted, while standing, when numerous muscles are already tonically contracted, and when a resisted movement is made not only are the muscles specially engaged in it tonically contracted, but there is an increased contraction of numerous others in order to preserve the equilibrium; in short the whole, or almost the whole, muscular system is thrown into a state of considerable tonic contraction.

Let us see what effect this has on the circulation. A large quantity of blood is attracted to the muscles; less, therefore, passes into the splanchnic system, and the splanchnic veins being moreover compressed by the contracted abdominal muscles, less blood flows from them into the lower cava. At the same time the outflow of blood from the muscles, in consequence of their veins being continuously compressed, is low. The inferior cava being likewise compressed, it follows that the total escape of blood into the systemic veins is low. Meanwhile the heart and respiratory movements, stimulated as they always are by muscular activity, are busy pumping and aspirating the excess of blood contained in the systemic veins and lungs into the systemic arteries, which become in consequence fuller and tenser, and continue to do so until the resisted movement ceases. The resistance to the arterial outflow being now diminished, there is a rush of blood from the distended arteries through the capillaries, and although the venous system tends to refill, much has been achieved, for the right heart has had an opportunity of shrinking and approaching its normal condition, and the accelerated capillary circulation has contributed to normal nutrition.

The good effects of the bath treatment may be explained on similar lines; but I have already exceeded my space, and as I have exhaustively treated of the dynamics of the circulation in relation to heart disease in a work shortly to be published, I need say no more on the subject here.—I am, etc.,

Devonshire Street, W., Nov. 17th.

HARRY CAMPBELL.

DIPHTHERIA ANTITOXIN AS A CULTURE MEDIUM FOR THE DIPHTHERIA BACILLUS.

SIR,—Your correspondent, W. A. Hollis, in reality proposes to Dr. Semple and myself the following dilemma: either (1) the injections of anti-diphtheritic serum may be useless, and, if so, the antitoxic serum may be a good cultivation material for the diphtheria bacillus, or (2) the injections of anti-diphtheritic serum are useful, and then it must follow on *a priori* principles that the diphtheria bacillus will not grow on antitoxic serum.

The only way of dealing with such an argument is to show that there is another possible alternative which we have no *a priori* reasons for rejecting. The alternative in question is that the injections of antitoxic serum may be useful, even though the antitoxic serum possesses no bactericidal power whatever. Now, since this is a proposition which probably

every bacteriologist is concerned to maintain, it may be well to show that its acceptance does not involve us in any contradictions. The matter will probably become perfectly clear to the reader if he will consider and compare the two following series of propositions: (1) Alcohol is produced by the yeast plant. The absorption of that alcohol into the system constitutes an "alcohol intoxication." Certain drugs, such as opium or bromide of potassium, do to some extent neutralise the effects of that "alcohol intoxication." A sugar solution constitutes an excellent culture medium for the yeast plant. (2) Diphtheria toxin is produced by the diphtheritic bacillus. Absorption of diphtheria toxin into the system constitutes the "diphtheria intoxication." Diphtheria antitoxins neutralise the effects of that "diphtheria intoxication." Serum is a good cultivation medium for the diphtheria bacillus.

Now, we are evidently no more entitled to infer *a priori* from the one series of facts that the presence of "antitoxins" in the serum would render it a bad culture medium for the diphtheria bacillus than we are entitled to infer *a priori* from the other series of facts, that the presence of opium or bromide of potassium in a sugar solution would render that sugar solution a bad culture medium for the yeast plant. In both cases the question is simply a question for experiment. —I am, etc.,

Netley, Nov. 18th.

A. E. WRIGHT.

DIPHTHERIA ANTITOXIC SERUM IN LONDON.

SIR,—Your note calling for statistical information of the treatment of diphtheria by serum in the Metropolitan Asylums Board Hospitals is not uttered any too soon. The ratepayers were promised the information after a six months' trial, and it is now going on for twelve.

It appears necessary to urge that these statistical reports should be not conjoint, but that that of each medical superintendent should be kept separate, as have been all those of former years.

There is already a difference of mortality under former treatment of something like 14 per cent. in the six hospitals which treat diphtheria under the Board, and it is possible that there may be an equal difference in the results under serum treatment. However desirable, therefore, it might be to group the figures, it would be obviously unfair not to give opportunity of studying the statistics of each hospital on a separate and individual basis.

There is one point further. In a leader which appeared in the *BRITISH MEDICAL JOURNAL* of August 24th, 1895, you admitted the justice of one of the contentions raised against full acceptance of the treatment as at present pursued—namely, "the want of uniformity in the strength of antitoxin serum sent out by different firms." It would in these circumstances be desirable that the first series of statistics should be confined to those cases treated by the serum supplied from the Institute of Preventive Medicine, the only source, I believe, up to a recent date; and not to mix up with them those that are, as now, injected with the serum provided by the laboratory of the Royal College of Physicians and Surgeons. —I am, etc.,

Mansfield Street, W., Nov. 16th.

LENNOX BROWNE.

THE PROPOSED GENERAL HOSPITAL FOR CAMBERWELL.

SIR,—A scheme is on foot to build a new general hospital for South London in Camberwell. The promoters are perfect strangers to Camberwell, and are endeavouring to secure a site in Coldharbour Lane from the County Council. A meeting was held last June at the Camberwell Vestry Hall, to which only the clergy were invited. The members of the vestry who happened to be present strongly objected to the scheme. The meeting was adjourned, and another has not since been held.

We, the undersigned medical officers of the Camberwell Provident Dispensary, consider a new general hospital in Camberwell is unnecessary for the following reasons:

1. That Camberwell is only a sleeping ground for the City workers, and no industrial manufactories are in the district.
2. That Guy's and St. Thomas's Hospitals are within easy reach, and that both have a considerable number of empty beds due to want of funds.
3. That the provident dispensary to which we are attached,

being in close proximity to the proposed site, is able to administer to the wants of the sick. It is one of the largest provident dispensaries in England, having about 14,000 benefited members, who are seen at the dispensary or attended at their homes by us. It is also one of the oldest, having been over thirty-three years in existence.

4. That the parish of Camberwell has recently expended a large sum on a new infirmary.

5. That the funds of existing hospitals being quite inadequate to keep open the whole of their wards, it would be much better to raise money for their assistance before building another hospital. —We are, etc.,

NORMAN B. ELLIOT.

C. PINEL GALLIE.

W. BEAMLEY TAYLOR.

FREDERICK NORMAN.

A. BRENCHLEY.

WALTER A. ATKINSON.

F. HORTON VILLANUEVA.

CAMPBELL BOYD.

HENRY B. SHILLINGFORD.

November 19th.

NEW METHOD OF CLEANING AND DEODORISING CATHETERS.

SIR,—I have read Mr. Mansell Moullin's letter with much interest, and I am glad to learn that he has tested my method of cleaning and deodorising catheters, which appeared in the *BRITISH MEDICAL JOURNAL* of January 19th, 1895. At the Royal Portsmouth Hospital this process has now been in operation for the past twelve months, with excellent results. We have not purchased a new boiler, but have utilised the long-discarded steam spray. Messrs. Maw, Son, and Thompson have, at my suggestion, attached to it three tapering tubes fitted with stopcocks, and capable of holding four catheters of different sizes. I shall be very happy to send further details concerning the contrivance to any hospital or surgical institution.

I again desire to accentuate the importance of manufacturing all catheters with solid points, terminating in flat surfaces within the tubes, just above the first perforation, for instruments with hollow ends can never be completely deodorised. Gum, elastic, and vulcanite catheters can be very conveniently made in this way with tapering and bulbous ends.

I am glad that Mr. Mansell Moullin has referred to the necessity of manufacturing soft catheters with perfectly smooth internal surfaces. I have used soft instruments of this description for many years, but unfortunately a large number are still made with rough and ragged interiors, to which urinary products and oily matter obstinately adhere, and it is, therefore, practically impossible to deodorise and keep them clean. —I am, etc.,

J. WARD COUSINS,

Nov. 19th.

Senior Surgeon to the Royal Portsmouth Hospital.

DIRECT REPRESENTATION ON THE GENERAL MEDICAL COUNCIL.

SIR,—Agreeing most fully with the general drift of your leading article on this subject, I should be glad if you would allow me to point out that several of us who served with the late Dr. Waters, of Chester, on the Medical Reform Committee, foresaw even then that the addition of five representative members to a Council made up so largely of corporation delegates was quite inadequate, and that the result would probably be what it has since turned out, to render them more or less impotent for good in the face of such a corporate majority.

I must confess that I am still of the same opinion with regard to the proposed addition of seven more direct representatives, and though, of course, in the unlikely event of the corporate delegates reversing their former decisions, such an addition might be accepted on the principle that half a loaf is better than no bread, it is quite certain, I think, that our representatives would still be outvoted on any question on which corporate interests might be supposed to clash with those of the profession generally. Hence it seems to me that if we have to go to Parliament, as we probably shall have, our demand should be for at least one half the Council to consist of direct representatives, the remainder being made up of Crown nominees and representatives of the licensing bodies. With regard to these latter the question should also be raised as to whether they ought not to be elected by the whole corporation rather than by a small governing body.

I venture to suggest to the Council of our Association that

the appointment of a small committee of, say six, to consider this subject is very desirable, and that if they could secure the services of Sir Walter Foster as chairman of such committee, it would be a great gain to the Association?—I am, etc.,
H. NELSON HARDY.

Dulwich, S.E., Nov. 20th.

WELL-TO-DO PATIENTS IN RATE-SUPPORTED HOSPITALS AND THE PUBLIC.

Sir.—No one can find fault with Mr. Osborn's remarks in the *BRITISH MEDICAL JOURNAL* of November 9th, but he omits to mention that the cause of abuse in, in a great measure, due to the action of medical men themselves. So many practitioners are so nervous and frightened over an infectious case—and, of course, the friends become so also—with the result that the first and only thought is the quickest method of getting the unfortunate patient out of the house, and so prevent the neighbours from knowing anything about the matter. The ambulance is sent for, and the medical man sees the last of what ought to have brought grist to the mill.—I am, etc.,

London, Nov. 14th.

EDWARD CARNALL.

OBITUARY.

RICHARD ROSS, M.D.,

Physician to the Belfast Royal Hospital.

THE most profound regret was felt in Belfast on Wednesday, November 13th, when it became known that Dr. Richard Ross had expired that morning. He had been in full work until about a week before his decease, and it was not generally known that his illness was of a serious nature. The cause of death was angina pectoris. Dr. Ross was a native of co. Monaghan, and received his professional education chiefly in Dublin. He took the L.M. of the Coombe Hospital so far back as 1847, and in the following year he became a Licentiate of the Royal College of Surgeons of Ireland. He was admitted to the M.D. of St. Andrews in 1850.

Shortly after obtaining his qualifications he undertook some work in the west of Ireland in connection with the prevailing cholera epidemic; but in 1850 he settled in Belfast, and soon came to the front. He was one of the first Poor-law medical officers appointed for the town of Belfast on the introduction of the Poor-law system into Ireland, and he continued to discharge the duties of this position until 1863, when he was elected one of the Visiting Physicians to the Belfast Royal Hospital, a post he held at the time of his death. He was Consulting Physician to the Belfast Hospital for Cutaneous Diseases and to the Belfast Consumption Hospital. He was an ex-President of the Ulster Medical Society. His private practice was extensive, and included many of the leading families of Belfast and neighbourhood.

We are indebted to a correspondent in Belfast for the following estimate of Dr. Ross's character: "It is difficult for one who was his colleague and intimate personal friend to speak of Dr. Ross as a physician and a man without either on the one hand failing to do justice to a rare personality, or on the other hand using language that may seem extravagant to those to whom the subject of this brief obituary was unknown. Dr. Ross was one of the purest, kindest, most unselfish, and most faithful men who have ever adorned the profession of medicine. His nature had no flaw of meanness or pettiness. He was absolutely devoid of jealousy or greed or unworthy ambition. He lived for his profession and his patients, and he received in return an enthusiastic affection and a profound esteem such as few men have ever evoked. No word of bitterness or censure or discontent or repining ever passed his lips. His presence brought help and comfort and benediction wherever he went. If ever man 'wore the white flower of a blameless life' it was Richard Ross. Indefatigable in labours, unwearied in well doing, careless of self, prodigal of professional aid, of wise counsel, and of kind sympathy, he has gone to his rest amidst the deepest and most unfeigned mourning. The tears of the poor are, perhaps, his best epitaph. His death leaves a sad blank in the busy life of Belfast, but his memory will long be affectionately cherished in many a home and many a heart."

Dr. ALBERT BRUNSKILL, of Liverpool, whose death at the early age of 31 we regret to have to record, was a prizeman of Trinity College, Dublin, where he graduated with honours. After serving the office of Resident Pupils in Sir Patrick Dun's Hospital he came to Liverpool in August, 1895, and undertook temporary duty at the North Dispensary, where his cousin, Dr. R. R. Brunskill, is head surgeon. Subsequently he acted as *locum tenens* in two of the Liverpool hospitals, that at Parkhill and that in Netherfield Road. Shortly after entering on residence in the latter institution he contracted typhoid fever, of which he died. The remains were removed to Dublin, and there was a large attendance of professional friends at the graveside.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently passed away are Dr. James E. Carroten, a well-known surgeon, author of a treatise on Oral Surgery, and Dean of the Philadelphia Medical College, aged 67; and Professor Hermann Seidel, Chief of the Surgical Section of the Brunswick Hospital, and for a long time assistant to Volkmann at Halle, aged 41.

NAVAL AND MILITARY MEDICAL SERVICES.

THE ASHANTI EXPEDITION.

EIGHTY-FIVE warrant officers, non-commissioned officers, and men of the Medical Staff Corps have joined the Depot Medical Staff Corps at Ashanti to form a provisional company for active service in Ashanti. This company will be under the command of Surgeon-Major Walsley, with Surgeon-Captain O'Callaghan as company officer, and Lieutenant and Quartermaster Lines as quartermaster. Orders have been received to arm this company, the warrant officers and non-commissioned officers with the revolver, and the rank and file with the Martini-Henri carbine. An advance party leaves England on November 23rd.

Further medical arrangements provide for the nursing of sick. Mrs. T. A. Gray, Acting Superintendent of Nurses, and a dame of the Royal Red Cross, has been ordered to embark. She will be accompanied by nursing sisters for work in hospitals.

Large stores of medical comforts are to be accumulated at Accra, which will be a base. The provision of means of transporting sick and wounded from the moving columns down the country to the hospitals by hand litters or stretchers has also received attention.

The medical arrangements, both in personnel and matériel, are likely to be amply sufficient, seeing that both the Commander-in-Chief and the Director-General of the Medical Department have personal experience of active service on the West Coast.

THE NAVY.

STAFF-SURGEON ALFRED PATTERSON has been promoted to be Fleet Surgeon, October 30th. He was appointed Surgeon, March 31st, 1875, and Staff-Surgeon twelve years thereafter.

Fleet-Surgeon GEORGE KELL has been placed on the retired list from November 14th, at his own request, with the honorary rank of Deputy-Inspector-General. He entered as Surgeon, March 31st, 1867, became Staff-Surgeon, September 1st, 1877, and Fleet-Surgeon, June 1st, 1895.

Surgeon JOHN DUNCAN MANNING died at the Royal Naval Hospital, Portland, on November 14th, at the age of 41.

The following appointments have been made at the Admiralty: FRANK E. BRAY, Staff-Surgeon, to the *Porpoise*, November 1st; JOHN SUTTON H. ACHESON, Surgeon, to the *Cape of Good Hope* Hospital, November 1st; FRANCIS H. A. CLAYTON, Surgeon, to the *St. George*, December 1st; FRANK H. BAYDEN, Surgeon, to the *Porpoise*, November 1st.

NAVAL MEDICAL SERVICE.

THE undermentioned gentlemen, who completed on November 4th and following days at Examination Hall, Victoria Embankment, for appointment as Surgeon in the Royal Navy, have been granted commissions:

	Marks.		Marks.

INDIAN MEDICAL SERVICE.

BRIGADE-SURGEON-LIEUTENANT-COLONEL G. HUGHESON, M.D., Medical Director-General, is granted the temporary rank of Surgeon-General from September 23rd, while acting as Inspector-General of Civil Hospitals, North-West Provinces and Oudh.

Surgeon-Lieutenant-Colonel P. A. SMITH, Bengal Establishment, has retired from the service, October 1st. His last appointment dates from October 1st, 1895, and he held Surgeon-Lieutenant-Colonel

from January 12th, 1884. He was with the Burmese expedition in 1886-87, and has the Frontier medal with two clasps.

Surgeon-Captain F. E. SWINSON is appointed Personal Assistant to the Principal Medical Officer Bombay command.

ARMY MEDICAL STAFF.

Surgeon-Colonel J. B. HAMILTON, M.D. is promoted to be Surgeon-Major-General, vice R. Lower, retired, October 3rd. Surgeon-Major-General Hamilton entered the Service as Assistant Surgeon, January 1884, and became Surgeon, March 1st, 1887; Surgeon-Major, April 1st, 1891; Brigade-Surgeon, March 25th, 1894; and Surgeon-Colonel, November 25th, 1894. He served in the Sudan campaign in 1895 as Field Director of the Lines of Communication under Brigadier-General Ewart, and was present at the destruction of Tawal Medel with clasp, and Khedive's breast clasp, and during the expedition to Burma in 1895 in medical charge of the hospital ship *Thames*. Surgeon-Major-General Hamilton has been appointed Principal Medical Officer at Liverpool, in place of Surgeon-Colonel J. H. Hughes, M.D., transferred to Chester.

Brigade-Surgeon Lieutenant-Colonel **JOHN MATTHEW, F.R.C.S.I.** is promoted to be Surgeon-Colonel, vice J. B. Hamilton, M.D., October 3rd. Surgeon-Colonel Matthew's previous commissions are dated as follows: Assistant Surgeon, September 22nd, 1884; Surgeon, March 1st, 1887; Surgeon-Major, September 25th, 1890; and Brigade-Surgeon Lieutenant-Colonel, September 11th, 1894. He was in the Ashanti war in 1873-74, receiving the medal.

Brigade-Surgeon Lieutenant-Colonel **CHARLES WHITE** is placed on retired pay, November 1th. His commissions are thus dated: Assistant-Surgeon, March 31st, 1885; Surgeon, March 1st, 1887; Surgeon-Major, March 31st, 1891; and Brigade-Surgeon Lieutenant-Colonel, September 11th, 1894.

Surgeon-Lieutenant-Colonel **G. D. LEAKE** is promoted to be Brigade-Surgeon-Lieutenant-Colonel, vice J. Matthew, October 3rd. Brigade-Surgeon-Lieutenant-Colonel Leake dates as Assistant Surgeon from April 1st, 1871; as Surgeon from March 1st, 1873; as Surgeon-Major from April 1st, 1881; and as Surgeon-Lieutenant-Colonel from April 1st, 1891. He was in the Zulu war in 1879 (medal), and with the Burmese expedition in 1895 (medal with clasp).

Surgeon-Lieutenant-Colonel **J. R. GABBETT** is promoted to be Brigade-Surgeon-Lieutenant-Colonel, vice H. W. A. Macdonald, D.S.O., retired, October 3rd. Brigade-Surgeon Lieutenant-Colonel Gabbett's previous commissions are contemporaneous with those of Brigade-Surgeon-Lieutenant-Colonel Leake.

Surgeon-Colonel **T. MAUNSELL** is directed to officiate as Principal Medical Officer, Bengal Command, vice Surgeon-Major-General T. Walsh, who has been granted leave.

ARMY MEDICAL RESERVE.

The Christian name of Surgeon-Captain **STEWARTSON CLARKE, M.D.**, is as now described, and not as stated in the *Gazette* of November 1st.

THE YEOMANRY AND RIFLE VOLUNTEERS.

Surgeon-Captain G. B. T. PHILLIPS, Pembroke Yeomanry, is promoted to be Surgeon-Major, November 20th.

Mr. GEORGE MARTIN is appointed Surgeon-Lieutenant in the 1st Cumberland Artillery, November 20th.

The Christian name of Surgeon Captain **TODD**, 1st Durham Artillery (Western Division Royal Artillery), is **DAVID**, and not as stated in previous *Gazettes*.

Surgeon-Lieutenant **W. VERNON**, 1st Volunteer Battalion the Suffolk Regiment, has resigned his commission, November 20th.

Mr. THOMAS EDWARD LLOYD is appointed Surgeon-Lieutenant in the 4th Volunteer Battalion the South Wales Borderers, November 20th.

Surgeon-Captain **J. MARTIN**, 2nd Volunteer Battalion the Duke of Wellington's West Riding Regiment, has resigned his commission, November 20th.

The Christian names of Surgeon-Lieutenant **WARWICK**, 1st Tower Hamlets Rifles, are **FRANCIS JAMES LEWIS**, and not as stated in a previous *Gazette*.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

Lieutenant-General G. H. MONCRIEFF will present the prizes of the school at 7.30 P.M. at the Banqueting Hall, Crosby Hall, E.C., on Saturday, November 7th. Among those who have accepted the invitation of the school to be present are Brigadier-General **W. H. Gatacre, D.S.O.**, recently commanding the third brigade of the Chitral Expeditionary Force; Captain **Mr. Alfred J. Smith, R.S.**, Secretary-General of the Order of St. John of Jerusalem; and Colonel **Mr. Herbert Perrott**, Secretary of the Order. Past and present members of the school can obtain tickets for the distribution and receipt by making early application to **Mr. C. J. Downer**, Fairfield, Willesden Park, N.W.

SECRETARY TO P.M.O. INDIA.

Surgeon-Major SHARRE, 27th Punjab Infantry, has been selected as secretary during the absence of Surgeon-Major **Beaton** on furlough. Surgeon-Major Sharre has seen much service in Afghanistan, Egypt, and Bosnia.

INSPECTION BY P.M.O. INDIA.

Surgeon-Major-General A. A. GORE, P.M.O. in India, is now on a long tour of inspection throughout India. He left Simla on November 7th, and ends his inspection tour in Calcutta on January 2nd, 1896. He will visit all the principal stations in the three Presidential Army Corps Commands.

AMALGAMATION OF INDIAN MEDICAL SERVICE.

The Secretary of State for India has sanctioned the amalgamation of the three (Bengal, Madras, and Bombay) branches of the Indian Medical Service into one service under the administrative control of the Govern-

ment of India, and has also accepted a proposal that the Surgeon-General with the Government of India should be the head of the amalgamated service under the designation of Director-General of the Indian Medical Service. The amalgamation, however, will take place on much the same plan as was adopted when the Commissariat and Transport Departments of the three presidencies were amalgamated in 1889, that is to say, the officers at present in the Service will continue to be borne on three separate lists, so as to avoid all cause for dissatisfaction or complaint on their part with regard to their eligibility for certain appointments and for promotion to the administrative grades of their own presidency; but the future members will be borne on one list, and will be available for employment in any part of India. It now remains for the Indian Government to fix a prospective date from which all appointments will be made on one general list.

The amalgamation was, it is generally supposed, suggested by the late Surgeon-General with the Government of India on the ground that by it the department might be reduced. The Government will certainly not fail to take advantage of the Surgeon-General's suggestion, so that reduction may be safely calculated on.

P.M.O. NORTH-EASTERN DISTRICT.

Surgeon-Colonel W. D. WILSON, on return from India, tour expired, proceeds to York (headquarters) as P.M.O. succeeding Surgeon-Colonel **Manham**, proceeded to the Cape vice Surgeon-Major-General Hamilton.

MEDICO-LEGAL AND MEDICO-ETHICAL.

MEDICAL ADVERTISING.

OUR readers will remember that we commented recently upon an advertisement which had appeared in various London newspapers, in which a "West-End Physician" offered his services at reduced fees to the public. We have made inquiries into the matter through the Medical Defence Union, and we regret to state that, contrary to our anticipation, the advertiser was a duly qualified medical man. We are glad, however, to be able to report that the advertisements will not appear again, and that the gross offence against medical ethics will not be repeated. The advertiser has expressed his sincere contrition and will "sin no more."

CORONERS' JURIES.

THE efforts to obtain the amendment of the law relating to coroners' inquests still proceed, but meanwhile some practical suggestions have been formulated by the Public Control Committee of the London Council which should do a little to render the service of jurors less irksome and arduous. The London coroners are now requested to arrange as far as is practicable for the summoning of jurors strictly by *rate*, to reduce as far as possible the number of jurors summoned for each inquest, and to arrange that where a juror complains and can show that he has been summoned more than once in two years, he shall be exempted from subsequent service for three years.

SPECIALISTS AND ETIQUETTE.

WYKEHAMIST writes: A patient under my care for many years for rheumatism, having developed an attack of psoriasis, desired to consult a specialist in skin disease. I accordingly sent her with my card to Mr. A., who is on the senior staff of the nearest skin hospital. He upon discovering her rheumatic and cardiac ailments, without any reference to me, took her to a neighbouring physician, to whom he represents the case as his own. I heard of this quite by accident, and on applying to the physician for an explanation he told me that he had no knowledge of me in connection with the case, but supposed that the lady had been under the care of Mr. A. during the whole of her history. As I have never met Mr. A. I have not written to him, but prefer to ask your opinion.

"A." When sending a patient to a consultant for a second opinion it is better, especially when the practitioners are personally unacquainted, that the general practitioner should write a note instead of merely handing to the patient his address card as a medium of introduction, as in the above case. In reference to this a doubt arises in our mind as to whether it was *de facto* presented to A., a very material point, on which depends the ethical correctness of his (A.'s) procedure. Assuming, however, that he duly received it, his action in taking the lady to a neighbouring physician was reprehensible, and contrary to traditional and modern consultative practice. Our correspondent should have addressed to him, and not to the physician specially referred to, a courteous letter of remonstrance.

MEDICAL ETIQUETTE.

H. M. R.—A dispassionate review of our correspondent's letter and Dr. W.'s courteously suggestive note, inclines us to the opinion that, although the latter should have acted in accordance with the principle laid down in the rule appended before visiting the patient referred to, he unwittingly omitted to do so either from a more or less inexcusable ignorance thereof, or inadvertence arising from the stress and worry of an extensive general practice, and not from intentional disregard of the rule. Be that as it may, "H. M. R." would in our opinion, have acted wisely in acknowledging Dr. W.'s friendly explanatory letter, and soliciting his attention to the rule in question: "When, moreover (an oft-recurring incident), an employer or other person becomes anxious and apprehensive in regard to the illness of an employee, or in the case of an impending action for damages, and the like, and for his persons

in Sunderland. The 107 deaths from diphtheria in the thirty-three towns included 61 in London, 8 in West Ham, 5 each in Wolverhampton, Birmingham, and Liverpool, and 4 each in Manchester, Salford, and Newcastle-upon-Tyne. One fatal case of small-pox was registered in West Ham, but not one in London or in any other of the thirty-three large towns. The number of small-pox patients under treatment in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital, which had been 114, 101, and 74 at the end of the three preceding weeks, had risen again to 80 on Saturday last, November 16th; 33 new cases were admitted during the week, against 12, 20, and 14 in the three preceding weeks. There were 2,645 scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last, against 2,803, 2,841 and 2,847 at the end of the three preceding weeks; 202 new cases were admitted during the week, against 206, 215, and 249 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

During the week ending Saturday last, November 16th, 521 births and 40 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had increased from 18.9 to 21.4 per 1,000 in the three preceding weeks, declined again to 18.5 last week, and was 0.8 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 14.2 in Leith to 29.8 in Greenock. The zymotic death-rates in these towns averaged 1.2 per 1,000, the highest rates being recorded in Greenock and Perth. The 74 deaths registered in Glasgow included 1 from small-pox, 14 from whooping-cough, 3 from scarlet fever, and 3 from diphtheria. Three fatal cases of scarlet fever were recorded in Edinburgh.

MEASLES V. SMALL-POX, FEVER INTERVENING.

A CASE of no small obscurity, and, as far as we can make out, one of no small importance, has been decided by Sheriff Guthrie at Glasgow. The obscurity is in the reports from the *North British Daily Mail* and other papers which have reached us, and which agree in most points, including the omission of certain details essential to any clear understanding of the case. The published particulars were reported in the *BRITISH MEDICAL JOURNAL* of November 16th, p. 1207, and amount to this: That a patient under treatment by one medical man for measles was reported to the sanitary authority by another medical man (not called in to attend him) as suffering from small-pox, and thereupon removed to "the small-pox" and fever ward" to a small-pox hospital, and subsequently deceased. There ought to be no such thing as a small-pox and fever ward, but this implied reflection upon the authorities is perhaps due to a flight of imagination on the part of the reporter. A letter from the "defender" (Dr. Stewart) to the *Glasgow Herald* clears up much of the mystery which had been imported into the case. It seems that Dr. Stewart was called in after the retirement of the practitioner first in attendance. He diagnosed typhus, and wrote to the acting medical officer of health, who took the view that it was malignant small-pox, and had the patient removed to the hospital. The next day the diagnosis of typhus was confirmed and the patient was placed in the fever ward. This explanation seems to exonerate the ambulance and supplies abundant reason for the dismissal of the action, but how the patient of many diagnoses came to be so ill-advised as to commence proceedings against Dr. Stewart remains to be explained.

A MEDICAL OFFICER OF HEALTH FOR CHESHIRE.

At the last quarterly meeting of the Cheshire County Council it was resolved, after some discussion, to appoint Dr. Vacher, of Birkenhead, medical officer of health for the county at a salary of £800 per annum. Dr. Godson, in opposing the motion, said there was no necessity to make the appointment, as the work of medical officer was already efficiently performed by the district medical officers, and that an appointment like that suggested would lead to cause friction between the local and the central medical authorities. He did not think the council should assume an air of superiority towards the district authorities, or sanction what seemed like a proposition to authorise an official to go all over the district, remonstrating, and make a disturbance wherever he could. In the end the resolution was adopted by 28 to 20.

AIRIAL DISSEMINATION OF SMALL-POX.

J. H. T.—The subject of hospital spread small-pox is very fully treated by Mr. W. H. Power, of the medical department of the Local Government Board, in the report on the *Cause and Influence of Hospital or Institution Diseases* issued from that department in 1892, and since reprinted. The hospital dealt with was the Western Hospital of the Metropolitan Asylums Board at Fulham; the story was carried on in the annual reports of the medical officer for 1894 and 1895. As regards the metropolis generally, three years later the same writer presented a summary statement of much interest. Dr. Priestley made a valuable report to the Town Council of Lancaster in regard to the year 1891; and Dr. Niven has written papers of interest on the subject in recent years, and reference might be made to those gentlemen at Lancaster and Manchester respectively, where they are now health officers. Another official report bearing on the matter is that by Dr. Bruce Low, issued by the Local Government Board, on small-pox at and near Hastings, and, presumably, we believe, from Messrs. Eyre and Spottiswoode, East Harding Street, London.

INDIA AND THE COLONIES.

MAURITIUS.

QUARANTINE.—It is not creditable to our character for intelligence and consistency, or calculated to inspire other people with a belief in our sincerity, that quarantine of the crudest and most antiquated type should be still maintained in Crown Colonies, the administration of which is controlled by the Home Government, and which do not enjoy the legisla-

tive independence of our American and Australian dependencies. We have often had occasion to complain of the detention of cholera-susceptible vessels in the stagnant, limited harbour of Malta, forced close along shore, and discharging the excrements of the sick into the foul water of the port, and we now have before us a letter from a surgeon in the *British India Steam Navigation Company* complaining of the stupidity and abuses of the system as carried out in Saint Paul, which, though possessing some semblance of local government, is none the less a Crown colony. The medical officer is, he says, not allowed to inspect a ship until the Board of Health have met and decided on the course of action. Meanwhile no communication with the shore is permitted, and several days may elapse before even medical aid can be obtained. On one occasion a man died in port without having been seen by a medical man, though there was no intention to disembark on board; and on another a seaman with a fractured skull remained twelve hours without medical aid. The inconsistency and want of uniformity in the treatment of vessels arriving from cholera-infected ports in India and elsewhere, though no cases may have occurred during the three weeks' voyage, is suggestive of corruption of some kind, and it is but a natural result of the system that, with a view of evading the regulations, fraudulent concealment of actual disease should be sometimes practised by the captains. Thus about four years ago the concealment of a case of small-pox led to an epidemic in the island, which entailed a heavy expense on the community. The health of the colony is not good, but the deaths exceed the births, the death rate of the towns varies from 40 to 70 per 1,000, 63 per cent. of the deaths being those of children under 5, and that of St. Louis, the capital, with 60,000 inhabitants, has, during the last six years averaged 40 per 1,000, as against 28 per 1,000 for the same period in Calcutta, with its population of little under a million, though its site and surroundings are by no means so favourable by nature. Nor is this high mortality confined to the denser populations of the town, for the death rate of the entire island is generally over 40 per 1,000, a figure probably unapproached by that of any similar civilised and European or semi-European people.

HOSPITAL AND DISPENSARY MANAGEMENT.

THE SIXTH ANNUAL REPORT OF THE ASYLUMS COMMITTEE OF THE LONDON COUNTY COUNCIL.

THE general work of the year at the five large institutions under the control of the Council has been efficiently carried out unmarked by any event of importance, but the steady increase of insane persons in the county area still continues, so that the number at the end of the year was 18,541 lunatics chargeable to parishes and unions within the county, as compared with 18,041 at the end of the previous year, showing an increase of exactly 500. Taking the result of the five years' work 1890 to 1895, the Committee think this rate of increase indicates the correctness of their estimate given in their last report, and that without some permanent change occurs in the conditions which have prevailed since 1880, this estimated number must now, at the ascertained rate of progression, be taken to stand at an increase of about 600 lunatics per annum.

Although one huge asylum after another has been provided, and a sixth one will be immediately commenced at a cost of £250,000 (exclusive of site and equipment) on January 1st of this year, there was a deficit of beds amounting to 1,317, after allowing for the 600 beds at Barning Heath held by agreement, so that the population of the new asylum is practically already provided, and if the County Council hope to bring their accommodation up to a level with their requirements they will not only have to erect two asylums instead of the one they contemplate, but have a third one well in hand before the first two are completed. This would entail an expenditure of one million sterling, exclusive of the cost of sites and equipment, a truly formidable programme. The Committee fully recognise the gravity of the question; they say in their report: "The deficiency of accommodation is still a most serious question; every bed is occupied, and the only vacancies available are those caused by deaths or discharges." There are 1,104 patients boarded out in different asylums throughout the county, for whom the rate-payers are paying at the rate of 12s. 6d. to 14s. per head per week, while the cost of maintenance in the asylums belonging to the county is 10s.

The boarding-out of insane persons from their homes and friends inflicts great hardships upon them, and nothing short of the gravest necessity should justify it. Yet contracts are contemplated for the reception of patients as far off as Dorchester and Plymouth. The seriousness of the position is enhanced by the fact that there is little hope of materially increasing the number of patients boarded out in consequence of lack of room throughout the country. The appointment of a pathologist was stated to be under consideration when the report was published. Happily, the appointment has since been made, and the Committee have been fortunate in securing the services of Dr. F. W. Mott, whose work in neuropathology is so well known.

Facilities have been afforded for the clinical teaching of mental diseases, and several of the London hospital medical schools have taken advantage of the offer of the Committee.

The total number of cases under treatment during the year was 12,176; 3,192 were admitted and 2,818 were discharged or died. The percentage of recoveries calculated upon the number admitted was 42.66, and the death-rate calculated upon the average number resident was 2.44 per cent.

There is an important point to be observed in connection with the recovery rate, and it is this: Under the London County Council there are five of the largest hospitals for the insane in the kingdom, and that for the last ten years the recovery rate in these asylums, including transfers, has been over 51 per cent., calculated on the admissions; and during the last year, excluding transfers, it was 41.61 per cent., a result which compares very favourably with other and smaller institutions.

MEDICAL MAGISTRATE.—Dr. Arthur Flint, of Westgate-on-Sea, J.P. for the Cinque Ports, has been placed on the Commission of the Peace for the County of Kent on the nomination of Earl Stanhope, Lord Lieutenant.

MEDICAL NEWS.

THE treasurer of Guy's Hospital has received a cheque for £1,000 from Mr. A. L. Cohen for the endowment of a bed in memory of his late son, H. A. Cohen.

THE annual dinner of the Harvelan Society of London will be held at the Café Monico on Thursday, November 28th, the president, Sir John Williams, Bart., in the chair.

MR. WILLIAM McVEAN of Brixton, who died on September 29th, has bequeathed £500 to the Evelina Hospital for Sick Children, Southwark Bridge Road.

SCARLET FEVER IN EDINBURGH.—It was reported at the meeting of the Edinburgh Town Council on November 19th that there were on that day 449 patients in the City Hospital, of which 104 were adults, and 345 children. Of these there were 384 cases of scarlet fever, and 39 of typhoid fever. Yet it is maintained by some that there is no epidemic of scarlet fever in Edinburgh.

THE Committee of the Conjoint Laboratories of the Royal Colleges of Physicians and Surgeons in London have made a grant of £100 out of the Goldsmiths' Company's grant to Dr. Cartwright Wood for investigations as to improved means of treating horses with a view to obtaining diphtheria antitoxic serum in a shorter time than is possible by the methods hitherto in use.

THE METRIC SYSTEM.—In replying to a deputation representing Chambers of Commerce, which waited on him on November 20th, Mr. Balfour, the First Lord of the Treasury, assented to the propositions that the metrical system of weights and measures should be legalised for all purposes, and that it should be taught in elementary schools, but expressed the opinion that it would be impracticable to attempt to render it, within the suggested period of two years, the only legal system.

THE Medical-Psychological Association of Great Britain and Ireland will hold an examination for its certificate in Psychological Medicine in London, Edinburgh, Glasgow, Aberdeen, and Dublin on Thursday, December 19th. Intending candidates are required to give fourteen days' notice to the Registrar, Dr. Spence Burnwood Asylum, Lichfield, from whom further information can be obtained. Essays for the bronze medal and prize given by the Association must be received not later than May 30th, 1894.

THE CHOLERA.—The *Times* correspondent in St. Petersburg telegraphed on November 18th that the *Official Gazette* of that date states that cholera has reappeared in St. Petersburg. It refers to isolated cases with all the symptoms of cholera. Besides 27 seizures and 12 deaths down to November 6th, there have since been 38 more cases, of which 19 have proved fatal.—Up to November 16th the total number of deaths from cholera in Egypt were 795 and 620 deaths. All these, however, were confined to the district of Damietta and Lake Menzaleh. The health in all the big towns, such as Alexandria, Cairo, and Tanta, is reported to be excellent.

CITY OF DUBLIN HOSPITAL.—For the vacancy created by the retirement of Dr. H. Fitzgibbon from the surgery of this hospital there are several candidates—namely, Mr. F. Nixon, surgeon to the Mercer's Hospital; Mr. J. D. Pratt, surgeon to Jarvis Street Hospital; Dr. Boyce; Mr. Jameson Johnson, assistant surgeon to the Richmond Hospital; Mr. Gordon, assistant surgeon to the Adelaide Hospital; and Mr. W. J. Thompson, demonstrator of anatomy in the College of Surgeons. Dr. C. B. Hall was also a candidate, but since his election as Regius Professor of Surgery in the University of Dublin he has withdrawn his name.

EDINBURGH ROYAL MEDICAL SOCIETY.—The following gentlemen have been elected office bearers: *Presidents*: J. E. Bowen, M.B., C.M.; W. M. Taylor, M.B.; C. M. Kenneth Maclean, M.B., C.M. *Secretaries*: J. Brunton Elakie, Scott Carmichael, M.B., C.M. *Chairman of Finance Committee*: Edwin Bramwell. *Curator of Library*: Harry Fowler. *Curator of Museum*: T. Anderson. *Chairman of Public Business Committee*: W. T. Ritchie. *Editor of Transactions*: W. A. G. Alexander, M.B., C.M. *Treasurer*: J. R. Young. *Subsidiaries*: A. P. Ormiston.

MEDICAL VACANCIES.

The following vacancies are announced:

BATH GENERAL OR ROYAL MINERAL WATER HOSPITAL.—Resident Medical Officer; unmarried. Salary, £100 per annum, with board and apartments in the hospital. Applications to Frederick W. Dingle, Registrar and Secretary, before November 28th.

BLACKBURN AND EAST LANCASHIRE INFIRMARY.—Junior House-Surgeon. Salary, £100 per annum, with board, washing, fuel, etc. Applications to Nelson A. Wood, Secretary, Secretary Office, 7, Richmond Terrace, Blackburn, by November 12th.

BRADFORD INFIRMARY.—Resident Surgeon; duly qualified; unmarried. Salary, £100 per annum, with board and residence. Applications, endorsed "Desperately Sought," to William Maw, Secretary, by November 12th.

CENTRAL LONDON OPHTHALMIC HOSPITAL, 23A, Gray's Inn Road, W.C.—House-Surgeon. Rooms, coals, and light. Applications to the Secretary by December 1st.

CITY OF LIVERPOOL.—Assistant to the Medical Officer of Health, fully qualified, graduate of a British University, and possess diploma in Sanitary Science or Public Health. Salary, £350 per annum, subject to a contribution of 25 per cent. to the Corporation Superannuation Fund. Not more than 35 years of age. Applications endorsed "Assistant to the Medical Officer of Health" to be sent to the Town Clerk, Municipal Offices, Liverpool, to be delivered by November 30th.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House-Physician. Appointment for six months. Board and Residence provided and salary at the rate of £30 per annum. Applications to the Secretary by December 12th.

COUNTY BOROUGH OF BOLTON.—Medical Officer and Public Analyst, doubly qualified. Salary, £250 per annum. Applications to R. G. Hinnell, Town Clerk, Town Hall, Bolton, by December 1st.

DENBIGHSHIRE INFIRMARY, Denbigh.—House-Surgeon; must be duly qualified to practise medicine and surgery, and be conversant with the Welsh language. Salary, £50 per annum, with board, residence, and washing. Applications and testimonials to W. Vaughan Jones, Secretary, by December 2nd.

ENNIS DISTRICT LUNATIC ASYLUM.—Assistant Medical Officer, doubly qualified, unmarried, and not more than 35 years of age. Salary, £100 per annum, with furnished apartments, fuel, washing, fuel, light, and attendance. Applications to Dr. Gilman, Resident Medical Superintendent, by December 12th.

GENERAL HOSPITAL, Birmingham.—Assistant House-Surgeon. Appointment for six months. No salary, but residence, board, and washing provided. Applications to Howard J. Collins, House Governor, by November 30th.

GENERAL INFIRMARY AT GLOUCESTER AND THE GLOUCESTERSHIRE EYE INSTITUTION.—House-Surgeon; doubly qualified. Salary, £100 per annum, with board, residence, and washing. The Assistant House-Surgeon is a candidate for the post, and, if elected, the office of Assistant House-Surgeon will be vacant. Candidates must be doubly qualified. Board, residence, and washing provided. Applications to the Secretary by November 30th.

GLASGOW EYE INFIRMARY.—Resident Assistant House-Surgeon. Salary £50 per annum, with apartments and board. Applications to William George Black, Secretary, 23, West Regent Street, Glasgow, by December 10th.

HOSPITAL FOR DISEASES OF THE THROAT, Golden Square, W.—Resident Medical Officer. Salary, £50 per annum, with board, lodging, and washing. Applications to W. Holt, Secretary-Superintendent, by November 30th.

HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Manchester.—House-Surgeon to outpatients; unmarried. Appointment for six months but eligible for a permanent term. Salary, £100 per annum. Applications to the Secretary by December 1st.

HOSPITAL FOR WOMEN, Soho Square.—Assistant Medical Officer; non resident (appointment for three months) and Assistant Physician. Applications to the Secretary by November 1st.

KING'S COLLEGE, London.—Assistant Lecturer in Microbiology. Applications (from King's College Students only) to Walter Smith, Secretary, by November 30th.

LEICESTER INFIRMARY.—Honorary Ophthalmic Surgeon (Temporary). Applications to the Secretary, 14, Peter Lane, Leicester, by November 28th.

LONDON HOSPITAL, Whitechapel, E.—Dental Surgeon. Applications to the Governor by November 1st.

LONDON TEMPERANCE HOSPITAL, Hanbury Road, N.W.—Assistant Resident Medical Officer; doubly qualified. No salary, but board, washing, and residence provided. Applications to A. G. Rogers, Secretary, by December 31st.

MANCHESTER ROYAL INFIRMARY.—Assistant Medical Officer at the Moseley Fever Hospital; unmarried. Appointment for twelve months. Salary, £100 per annum, with board and residence. Applications to the Chairman of the Board, Royal Infirmary, Manchester, by November 30th.

MONKWEAR MOUTH AND SOUTHWICK HOSPITAL, Sunderland.—House-Surgeon; unmarried; doubly qualified. Salary, £100 per annum, with board, residence, and washing. Applications to J. G. Jordan, Honorary Secretary, by December 1st.

NEW HOSPITAL FOR WOMEN, 141, Finsbury Road.—Two qualified Medical Women as House-Surgeons. Applications to Margaret M. Ingster, Secretary, by November 28th.

NORTH-EASTERN HOSPITAL FOR CHILDREN, Backhouse Road, Sunderland, N.E.—House-Surgeon; doubly qualified. Appointment for six months; at the expiration of this term he will be required if eligible, to serve as House-Surgeon for a further period of six months.

as House-Physician at the rate of £50, and as House-Surgeon at the rate of £30 per annum. Junior House-Physician for six months, salary, £20. No salary, but board and lodging, including washing, provided. Applications to the Secretary, 27, Clement's Lane, E.C., by December 5th.

ROYAL ALBERT HOSPITAL, Reading.—House-Surgeon and House-Physician. Salary £100 per annum, with board, lodging, and washing. Also Assistant Medical Officer, with board, lodging, and washing provided, but not salary. Appointments for six months. Applications to the Secretary before December 5th.

ROYAL WESTMINSTER OPHTHALMIC HOSPITAL, King William Street, West Strand, W.C.—Clinical Assistants. Applications to T. Beattie Campbell, Secretary, by November 25th.

ST. GEORGE'S AND ST. JAMES'S DISPENSARY, 60, King Street, Regent Street, W.—Assistant Medical Officer, £100 per annum, with board, lodging, and washing. Also Physician. Applications to the Secretary, St. Leger Bunnett, by December 4th.

ECARBOROUGH HOSPITAL AND DISPENSARY.—Assistant House-Surgeon. Appointment for six months. Salary, £50 per annum, with board and lodging. Stimulants and washing not provided. Applications to the Honorary Secretary by November 25th.

SWANSEA GENERAL HOSPITAL.—House-Surgeon. Salary, £80 per annum, with board, residence, washing, and attendance. Applications to Jno. W. Morris, Secretary, 9, Castle Street, Swansea, by December 5th.

TIVERTON INFIRMARY AND DISPENSARY.—House-Surgeon and Dispenser; registered and unmarried. Salary, £105 per annum, with lodgings, attendance, fire, and lights. Applications to Arthur Fisher, Honorary Secretary, by November 25th.

VICTORIA UNIVERSITY, Manchester.—External Examiner in Pharmacology and Therapeutics and in Surgery. Appointment for three years. Applications to Alfred T. Bentley, Registrar, by November 10th.

WARNEFORD HOSPITAL, Leamington.—House-Surgeon. Salary, £100, with board, lodging, and washing. Appointment for six months subject to re-election. Applications to the Secretary before December 5th.

WESTMINSTER GENERAL DISPENSARY, Gerrard Street, Soho, W.—Honorary Surgeon. Applications to the Secretary by November 25th.

MEDICAL APPOINTMENTS.

ABRAHAM, Phineas S., M.A., M.D., B.Sc., F.R.C.S.I., appointed Assistant Surgeon to the Hospital for Diseases of the Skin, Blackfriars.

ADAMS, F. E., M.D., B.U.I., D.P.H.Camb., appointed Medical Officer of Health to the Hereford County Council.

BARBER, George Walter, M.R.C.S.Eng., L.R.C.P.Lond., appointed Medical Officer to the Kalgoorlie (Hannan's) Hospital, West Australia.

BROSTER, Arthur E., L.R.C.P.Edin., M.R.C.S.Eng., appointed Medical Officer to the Small-pox Hospital of the Warrickworth District Council.

CARLYON, F. H., M.B., C.M. Edin., appointed Medical Officer to the Royal Cornwall Infirmary, Truro.

CLARKE, T. H. M., B.A., M.B., B.Ch., B.A.O. Dub. Univ., appointed Senior Resident Surgeon to the Jervis Street Hospital, Dublin.

DAVIES, Albert Barnes, M.R.C.S.Eng., L.R.C.P.Lond., appointed Honorary Surgeon to the Stroud General Hospital.

DUNCAN, Robert Bruce, M.D., B.S.B. Hy. Dundelm., appointed Medical Officer for the Bradninch District of the Tiverton Union.

HARDWICK, E. W., B.A.Camb., M.B., B.C., appointed Medical Officer of Health to the Quarry Bank Urban District Council.

HARDY, C. M., M.B. Durh., B.S., appointed Medical Officer of Health for the Darlington Rural Sanitary District.

HARRIS, H., L.R.C.P.Edin., M.R.C.S.Eng., appointed Medical Officer for the Bascup District of the Haslingden Union.

KEMP, Benjamin, M.R.C.S.Eng. L.S.A., reappointed Medical Officer of Health to the Horbury Urban District Council.

LITTLE, E. O. Gordon, M.D.Lond., B.A.Cape Univ., M.R.C.P.Lond., M.R.C.S.Eng., appointed Assistant Physician to the East London Hospital for Children, Shadwell.

MCGACHEN, P. W. D., L.F.P.S. Camb., L.S.A., D.P.H.Eng., appointed Medical Officer for the Markyate District of the Luton Union.

MACINTOSH, O. J., M.B., C.M. Edin., appointed Medical Officer and Public Vaccinator for the Parish of Portpatrick.

MILLER, W. Francis, L.D.S.R.C.S.Eng., appointed Honorary Dental Surgeon to the Thames Ditton Cottage Hospital.

MATTHEWS, Mr. T. G., appointed Medical Officer for the Sixth District of the Mansfield Union, *viz.* W. A. Stamford.

MOORE, T., M.R.C.S.Eng., L.S.A., appointed Medical Officer for the Hazelgrove, etc., District of the Stockport Rural District Council.

NUTTINO, E. S., M.B., C.M. Edin., appointed Medical Officer of Health to the Warsop Urban District Council.

PACKER, Harry D., M.R.C.S.Eng., L.R.C.P.Lond., appointed Assistant Resident Medical Officer to the East Riding Lunatic Asylum, Beverley, Yorkshire.

ROWAN, John, M.B., C.M., appointed Assistant Ophthalmic Surgeon to the Glasgow Ophthalmic Institution, Glasgow Royal Infirmary.

SHARP, E., M.R.C.P.Eng., L.S.A., appointed Physician, Consulting Medical Officer to the Royal Cornwall Infirmary, Truro.

SHARP, Hugh C. B.A., M.R.Camb., appointed Honorary Medical Officer to the Royal Cornwall Infirmary, Truro.

SPENCER, Edward, M.B., Ch.B. Vict., L.S.A., appointed Resident Medical Officer to the Colonial Hospital, Perth, Western Australia, *viz.* William Elgee, resigned.

THOMAS, Mr. D., appointed Medical Officer of Health to the Ystradgynlais Rural Sanitary Council.

TATNEMAN, E. M., L.R.C.P., L.R.C.P.S., appointed Medical Officer for the Fourth District of the Parish of St. George's-in-the-Bush.

TINDALL, Alex. M., M.R.C.S.Eng., L.S.A., appointed Medical Officer for the No. 3 District of the Market Harborough Union.

TUXFORD, Arthur, M.D., appointed Medical Officer of Health to the London Town Council, the Port of London Authority, and the London Rural Sanitary Council, *viz.* Mr. W. C. C. P. P. P.

WATSON, J. K., M.D., C.M. Edin., appointed House-Surgeon to the Essex and Colchester Hospital.

LEANDREW, G. H., M.R.C.S., L.R.C.P., appointed Assistant House-Physician to King's College Hospital.

BRIDGER, H. A., M.R.C.S., L.R.C.P., appointed House-Accoucheur to King's College Hospital.

PLAYFAIR, E., M.B.Lond., M.R.C.S., L.R.C.P., appointed Assistant House-Accoucheur to King's College Hospital.

BODEN, J. S., M.R.C.S., L.R.C.P., appointed House-Surgeon to King's College Hospital.

TROUP, J. McD., M.A., L.S.A., appointed House-Surgeon to King's College Hospital.

THOM, P. C. E., M.R.C.S., L.R.C.P., appointed House-Surgeon to King's College Hospital.

DIARY FOR NEXT WEEK.

MONDAY.

LONDON POST-GRADUATE COURSE, London Throat Hospital, Great Portland Street, 8 P.M.—Dr. Edward Woakes: Tinnitus and Vertigo.

MEDICAL SOCIETY OF LONDON, 830 P.M.—Mr. Edmund Owen: The Operative Treatment of Clot Pelate. Dr. G. E. Beover: The Distribution of Motor and Sensory Symptoms after Injury to the Brachial Plexus.

TUESDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 3 P.M.—Dr. Craig: Insanity with Cardiac Disease, Phthisis, Gout, etc.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 2 P.M. Lectures at 4.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 20, Hanover Square, W., 8.30 P.M.—Discussion on the Possibilities as to the Latency of Parasitic Germs or Specific Poisons in Animal Tissues, as in Hydrophobia, Erysipelas, Syphilis, Leprosy, Ringworm, Tuberculosis, etc., in which Mr. Jonathan Hutchinson, Dr. Washburn, Dr. J. Kingston Fowler, Dr. Phineas Abraham, and Mr. J. Ernest Lane will take part.

WEDNESDAY.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. J. Mitchell Bruce: On Asthma.

WEST LONDON HOSPITAL, Hammermith, W., 5 P.M.—Mr. Chestle: Surgical Cases (Post-Graduate Course).

HUNTERIAN SOCIETY, 830 P.M.—Dr. G. E. Herman: Vaginismus and Allied Affections. Dr. Arnold Chaplin: The Effect of Physiological Rest upon the Lung in Phthisis.

THURSDAY.

LONDON POST-GRADUATE COURSE, Hospital for the Paralyzed and Epileptic, Queen Square, 2 P.M.—Mr. Victor Horsley: Surgery of the Nervous System. Hospital for Sick Children, Great Ormond Street, 4.30 P.M.—The Surgical Registrar: Pathological Demonstration. Central London Sick Asylum, Cleveland Street, 5.30 P.M.—Mr. John Hopkins: Cases in the Wards.

FRIDAY.

LONDON POST-GRADUATE COURSE, Bacteriological Laboratory, King's College, 3 to 5 P.M.—Professor Crookshank: Lecture: Tetanus, Typhoid, and Cholera. Practical Work: Examination of Comma Bacilli, Chemical, and other Tests.

SATURDAY.

LONDON POST-GRADUATE COURSE, Bethlem Royal Hospital, 11 A.M.—Dr. Craig: Lunacy Law.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 3s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTHS.

SANKEY.—On November 16th, at Boreatton Park, Baschurch, the wife of E. H. O. Sankey, M.A., M.B., B.O., of a daughter.

WIGAN.—November 16th, at Portishead, Somerset, the wife of Charles A. Wigan, M.D., of a daughter.

MARRIAGE.

MUDD—PRICE JONES.—On November 16th, at St. Mark's, Surbiton, by the Ven. Archdeacon Barnard Barrington, William Mudd, M.B., B.S., son of Barrington Richard Mudd, M.R.C.S., late of Storrington, Sussex, to Evelyn, daughter of the late Wm. Price Jones, M.D., of Surbiton, and of Mrs. Price Jones, Farleigh House, Kingston-on-Thames.

available lines of the principal, and at such a time it is not commendable for an assistant to try to make the himself out of an employer's pocket. I suppose, rather than pay an assistant some (small) fee in addition to his salary, a principal would prefer to engage a second assistant to carry on his practice in conjunction with him. The object is what appears to be consistent with the ethics of the case, but it must not be forgotten that, from a legal point of view, any correspondence between a principal and an assistant, or any correspondence at all, is a breach of the law. The law might decide he has no claim for increased remuneration at all. A solicitor is the only person to advise him here.

PROVIDENT DISPENSARIES

STUMP.—(1) Most provident dispensaries are compelled to formulate rules according to local requirements, but the Secretary of the National Provident Dispensary Association (Mr. C. H. Warren, 5, Lamb's Court Street, W.C.), would doubtless furnish a copy of their rules, which might be of assistance. It can not be said there is anything objectionable from a professional point of view in being connected with a provident dispensary, but it is not a very commendable thing to do well to consider the matter carefully before embarking on any undertaking of this character. Such an institution, unless carefully constituted and managed, might become the ruin and at the same time the prostration of much talent to his private practice. In some instances, owing to widespread poverty of the population, institutions of this kind may be desirable, but where the public are able to pay even modest fees as private patients it is far better for the practitioner to treat them as such rather than as members of a provident dispensary, but this has been pointed out by the last of the letter are few. Where, too, a practitioner becomes medical officer to a provident dispensary it commonly happens that many of his old patients are at once induced by considerations of cheapness to join, and he is a loser to the extent they would have paid in excess annually as private patients.

RESTRICTIVE REGULATIONS OF THE ROYAL COLLEGE OF PHYSICIANS.

MR. D. HOOPER, B.A., M.B., M.R.C.P. Lond., Physician to the Surrey Dispensary (Private), writes: "I, 'Gibbs' will refer to the *Medical Practitioner*, p. 25, on the 'Restraint of Fees,' he will find that Fellows may be not entitled to sue; Members may and do sue, and I have myself recovered fees in the common law court. In the Charter, By-laws, and Regulations of the Royal College of Physicians of London, 1800, p. 25, Chapter XXV, on 'the duties and conduct of Fellows, Members, and Licentiate.' By-law 170 says 'no Fellow the College shall be entitled to sue for professional aid rendered by him,' but there is no such by-law as to Members. By-law 172 says 'no Fellow or Member of the College shall be engaged in trade or dispense medicines,' and 'Ethics' wants to know the grounds or reasons for this by-law. I suspect it was made to prevent consultants from interfering with the business and profits of the general practitioners (surgeons and apothecaries), who consulted them, and thus at one time always supplied their patients with medicines, and derived their income from so doing. The objection that this by-law 'debars the poor in rural districts from being attended by Members of the College,' seems to me frivolous; the poor would never call on a Member, they could not pay his fees, but they could have his services either in hospital or dispensary, and, as a rule, they would consult a Licentiate of the College. As we here to refer to by-law 171 ('Ethics not to be Assumed'), which seems to me to settle the question so long and so often discussed in your columns as to the M.D. and the title of 'Dr.' By-law 177 says 'no Fellow, Member, Extra-Licentiate, or Licentiate of the College shall assume the title of 'Dr.,' or append to his name the title of Doctor of Medicine, or the letters M.D., or any other letters indicating that he is a graduate of a University unless he has obtained a degree entitling him to do so.'

NOTES, LETTERS, Etc.

CONNECTION.—We are glad to find that Mr. W. R. Anonim, of St. Leonard's Court, near Gloucester, whose death was reported in the *BRITISH MEDICAL JOURNAL* of November 18th, is still alive and in good health, although he has resigned his public offices and retired from active business.

DR. O. H. GARLAND (Leith) writes: In the *BRITISH MEDICAL JOURNAL* of November 9th Dr. Johnston furnishes you with a short note of 'A Fatal Case of Cocaine Poisoning,' and concludes with the assertion: 'There was no post-mortem examination.' Had Dr. Johnston made a more fuller inquiry he would have found this statement to be incorrect. As a matter of fact, I was instructed by the Crown authorities to perform the post-mortem, the full particulars of which are recorded in the *Lancet* of November 2nd.

"THEY KNOW NOT THE MANNER OF THE GOD OF THE LAND."

SURGEON-LIEUTENANT COLONEL N. C. CHESTER (Cairo) writes: Surgeon-General Harty, in his letter published in the *BRITISH MEDICAL JOURNAL* of October 15th, asks me to specify the "factors" re-assertion of epidemic fever to which I alluded in my previous communication. I beg to refer him to an article written by me, published in the *Lancet* on August 2nd last.

THE D.P.H. (SCOTTISH CONJOINT BOARD).

DR. T. HARVEY THOMSON (Campbelltown, N.B.) writes: In the *BRITISH MEDICAL JOURNAL* of November 9th I notice, in a letter referring to the above diploma signed by 'A Candidate,' a statement—given as a fact—that 'a very full and complete course of special study in one of the Edinburgh laboratories is absolutely essential for success,' and that 'no one who is in practice should attempt it unless he can have at least six months for special study'—this presumably meaning in a recognized laboratory.

As one who took this diploma in May last, I am in a position to say that this picture is too dark and gloomy, and it may be encouraging to

prospective candidates to have my experience in the matter. Without any help whatever I equipped a home-made laboratory, and in the spare moments of a somewhat busy practice worked up the subject solely with the aid of the book recommended. I then went up to Edinburgh and passed both examinations, proving that laboratory work in Edinburgh or elsewhere is not absolutely essential for success, and that the examination in question may be successfully attempted by one in practice.

With 'A Candidate's' statement as to the searching nature of the examination I thoroughly concur. In the examinations held in May last only two out of eight passed, the other successful candidates besides myself belonging to the Army Medical Staff, and having had, therefore, the advantage of laboratory work at Netley.

This year's record appears to have been even worse, not one of ten candidates apparently having been awarded the diploma; but, while the examination is an extensive and searching one, this but renders the diploma all the more valuable, and does not place it beyond the reach of those in private practice, as the conclusions come to by 'A Candidate' would lead us to suppose.

REMUNERATION OF CIVILIAN MEDICAL PRACTITIONERS IN CHARGE OF TROOPS.

J. W. M. writes: In answer to 'Civil Surgeon in Charge of Troops,' whose letter appears in the *BRITISH MEDICAL JOURNAL* of November 5th, 1893, p. 1311, I would ask him, Why does he take the appointment? On his own showing, the work is laborious and responsible out of all proper proportion to the rate of pay. So long as Government can get men to take such appointments at present rates, it is useless to expect them to pay more.

A BULLOCK IN A PILLOX.

DR. GEORGE PLUMB, of the University of Chicago, has given utterance to the belief that the days of cooking and dining are drawing to a close. Soon, he declares, we shall be able to live on concentrated food tablets, which, with hot water, will be sufficient to maintain life. He affirms that the essence of 1,200 lbs. of beef can be contained in an ordinary pillbox, and that a man may ration himself for several days by carrying a case weighing but 8 ounces, and which contains 3 tablets of concentrated soup, which is equal to 8 quarts; 4 tablets of beef, equal to 6 lbs.; 1 tablet of milk, equal to 1 pint; 2 tablets of wheaten grist, equal to 2 lbs.; and 1 tablet of egg food, equal to 12 eggs. It is not surprising that this prophecy of life lived on concentrated foods should emanate from Chicago, where on one hand beef and pork are abundantly packed by the million, where, on the other, a money-pursuing population have scarcely time to eat, and where but very few have learnt the art of dining. Pepsin and beef pills are the natural outcome.

SUBACUTE RHEUMATISM CURED BY BINIODIDE OF MERCURY.

DR. C. R. ILLINGWORTH (London) writes: A lady who had suffered six years ago from rheumatic mitral valvular disease for three years, and had been cured by blisters and iodide of sodium, consulted me for sub-acute rheumatism of the right hand and fingers. The sheath of the palmar tendons was swollen up both above and below the wrist, and all the joints were swollen and very painful. I prescribed as follows: B. Sol. hydrarg. bichlorid. (1 to 1,000) 5vj, sod. salicyl. 3ss, sod. glyc. liquid. ʒss, q. ad ʒvj ʒss secundis ho. 18, and I applied soap and belladonna liniment locally. In 24 hours all the swelling, tenderness, and pain had disappeared. The mercurial group have the following actions on the economy: A derivative one, congesting internal organs and relieving peripheral ones, thus aiding in the cure of bronchitis and pneumonia, croup, and pleurisy, and exerting a marked influence on the course of all periphery-central disorders like meningitis, a congestion likewise relieving inflammations of peripheral organs, such as the skin and the joints, and finally a bactericidal one. This case was a periphery-central disorder. The cure of acute rheumatism by biniodide is quite as marked, but not I consider because, as some think, it is a germ disease.

LICENTIATES AND THE TITLE OF "DR."

DR. J. W. EASTWOOD (Dinsdale Park, near Lillingston) writes: Some years ago I had occasion to write to the Edinburgh College of Physicians about the title of 'Dr.,' and I received the following reply:

Royal College of Physicians, Edinburgh, Feb. 20, 1892.

Dear Sir,—In reply to your letter I have to say that this College has never encouraged its licentiates to assume the title of 'Dr.,' as they believe that title legally to belong only to those who hold the degree of M.D. from a university.—Yours faithfully,

J. W. Eastwood, Esq., M.D., etc.

JOHN WYLLIE.

LIVERPOOL VICTORIA LEGAL FRIENDLY SOCIETY.

A NORTHAMPTON correspondent writes enclosing as a written offer made by an agent of the above Society to a local practitioner. The Society takes adults and children at the rates of one penny and a halfpenny per week respectively, and allows its medical officers 80 per cent. of all money collected. By way of encouragement its agent issues the above practitioner the last quarterly payment to one of its medical staff was a cheque for 17s. 6d. It is satisfactory to find from a medical point of view that the success of this Society in Northampton is but moderate.

INFLUENZA versus PUBLISHING.

The Influenza fiend has found a new happy hunting ground of mischief in South Africa, and seems to be producing there the havoc so well known here. The Influenza was last winter sometimes privately pleaded to irate contributors as an excuse for editorial shortcomings, but the *Port Elizabeth Telegraph* has gone a step further, and brought out its issue of October 15th with the following public announcement: 'Owing to the havoc which Influenza has placed amongst the staff of this paper we have to crave the indulgence of our readers.' A printer's devil may do wonders in the back art, but an inexperienced editor has not yet been able to hypnotize men into that state in which he can fulfil the duties of the editor. The *Port Elizabeth Telegraph* may be recommended to Du Maurier as one by which his imagination might find a way.

THE GRANT COLLEGE MEDICAL SOCIETY, BOMBAY.

A well-informed correspondent writes: This Society includes in its rank its members the few of the indigenous medical men of Bombay. These are the men who aspire to become professors and hospital physicians and surgeons and who are acquiring and organizing with a view to developing promptly and uneconomically these members of the Indian Medical Service who are at present employed in performing civil medical and sanitary work in India and putting themselves in staid in their place. The 7 members of the Society for the year 1894 are therefore an interesting subject of study, as they offer the best possible means of gauging the scientific and professional capacity of this class and ascertaining what they are doing for the advancement of medical science and art. The Society held ten ordinary meetings during the year. In addition to these nine special meetings of the medical profession were held under the auspices of the Society for the purpose of discussing the subjects of Pasteurism and bacteriology.

Both ordinary and special meetings were well attended, and this fact attests the desire which obviously exists among the influence over the medical men of Bombay to keep themselves abreast with the rapid advances which medical science is making in these days. This is most creditable and praiseworthy; but on taking stock of the proceedings of these meetings the result is disappointing. The discussions at the ordinary meetings were mostly critical, two of them being devoted to the subject of plagues. They were diffuse, vague, and inconclusive, sometimes petty and childish. They indicate want of originality, want of grasp, and after careful perusal of them we have been unable to detect any clear accession to medical knowledge or useful contribution to medical practice. The agenda of the special meetings were not above the level of a medical students' debating society. There was plenty of talk and confused argument, but no evidence of research, and at the end the question remained exactly where it was at the beginning, the dominant feeling apparently being that because Pasteur's work was not final or infallible it was a waste of money to establish institutions in India for the purpose of testing or extending it. This debate on Pasteurism was of the same character as the similar discussion on fever which took place in 1893—verbose, superficial, and utterly unproductive. The proceedings in both cases are best described by the old Scotch proverb: "Muckle cry an' mickle 'oo, as the deil said when he clippit his soo."

THE TITLE OF PHYSICIAN.

I.F.P.S.G. writes: The letter in your issue of November 9th concerning the above is one more reminder of a question which still troubles the minds of Biontates who unfortunately find all doors barring their entrance to a M.D. degree shut as closely as ever. May I ask the writer: Would it not be better for the British Medical Association to get Colonial qualifications recognised as additional titles on the *Register*, and thus give practitioners the right to be called Doctors? Is it fair that Canadian degrees in medicine are not registrable as additional titles?

THE DACTYLOTYPE.

A CORRESPONDENT writes from Switzerland: A recent invention by a Swiss physician will do much to render life easier for his fellow countrymen. The invention is described in the *Geschichte der Berichte*, issued by C. Fr. Hansmann, of St. Gallen, and it has already been patented in most countries. The object of the instrument, which is called the *Zehenschreiber* ("to cleaner"), or dactylotype, in the words of the learned inventor, Dr. Voland, of Davos Dorf, is "to thoroughly clean the spaces between the toes of the shoe with special predilection, sucking and ready and sucking sucking dirt." After do so, the special difficulty in getting to the bottom of the spaces between the third and fifth toes. The inventor goes on to say: "Many mothers and nurses have certainly had experience of this difficulty in the care of children. They have much trouble in making the little feet really quite clean, for it is altogether too troublesome to press to the bottom of the spaces between the toes. No one to whom the careful cleanliness of the feet is a necessity will be able to do without the dactylotype on his toilet table so soon as he has once learned the convenience of the instrument. The employment of the instrument is very simple. It can be used in the standing or sitting position. You lift the foot to be cleaned across the knee of the other leg, and, with the hand opposite the foot to be cleaned, you place the toe cleaner, previously dipped in water or soap and water, between the individual toes as far as the bottom of the intertoes, and then move it to and fro several times in a saw-like manner. If you then bend the great toe towards the sole and stretch the other toes toward the back of the foot, you can easily reach also the hitherto-not-easily-accessible folds under the toes from the second to the fifth, and clean them too in the same pleasant way. For final drying a special toe-cleaner may be employed in the bath. The dactylotype is patented in most countries. It is manufactured by C. Fr. Hansmann, of St. Gallen. Supplementary strips of cloth are supplied to replace the original strip when worn out. Price 1 franc." This instrument, our correspondent thinks, will lessen the number of those heroic Germans who can say, "I take a bath every six months whether I require it or not."

TEA CIGARETTES.

A WELL-EDUCATED PHYSICIAN has given to *Good's Smoking Journal* the following statement regarding a treat for tea cigarettes: "Quite a new and most reprehensible vice," he says, "is becoming fashionable—namely, a craze for smoking green tea in the form of cigarettes. Though adopted by some fair ladies merely as a pastime, not a few of its votaries, strange to say, are women of high education and mental attainments. Among my patients, suffering from extreme nervousness and insomnia, is a young lady highly distinguished at Gorton; and I am treating a lady married whose books are widely read, and who habitually smoked twenty or thirty cigarettes nightly over writing for their stimulating effect. The practice is increasing among ladies. At the house of a well-known lady where I visit green tea cigarettes are invariably handed round after dinner, and I know three actresses

of celebrity who give 'tea-smoking' parties twice a week, and a coterie of literary ladies in Kensington have formed a small club for the same laudible indulgence. One lady patient of mine, on break of this habit, on which she had expended nearly £2 a week, has been very liberally placed herself under private restraint. To conceal her ladyship from her husband she used an artfully contrived silver cigarette case; it resembled a bunch of keys, each key containing one cigarette. So much is the habit spreading that certain townspeople are beginning to make and stock these 'tea' cigarettes."

THE LANCHESTER CASE.

THE following is published as the text of the opinion given in this case by Mr. H. H. Asquith, Q.C., M.P., and Mr. Corrie Grant. (1) We are of opinion that Miss Lancheater cannot bring an action for false imprisonment against her father or her brothers, or against Dr. Blandford, with any reasonable prospect of success. Persons who put the machinery of the Lunacy Law in motion are protected against any civil or criminal proceedings if they act in good faith and with reasonable care (as in *the Victoria*, 6 Q.B. 349). In the case of the relatives there is no evidence of want of good faith, while the fact that they consulted a specialist in mental diseases, such as Dr. Blandford, is known to be, is direct proof that they did act with reasonable care. In the case of Dr. Blandford, his certificate itself, frankly setting forth facts which are not irreconcilable with sanity, is some evidence of good faith; his inquiries elicited the facts to which he certifies, and these facts are admittedly true. It may be that he was wrong in his deductions from those facts. If so, he committed an error of judgment, but an error of judgment is not actionable unless it proceeds from a want of reasonable care and skill, of which we see no sufficient evidence. (2) In an action for libel against Dr. Blandford, Miss Lancheater would have to prove that the certificate, which is clearly a privileged document, was false in fact—an allegation in which she would fail. (3) Proceedings by Mrs. Gray against Henry Vaughan Lancheater for assault would not raise the question of the legality of Miss Lancheater's seizure and detention. To such proceedings he would answer successfully that he was acting under the authority of the urgency order, that Mrs. Gray interfered to prevent the removal of his sister, and that he used no more force than was necessary to carry out this purpose.

IMMUNITY FROM THE EFFECTS OF SNAKE VENOM.

DR. H. J. LLOYD (Barnmouth) writes: I was interested in reading Mr. Harry Bawa's communication with regard to the above question published in the *BRITISH MEDICAL JOURNAL* on November 5th. Two years ago last summer a boy, 12 years old, was brought to me suffering from a bite from a common adder or viper, which measured 10 inches in length, with a flat head and brown in colour. Whilst playing with it in a field the snake suddenly sprang at his wrist and clung tight in about twenty minutes the boy was collapsed, and diarrhoea set in. He had to be carried for about two miles down a mountainous road, and when he reached here he was foaming at the mouth and vomiting something like mucus. I gave him some stimulants, when he gradually improved; I then administered some soothing applications to his wrist, as it became very painful and inflammation extended up to the shoulder; this necessitated keeping him in bed for over a week. After the inflammation abated his arm was stiff for a long time. He was a strong boy or the consequences would have been more serious. Could the act of teasing the creature have made the sting more venomous, as the boy was preventing the viper from escaping?

A SHIRT-THREADING SHUTTLE.

MR. JOSEPH HARRISON, L.R.C.P.S. (Bradford), writes: I wish to draw attention of all persons connected with textile weaving to a shirt-threading shuttle, which has been introduced into this country by Mr. C. H. Haddow, of Bradford. I do so on sanitary grounds, because it will prevent the sucking of the web through the eyelets of the present constructed shuttle. If adopted it will prevent any disease from being communicated from one person to another by means of the mouth as may happen at present. The simplicity and effectiveness of the shuttle are marvellous. It is a device which should be universally adopted in all textile manufactures throughout the world. I am confident from practical experience among textile employees that a great amount of suffering would be prevented by its use. Just imagine a weaver suffering from some mouth disease (syphilis, for example) sucking the thread through the eyelets as at present, and then that same shuttle is used by another weaver and sucked in the same way. It is no stretch of the imagination to see how such disease may be communicated by this method of sucking. Again, there are bits of fluff or fly inhaled in this way, and thus pulmonary diseases may be generated. All these evils would be prevented by the adoption of this shirt-threading shuttle, and I can most sincerely recommend it to all interested in the health of all textile employees who have to use shuttles.

COWHING PORTULACA.

THE publication, some months ago, of a short note from a correspondent describing the use of cowhage as a poultice, has brought us a large number of communications and others continue to reach us, showing that this curious practice is still pretty extensively followed by various parts of the world. Thus Dr. W. B. Brown writes from Johannesburg that he has known of its use in South Africa, America, Germany, Austria, France, and Italy. He has also known the dung of various animals administered internally for dyspepsia and the catarrhs.

It is generally known that cowhage was very widely used by the older physicians, and prescriptions containing it are to be found in innumerable old works. Dr. Traill's *Medical Jurisprudence* (Glasgow) points out that in the *Pres. Royal Acad.*, published in Edinburgh at the beginning of the last century, Sir John Mearns, then the leading physician to Scotland, recommended cowhage poultices in cancer, and a poultice made by boiling cowhage in water, vinegar, or honey in various. Sometimes the poultice was made by mixing the dung with other ingredients, as, for instance, honey, vinegar, and fresh butter, recommended for swollen testicles in the same volume. Again he instances the recommendation of Dr. Archibald

AN ADDRESS ON THE STUDY OF ANATOMY.

*Delivered at the Opening of the Section of Anatomy and Histology
at the Annual Meeting of the British Medical Association
in London, July-August, 1898.*

By HENRY MORRIS, F.R.C.S.,

President of the Section.

GENTLEMEN.—It is my first and very pleasant duty to offer a hearty welcome to the members and visitors of the Association attending the Section of Anatomy.

I do this on my own behalf, and on behalf of the executive by whose favour I have been placed in the position of President. Let me next make a few personal remarks, and say that, whilst I highly appreciate the honour which has been done me by being elected President, it was only with great diffidence, and after conferring with the President of the Branch and one or two active officers of the Association that I accepted. As a practising surgeon I felt much hesitation in accepting the office which I thought would be more suitably and, I am very certain, would be much more ably filled by a Professor of Anatomy.

I felt this the more because this is the first time that a separate Section has been made for anatomy at any of the meetings of the Association.

Since the Section of Physiology was instituted in 1867, anatomy has a few times been included under it; and in 1882 Sir G. M. Humphry, who had presided over the Section of Physiology in 1873, again occupied the Presidential Chair on the first occasion that anatomy and physiology were combined. This inclusion of anatomy under the Physiological Section once begun, was continued in four out of the five years since, in which there has been a Section of Physiology, namely—in 1883, 1888, 1890, and 1893. In 1884 anatomy was again excluded.

This year it is honoured by a place alone, and I have no doubt that the excellence of the work accomplished will fully justify the opportunity afforded.

It must be conceded that anatomy is worthy of having, and at a meeting in a great centre like the present ought to have, a Section devoted to it; and the Council of the Association, by the present arrangement, have shown themselves alive to the importance, to the rapidly growing importance, of anatomy at the present time.

It is not so many years since the student was led to regard human anatomy as a finite and well nigh exhausted science. It was held that the great impulse which had been given to it in the sixteenth century, and the assiduity with which it had been studied during the last four centuries, had left little or nothing to be discovered. A little retrospect, however, soon convinces one that in reality there has never been a period when there was the least prospect of a limit being found to the anatomical horizon; that on all occasions when its bounds seemed to be approached, some vista of things unknown loomed in the shadow, and required to be investigated and described.

The descriptive anatomy which had been worked out from dissections, and taught by Vesalius and Eustachius, by Albinus, and even in later days by Hunter, is but a small part of the vast science as it is known and studied now, and which includes histology, embryology, and morphology.

Instead of being a limited and completed subject, anatomy in this wide sense is comprehensive enough to occupy much of the daily life of many different sets of workers; and even human descriptive anatomy, owing to the largely extended range of surgical possibilities and triumphs, has been revised, corrected, and elaborated, with the result that many of the old time-honoured descriptions have been found to be either incomplete or actually erroneous.

Attention, too, has of late years been directed to important modifications which occur in structures owing, on the one hand, to excessive or specialised use, and on the other hand to want of use. We have become alive also to the deficiency of our knowledge of the anatomy of infancy and childhood; and we see now how desirable it is that this important branch

should be fully worked out and recorded, if only with the view to improvement in the treatment of children's diseases, in infant feeding, and in the early physical and mental training of childhood.

The anatomy of the brain and nervous system has been almost rewritten within the last eight or ten years, and fresh advances in it are still being rapidly made.

Though much light has been of late thrown on some of the structures and relations of structures in the human body by the study of comparative anatomy and embryology, it is pretty certain that there is very much more to be discovered in this direction by further similar researches.

Is it not probable that some intelligible explanation will be found for many of the countless variations of all kinds which occur in man, and which we at present are prone to regard as defects in a completed and perfected mechanism, or as mere abnormalities in a definite conformation?

May we not look in the near future for some classification and arrangement of the infinite details of human anatomy, details which have been accumulated, like grain in a bushel measure, without a question as to what they mean? Is it not reasonable to think that there are laws which regulate and correlate these details, and which the further study of histology and morphology will sooner or later disclose to us?

We know, for example, that the arterial system is developed from a network of connective tissue cells, and that its branches grow from the periphery to the centre of the body, and we see in this a reason why vessels follow the connective tissue septa, why they enter organs at their sulci and fissures, why they run between their lobes and lobules, and why so-called abnormalities of blood vessels accompany the departure of other structures from their usual arrangement in the body. Shall we not some day know more as to what it is which governs the shape and size and movements of the joints; the disposition of the fasciculi of muscles; their nerve supply; and the relations of the great muscular planes?

Whilst descriptive anatomy is the foundation of brain and orthopedic surgery, of the surgery of the arteries and of the abdomen; and whilst morphology has built up a new classification of, and a fresh interest in, the whole subject of tumours; embryology and developmental anatomy have greatly helped in elucidating many difficult and previously unexplained subjects in pathology. By their aid we have been taught the origin of median cervical fistulae; of tubulocysts and dermoids of the tongue, and of dermoids in the skull owing to the mode of development of the dura mater and of the pituitary gland in relation to the skin. By the same means, too, we have learnt the mode of occurrence of such congenital malformations as hypospadias, epispadias, imperforate anus, congenital occlusion of the pharynx, and many others.

So likewise it is certain that as morphology comes to be more and more pursued it will be found to yield more and more information about disease; and that in this connection the minute and accurate observation of variations in form and texture will take rank with, if not in front of, the chemical analysis of solids and fluids of the body, and the new science of bacteriology, which, indeed, is itself a branch of morphology.

It is impossible to foretell the extent of knowledge which may be gained by this study, and I should no doubt be accused of speaking in folly or in irony if I were to predict that the time will come when, by a morphological examination of the placenta, not only much of the tissue condition of the parents at the time of impregnation and conception would be ascertainable, but that the physical, mental, and moral attributes of the offspring will be foretold; so that it will be possible, in anticipation, to classify him with the athlete or the cripple, the genius or the idiot, the total abstainer or the inebriate. Yet things quite as improbable have happened.

I have thus referred to some of the pathological and clinical advances which surgery owes to anatomy; and to the importance of that modern branch of anatomy—morphology—as a means of elucidating changed and diseased action; but I would not be supposed to entertain the opinion that it is from that point of view alone that anatomical knowledge should be pursued.

New facts should, of course, be recorded for their own sake, whether they appear to be of any practical value, or to explain any interesting hypothesis or not, for one never knows how soon a fact which apparently stands alone may turn out to be a link in the chain of evidence which is required to prove a special or general law.

As a means of cultivating the power of observation, and stimulating and exercising the reflecting and reasoning faculties, the study of anatomy is of high value; and it is engrossing enough to occupy the greater part of the intellectual activity of many powerful minds. It is owing to this very scope and depth of the subject that the transcendental anatomist is sometimes led to express impatience, even if not contempt, that anatomy is still commonly taught in medical schools pretty much as it was a century ago. The pure anatomist feels somewhat outraged that his science should be treated as though it were simply subservient to the requirements of the operating surgeon, and the practising physician.

He objects, and very properly, to the custom of allotting to the physiologist, under the heading of "the physiology of movement," the teaching of the actions of muscles, which after all are necessarily dependent upon their origins and insertions and nerve supply. He resents as an injustice the proposal that teratology, if it came to be taught in medical schools, should be entrusted, as it probably would be, to the obstetrician, and that thereby a purely morphological subject would be divorced from its natural and immediate connection with anatomy. He would have all medical students taught the highest anatomy in the early period of their curriculum; and is not content with an eminently practical course of human anatomy, even when aided by explanations and illustrations from comparative anatomy and embryology.

May I be allowed to take this opportunity of expressing my opinion, based on several years of teaching and examining, that there is not time enough for the student thus to study anatomy; at any rate, not until he shall have been afforded some relief from his present long course of dissecting, as we shall, I believe, presently hear Professor Anderson advocating he should be. By all means let us open his mind to the depth and width of the science, pointing out its many-sidedness to him; but the study in its fulness must come later on in his career, if it comes at all.

The amount of knowledge the student has to acquire in order to gain a diploma is at the present time simply enormous, and I am entirely in accord with Huxley's remark that "whoever adds one tittle that is unnecessary to medical education is guilty of a very grave offence"—an offence, by the way, which I hope I am wrong in thinking there seems to be in some quarters a tendency to commit.

Whilst thankfully acknowledging the indebtedness of surgery to anatomy, and the invaluable aid morphology is rendering to the study of the etiology and treatment of disease, may I also point out that, on the other hand, anatomy has received something in return from surgery? Has not topographical anatomy of late been studied with increased zeal in consequence of the expansion of the surgeon's art, and with this result, that many imperfections and errors have been expunged and many additions made by practical surgeons? Nor do I think that this branch of the subject requires a less well-trained mind, or a less acute power of observation than developmental, teleological, or comparative anatomy.

I hope I shall not be considered to have taken undue advantage of my office by thus briefly and very inadequately enumerating some of the lines of intercommunication, and some of the points of sympathetic contact between anatomy and surgery and pathology; and of thereby offering some arguments in justification of a separate section for anatomy at the meetings of the British Medical Association.

THE ANATOMY OF THE GENITO-URINARY ORGANS IN THE BOAR AND IN THE PIG, WITH REMARKS ON THE EFFECTS OF CASTRATION.¹

DR. JOSEPH GRIFFITHS (Cambridge) read the following paper on this subject: The prostate is very large and bilobed, and lies on the sides and behind the urethra. Each lobe is com-

posed of numerous small glandular lobules, held together by loose areolar connective tissue, which in the form of a thin sheet surrounds, and thus binds together, the different lobules making up each lobe; and the gland is soft and granular. Its ducts pass into the hinder or dorsal wall of the urethra. It is composed mainly of vesicles, some of which are quite small and hardly visible to the naked eye, others being large and 1 inch in diameter; and they are filled with a thin, slightly turbid mucous secretion. Each vesicle is lined by a single layer of cubical or subcolumnar epithelial cells. The vesicles are embedded in a thin layer of tissue, mainly composed of unstriated muscular fibres, and traversed by blood vessels, lymphatics, and nerves. Cowper's glands also are very large, each measuring four and a-half inches in length, and at the lower and larger end one and a quarter inches in thickness. They are firm, elongated, three-sided pyramids, lying one on either side of the urethra, and having over the hinder part of their outer surface, and all over the dorsal or posterior surface, a sheet of reddish-striped muscle with the fibres running from behind outwards and forwards on to the dorsum. In the middle of each is a large dilated branching duct into which the smaller ones open. The smaller ducts commence in the glandular substance proper, which is subdivided by thin fibrous partitions into small compartments. The main duct narrows as it passes out at the posterior extremity of the gland, rendering it probable that the main duct, and also the smaller ducts, act as reservoirs for collecting and retaining the secretion of the gland, which is thick and viscid. The ultimate gland lobules are composed of numerous small vesicles lined by a single layer of columnar cells lying on a basement membrane, which consists of a single layer of flattened connective tissue cells. The columnar cells have small nuclei near their attached ends, and their protoplasm is clear and almost transparent. The vesicles are separated from one another by the minimum amount of connective tissue, without unstriated muscle fibres in it. Cowper's gland thus differs from the prostate in having no unstriated muscle in its substance, and in having a thick sheet of striped muscle partially covering the gland on its outer surface, which serves the purpose of expressing its secretion. The sheet of striped muscle around the intrapelvic part of the genital portion of the urethra is thick, of red colour, and well formed. The muscular fibres are of full size, and they present the usual structure of normal striped muscular fibres. In a full-grown pig, which when a few days old was deprived of the testes, the condition of the parts presents a striking contrast. The prostate is represented by two small, flat, bean-like masses, which are firm, and composed of small compact lobules held together by means of loose areolar tissues. Each lobe is one inch long, and one-third to one-fourth of an inch broad. Each lobule is composed of a number of tubules with thick walls, consisting in the main of fibrous connective tissue with a few unstriated muscular fibres, and lined by a single layer of subcolumnar cells. In many of the tubules there is a small lumen, but in others the interior is filled with cells. The tubules in a lobule are connected together by somewhat dense fibrous connective tissue, though the lobules themselves are connected only by a small amount of loose areolar connective tissue. Cowper's glands are small elongated pyramids. They measure 2 inches in length and one-fourth of an inch in thickness at the lower and larger end. The striped muscles on their outer surfaces is correspondingly small. They are mainly composed of ducts, which are filled with a mucous secretion. The peripheral part of the gland is composed of numerous closely-packed vesicles, which have hardly any lumen, and are lined by a single layer of subcolumnar cells, with clear protoplasm. The sheath of striped muscle around the intrapelvic portion of the urethra is thin and fibrous, and the muscular substance is pale. The individual muscular fibres are of small size, and about half the size of those in the same muscle in the boar. The contrast between the accessory sexual glands in the boar, and the same glands in a pig castrated when young, clearly shows that the testes exert an all-important influence upon the growth and development of the accessory sexual glands, and that the full development of the striped muscle around the urethra is dependent upon the existence and full development of the testes.

¹ Read in the Section of Anatomy and Histology at the Annual Meeting of the British Medical Association held in London, July-August, 1895.

THE DEVELOPMENT AND STRUCTURE OF THE PLACENTA.

Professor A. H. Young (Manchester) introduced a discussion on this subject. He said: Our knowledge of the development and structure of most of the organs of the body is fairly full and accurate; this is mainly due to the greatly improved methods of preparing tissues for examination which have been so recently introduced and adopted, and to the more careful and extended observations which have naturally resulted. Unfortunately we cannot claim any such exact knowledge either of the development and structure of the placenta or of its functions and the part it plays in health and disease. There has been no dearth of observations on these points; indeed, few organs have been so much studied; but the contradictory nature of the results obtained, as well as the singularly clashing hypotheses which have been formulated by different observers, make it practically impossible to arrive at any definite conclusions regarding the essential features of its formation and structure. The general function of the placenta is undoubtedly the nutrition of the fetus. We no longer believe, as Fabricius, Haller, and Flourens did, that nutrition of the fetus is maintained by the direct passage of blood from the mother, the placenta acting merely as a blood conduit. This hypothesis was long ago completely disproved by Monro, William Hunter, and Bischoff. It is possible that nutriment may be transmitted to the fetus by the placenta in one or more of the following ways: (1) The fetal part of the organ may absorb secretions poured out by uterine glands or crypts; (2) fetal tissues may destroy and absorb maternal structures; (3) interchanges may take place between maternal and fetal blood, either (a) as the result of an active process of secretion or (b) by diffusion. That uterine secretions may suffice for the support of the ovum during a considerable period of its development is shown by Selenka's observations upon marsupials. In them there is no true placental formation, and the growth of fetal tissues must be dependent upon the absorption of uterine fluids; it appears certain also, from the observations of Turner, Bonnet, Tafari, and others, that nutriment is derived from a similar source in ruminants, but it is doubtful whether even in ruminants this occurs in the placental areas themselves, and there is no doubt that in rodents (Selenka, Duval), insectivora (Hubrecht), and in cheiroptera (Frommel, Selenka) such a mode of nutrition is excluded by the early disappearance of uterine glands in the superficial parts of the placental area. In carnivora, primates, and man the amount of nutriment derived from glandular secretion can scarcely be estimated; indeed, no positive opinion can be formed until the relationship between the fetal villi and the uterine glands is more definitely ascertained and determined. It seems very probable that the maternal tissues are utilized for nutrition, for degenerated uterine epithelium disappears, and there is no evidence that it is removed by the maternal cells, or that it is absorbed by maternal vessels, whilst, on the other hand, portions of maternal detritus, for example, blood corpuscles and blood crystals, have been observed in the cells of the fetal villi, presumably being used for nutrition, since it is scarcely probable that they would be taken into the fetal tissues for any other purpose. The close relationship which exists in the placenta between maternal and fetal blood at once suggests that interchanges, both nutritive and respiratory, may take place, and our views as to whether this is the result of an active process of secretion or whether it is due simply to diffusion must be influenced largely by our knowledge of the structure of the organ. Those observers who maintain that layers of epithelium intervene between the uterine blood vessels and those of the chorionic villi believe that the process of transmission of food from mother to fetus is rather due to an act of secretion than to one of diffusion, but if it can be shown that both maternal and fetal epithelium disappear, then the theory that the nutrition of the fetus is due to a process of secretion depending on these cells must disappear also, whilst it becomes evident that under such conditions interchanges might readily take place by diffusion. In the placenta of the rabbit Duval has shown that there is complete disappearance of both fetal and maternal epithelium as intervening structures between the maternal and fetal blood, and that the fetal capillaries, whose walls are

formed by a single layer of flat endothelial cells, project freely into spaces containing maternal blood by which they are bathed, whilst the gases necessary for the metabolic phenomena which are known to occur in the fetal tissues can scarcely be imported from any other source than the maternal blood nor by any other process than diffusion. It must, however, be admitted that in most mammals the relationship of fetal and maternal blood is by no means so intimate as in the rabbit. That there should be differences of opinion as to details of function is obvious when the numerous accounts of the development and structure of the placenta are studied, for it is with respect to the details of formation that the statements of observers are so irreconcilably opposed. Upon two points alone is there general agreement: one is the dual nature of the organ, which it is admitted consists of fetal and maternal elements; and the other is the villous character of the fetal portion. As to the relative proportions of the fetal and maternal parts, or the precise relationship which exists between them, or the exact nature of their constituent elements, there is no such agreement. We are assured by some investigators that the fetal villi pass into the mouths of uterine glands; by others that they do not enter the glands, but project into newly formed crypts; and by others, again, that they avoid both glands and crypts, and either fuse with or penetrate the uterine mucosa in the interglandular areas; finally it is said that the fetal villi pass into newly formed spaces of glandular nature, but which are lined with modified connective tissue cells. It is still a matter of dispute whether one or two layers of epithelium separate the maternal and fetal blood vessels, and if one layer only, whether it is fetal or maternal, and if two layers, whether both layers are fetal, or whether one is fetal and the other is maternal. Duval's observations on the placenta of rodents shows that in some cases at least there is not even a single layer of epithelium, and nothing intervenes between the two blood streams but a layer of fetal endothelium. It has long been known that in the human placenta, and in the ape's placenta, the fetal villi are surrounded by intervillous spaces, and it is generally, though not universally admitted that the spaces contain maternal blood, but observers are by no means agreed as to the nature of these spaces. In the opinion of Turner, Ercolani, Weber, Reid, and Waldeyer they are dilated capillaries or veins, with intact endothelial walls, which are merely invaginated by the foliaceous villi; Leopold and Virchow think that the villi perforate the endothelium and are bathed in maternal blood. Koelliker, Langhans, and Heinz look upon the spaces as extravascular; according to Koelliker, they are bounded in the greater part of their extent by epiblastic cells of the fetal villi, a view strongly supported by Minot's observations, and which has recently been confirmed by Berry Hart and Gulland. It is also generally admitted that whatever the final arrangement may be it is preceded by a stage in which the chorion of the ovum is applied against, but is not attached to, the epithelium of the uterus, and that at a later period either the maternal or fetal epithelium disappears. It has recently been suggested, however, that the human ovum is not implanted on an epithelial surface, but becomes attached to a raw area, produced by exfoliation of the surface layers, where it becomes gradually imbedded as the decidua is formed, in which case there is no "decidua reflexa"—this being replaced by the last formed part of the "decidua serotina." If this could be accepted there would be no trouble in explaining the absence of maternal epithelium in the intervillous areas, but placental formation in the lower mammals is entirely opposed to such a mode of attachment, and human uteri containing ova or oes have not been observed at a stage when one might reasonably expect that the maternal epithelium was still present. Obviously then our knowledge of the development and structural details of the placenta is not very definite or precise. We recognize its dual character and the intimate relationship of its constituent parts; we know that one or more layers of tissue intervene between fetal and maternal blood, but we cannot say precisely what the relationship of fetal and maternal portions is, and we are equally uncertain of the origin of the layer or layers which lie between the two blood streams. That such should be the unsatisfactory result of much good work carried out by most able investigators, is, I think,

entirely attributable to the fact that until recently few, if any, of the observations have been sufficiently comprehensive. In many cases a few specimens only of uncertain or unknown stages of development have been examined. No individual point has been fully worked out from beginning to end and from stage to stage in any one mammal, and yet nothing short of such a comprehensive investigation can be accepted as a reliable basis for general conclusions. If we are to hope for a sound knowledge of placental formation and structure, we must have careful and complete observations on a consecutive series of stages, from the period just preceding the fixation of the ovum to the period when all the details of the adult organ are completed. Observations of this nature have been made by Hübner and Strahl upon insectivora, by Frommel and Gohre upon cheiroptera, by Minot, Duval, Strahl, and Robinson upon rodents, and by the last three as well as by Heinrichs and Lusebrinck on carnivora. It is evident that our knowledge of the human placenta must necessarily be incomplete. No one, so far as I know, has yet obtained anything like a satisfactory series of stages of human placental development, and our views concerning it must to no small extent be based upon a comparison with conditions satisfactorily established at certain periods in lower mammals. One of the most striking features in placental development is the important part played by the fetal tissues, the fetal epiblast in particular, and this is the more noticeable as it is opposed to the views hitherto almost universally held. It is true that in the early stages the uterine mucosa increases in thickness, its glands become enlarged and more tortuous, the interglandular substance proliferates, and foldings of its surface may produce crypts. The glands and newly formed crypts, so well marked in the carnivora, play but a secondary part in the further stages, they merely dilate and their epithelial lining degenerates and disappears, serving apparently as pabulum for the fetal tissues. The secondary importance of the glands of the mucosa is emphasised by their fate in the placental areas in rodentia, insectivora, and cheiroptera, in which they undergo little or no increase, and in the later stages are entirely occluded (from the fetal tissues) by cell elements apparently derived from connective tissue or by endothelial cells. The most important maternal structures are the capillaries; these proliferate and dilate and form a more or less well marked superficial layer immediately subjacent to the surface of the ovum. The fetal part of the placenta, on the other hand, is energetic and aggressive. Its epiblast proliferates and becomes greatly thickened, and apparently destroys and absorbs the maternal epithelium, though Strahl and Lusebrinck assert that the maternal epithelium persists, though in a changed form, and continues to intervene between the epiblastic cells of the chorion and the deeper maternal tissues. The epiblast next invades the modified uterine mucosa, either, as in the carnivora, entering but apparently not passing beyond the mouths of glands and crypts in the form of hollow villous projections which soon become filled with fetal mesoblastic elements, or as solid sprouts of epiblastic cells which penetrate the uterine decidua and insinuate themselves between the maternal capillaries. The process of invasion is carried to its greatest extent in rodents; in the rabbit, for example, the epiblastic cells surround the maternal capillaries, destroying and replacing their endothelial walls so that the maternal blood then circulates in spaces surrounded by fetal epiblast. By the outgrowth of the allantois the allantoic vessels reach the deep surface of the thickened placental epiblast, penetrate it, and thus bring the maternal and fetal blood streams into close proximity. At this stage the two blood streams are separated by fetal elements alone, namely, fetal epiblast and the endothelial walls of fetal vessels. At a later period still the epiblast disappears, the fetal vessels lie naked in the maternal blood, and nothing intervenes between the two blood streams except fetal endothelium. In short, the thickened placental epiblast is tunnelled by great blood spaces, which communicate with maternal blood vessels, and into which the fetal blood vessels freely project, uncovered by any epithelial investment. A modification of the process occurs in the rat and mouse, but the main features are essentially the same. In carnivora the epiblastic invasion is less marked, at least in

the early stages, and it never goes so far as to destroy the endothelial walls of maternal blood vessels. It remains for a time comparatively superficial, and there is coincident proliferation of the vascular layer of the decidua. The intermixed fetal epiblast and maternal capillaries, both in rodents and carnivora, constitute a layer which Duval has termed the "angio-plasmoidal" layer, and it is to this that the greater part of the increasing thickness of the placenta is due. To summarise: the structures which intervene in the placenta between the fetal and maternal blood streams are not the same in different groups of mammals. Confining our attention to the two groups which have been most thoroughly investigated we see that in the carnivora the fetal blood is separated from the maternal by three layers: 1. The endothelium of the maternal vessels. 2. A layer of fetal epiblast which generally contains two rows of nuclei, and is not divided into cell areas, but is of the nature of a plasmodium. 3. The endothelium of the fetal vessels. In rodents, however, according to Duval's observations, there may be only a single intervening layer separating the two blood streams, and that is the endothelium of the fetal vessels. We thus arrive at the following conclusions concerning placental development and structure: 1. Fetal tissues play a most important part in placental development, they invade, destroy, and devour maternal substance. 2. The maternal tissues pass through three phases; they exhibit a remarkable activity before the fixation of the ovum, this is succeeded by what may be looked upon as an irritative proliferation due to the invasion of fetal epiblast, and finally they disappear in great part coincidentally with the epiblastic advance. 3. The relationship between the fetal and maternal blood streams may be much more intimate than has usually been believed; and in any case the intervening structures are chiefly fetal. 4. The uterine glands and crypts play a comparatively unimportant part in the placental area; they are not penetrated to any great extent by fetal villi, but their epithelium degenerates and disappears, and is utilised as fetal pabulum, except at their terminal extremities, where it remains almost unchanged to serve for the regeneration of the surface after parturition. These general facts, which have been established by observations on lower mammals, enable us to form a fairly definite conclusion regarding the layer of epithelium which forms one of the intervening strata between the two blood streams in the human placenta, and there can no longer be any doubt of its fetal origin; it is certainly fetal epiblast. Unfortunately comparative observations do not enable us to decide between the conflicting statements regarding the number of the other intervening layers. There is no doubt that the endothelial walls of the fetal vessels persist, but although it is very probable that the maternal endothelium is absent, yet this has not been proved. It appears certain that two layers separate the maternal from the fetal blood—namely, fetal endothelium and fetal epiblast, the latter consisting of two strata in the early stages, but of one only in the later periods, and it is possible that a third layer—the maternal endothelium, may also be present. We cannot deny that this may be the case, for we know that a similar arrangement is present in the carnivora, nor can we assert that it is impossible that two strata only separate the two blood streams, since it has been shown that such a condition is present for a considerable period in rodents. We must therefore be content to wait until more complete investigations have been made. No description of the structure of the placenta can be considered complete without some reference to its relation to the allantois and to the hypoblast of the fetus. This subject has received but little consideration. It is known that in many mammals the allantois consists of a diverticulum from the alimentary canal covered with vascular mesoblast. It grows from the posterior end of the body of the embryo, and after a time unites with the chorion, to which it conveys the allantoic vessels. It gradually spreads out on the inner surface of the placental area, and thus its hypoblastic lining lies on the fetal surface of the placenta. The hypoblastic cells, which usually become flattened, do not apparently play any very active part. The allantois has usually been regarded as an enlarged urinary vesicle, modified for respiratory and nutritive purposes, and as these functions are presumably fulfilled by the vessels, but little attention

has been paid to the hypoblastic lining, a circumstance which at first sight appears to be justified by the fact that in some mammals the hypoblastic diverticulum is absent, and the allantois consists only of mesoblast. It has been shown, however, that in some rodents in which this condition is well marked the absence of the hypoblast-lined cavity in the allantois is compensated for by the projection of diverticula from the wall of the yolk sac into the placenta, and in this manner the fetal hypoblast enters the placental region. It appears, therefore, to be a matter of some importance that not only the fetal epiblast and mesoblast should gain a close relationship with the maternal blood, but that the fetal hypoblast should also participate in the intimacy, but the object of this arrangement has yet to be discovered. In the meanwhile it is evident that there are many points relating to the development and structure of the placenta which may well be discussed both by the embryologist and the histologist, and beyond this, also, by the pathologist and the gynecologist, who will find in the developmental history of the placenta the keynote to many obscure problems of uterine and placental disease. One cannot, for example, fail to observe the remarkable similarity between the early stages of placental formation and those seen in the development of malignant epithelial tumours. In both there is epithelial proliferation followed by epithelial invasion and accompanied by irritative phenomena in surrounding tissues. During placental formation the maternal tissues are invaded by fetal epiblastic cells, much in the same way that the sub-epithelial stratum of skin or mucous membrane is encroached upon by proliferating epithelium in cancer formation, and it would not seem impossible that normal placental epithelial changes might, under certain circumstances, lead to true carcinoma. There can be little doubt that the fetal epiblast grows at the expense of the maternal tissues, and there seems no reason why any portions left behind on the separation of the placenta should not continue to grow, and, invading still further the uterine mucosa, assume all the characteristics of a definite tumour growth. I venture to draw attention to this point in a paper read before the North of England Gynecological Society some three or four years ago, and I then referred to the most interesting case recorded by Dr. H. Meyer, of an epitheliomatous growth which followed the removal of a hydatiform mole. The epitheliomatous character of the new growth was clear, and the resemblance of the invading columnar processes to chorionic villi, as previously pointed out by Professor Klebs, was apparently fully recognised, but nevertheless Dr. Meyer suggests that the epithelial element was probably of maternal origin and that into it chorionic villi had protruded. This, however, does not seem a probable sequence of events, whilst the changes which are known to take place in the development of the placenta gives strong support to the view that the epithelial element was in all probability fetal. This again is emphasised by a similar case described by Fraenkel as "carcinoma developing from the chorionic villi." This case was one of malignant disease of the corpus uteri following the removal of a vesicular mole. "The growth had a papillary form, invaded the deeper tissues, and gave rise to metastases. Microscopically it was shown to have originated from the remnants of chorionic villi left after removal of the mole, since the structure of the uterine glands was still recognisable, and its histological appearance was quite different from that of cancer of the corporeal endometrium." That uterine tumours may originate from placental relics is fully recognised by Hartmann and Toupet in their valuable memoir on the "Later Evils following Retention of Placental Relics." Amongst the most interesting of these growths is the malignant deciduoma, a tumour apparently regarded as of sarcomatous nature, to express which Sanger suggested the name of "sarcoma deciduo-cellulare," whilst Hartmann and Toupet designate it as a chorion cell sarcoma. From the excellent description given by Dr. Williams at the Johns Hopkins Hospital Medical Society in November, 1891, of the fourteenth case of deciduoma malignum recorded up to that time, it does not seem by any means so certain that these tumours are invariably of the sarcomatous nature they are supposed to be. The cells at first sight are said to "closely resemble epithelial cells," but from their similarity to the cells of the decidua they are regarded as

identical with them, and the entire growth is looked upon as "a sarcoma arising from the decidua." Dr. Eden, in a preliminary communication on the development and normal structure of the placenta, states that the large decidual cells are really epiblastic cells, and if this is so the sarcomatous character of the tumour becomes more than doubtful. Clearly the study of abnormal conditions occurring in connection with placental formation should be based upon accurate observations on the development and structure of the normal placenta. With a fuller knowledge of the structure of the placenta and of the exact relationship of the fetal and maternal blood streams, we shall understand better the important question of the transmission of disease between mother and fetus. In short, a wide field for experimental observations will be open, and it is by such observations alone that we can hope to obtain satisfactory results.

The President congratulated Professor Young on his very valuable paper, and suggested that investigations should be directed to the occurrence of cancer at different periods of gestation, as he thought that this might help in the elucidation of the pathology of cancer.

Mr. ROBINSON emphasised the fact that no accurate conclusions could be drawn concerning the development of the placenta, unless a complete series of sections and specimens were examined. Many older observers had been led astray by examining incomplete series of specimens, and on this account he recommended that no definite conclusions should be drawn from the examination of a single specimen.

Mr. C. B. Lockwood said that he had prepared and examined many examples of developing mice and rabbits, and in mice he had seen similar appearances to those described by Professor Young, but owing to the incompleteness of the series he had not been able to interpret all the things which were seen. In an examination of a very early human embryo he had observed many resemblances in the development of the placenta between it and that of the rabbit.

Professor CUNNINGHAM agreed with the conclusions of Professor Young, and said that the School of Anatomy of Owens College had been especially associated with work which had been done in the elucidation of the development of the placenta.

THE TOPOGRAPHICAL ANATOMY OF THE ABDOMEN.

PROFESSOR A. THOMSON (Oxford), after a few preliminary remarks, in which the work done by Professors W. Anderson and D. J. Cunningham was referred to, went on to criticise the generally-accepted system as described in *Quain*. He took exception to it on the following grounds: To only two of the nine regions described do the descriptive terms correctly apply, namely, the umbilical and hypogastric areas. The hypochondriac regions are in no sense strictly hypochondriac. The epigastric region includes considerable portions of both hypochondriac. The term lumbar region as applied to the flanks is a misnomer, and the iliac regions are misleading, as they do not include the whole of the iliac fossae. In view of these facts Professor Thomson urged that it would be well to discard such misleading terms where necessary and see if some scheme could not be devised so as to modify the delineating lines and bring them into harmony with as much of the existing nomenclature as it is advisable to retain. As essentials to any satisfactory system Professor Thomson laid stress on the following points: The delineating lines should pass through fixed points. These fixed points should be readily accessible without undue exposure and disturbance of the patient in bed. The lines should be straight and not curved. After a further discussion of the existing symptoms, Professor Thomson held that that which presented most advantages and entailed the least alteration in the present nomenclature was one in which the surface of the abdomen was mapped out as follows: The following fixed points were taken: (1) the centre of the articulation between the lower end of the sternum and the ensiform cartilage; (2) the anterior superior iliac spines; (3) the most dependent part of the tenth costal arch; and (4) the symphysis pubis. Of this, No. 3 was open to most objection, but it seemed hard to find a substitute. As Professor Cunningham had pointed out, the lower costal margin is liable to very great individual variation, and hence

far from satisfactory. Failing a better, however, it was determined to adopt it. The delimiting lines, as represented in the accompanying cut, were marked in as follows: Two horizontal lines were carried across the surface of the abdomen, one on a level with the most dependent part of the tenth costal arch. This line was called the subcostal line. Another, called the interspinous line, connected the two anterior superior spines of the ilium. Lines were drawn from the centre of the xiphisternal articulation to the anterior superior iliac spines on either side. These were called the ilio sternal lines. In this way a triangle was constructed, the base of which corresponded to the interspinous line, whilst the sides were

formed by the ilio sternal lines. It was pointed out that the part of this which lay above the level of the subcostal line corresponded with fair accuracy to the region between the converging costal margins. Further, Professor Thomson emphasized the necessity of recognizing the practical advantages of the middle line reaching from the xiphisternal articulation to the symphysis pubis. Though universally employed in clinical work, this line has never been made use of in any of the British systems of delineation so far as he was aware. Such a line subdivides the triangle above described, and further halves the region which lies below the interspinous line. By such an arrangement of delimiting lines, the surface area of the abdomen is marked off into ten regions, to which it seems advisable to apply the terms:

Regio hypocondriaca dextra.	Regio epigastrica dextra.	Regio epigastrica sinistra.	Regio hypocondriaca sinistra.
Regio ab- dominalis lateralis dextra.	Regio umbilicalis dextra.	Regio umbilicalis sinistra.	Regio abdominalis lateralis sinistra.
	Regio inguinalis dextra.	Regio inguinalis sinistra.	

As will be seen, the term lumbar region is discarded, and the terms inguinal regions are substituted for the iliac fossae. In regard to the latter, Professor Thomson pointed out that this was rather a gain, for the iliac fossa is in reality traversed by the interspinous and ilio sternal lines, and thus greater accuracy may be attained in locating a tumour in this region, as its extent may with precision be measured along these respective lines. It was claimed as an advantage that with little difficulty lines in correspondence with the foregoing could be easily marked off on the back of the trunk. Thus the middle line of the back, on a level with the inferior angles of the scapulae when the arms are by the sides, corresponds fairly accurately to the centre of the xiphisternal articulation. The position of the anterior superior iliac spines can be determined in the following way. A line is drawn across the root of the back a finger's breadth below the level of the posterior superior iliac spines. The middle third of this line corresponds to the interval between the two posterior superior iliac spines, and the extremes of its outer thirds overlie the spot on the back of the body, which agrees with the position and level of the anterior superior spines. Having ascertained these points there is no difficulty in mapping in the lines and regions in agreement with these

in the anterior surface of the abdomen. Professor Thomson then proceeded to demonstrate by a series of lantern slides the relation of the delimiting lines and planes to the abdominal viscera; the ilio sternal lines in particular, appearing to possess many advantages as aids to the localization of certain of the abdominal viscera. The system proposed by the German Committee of Nomenclature was next discussed, and exception was taken to certain features of it, it is being laid on the fact that some of the delimiting lines were curved, and that there was want of precision in regard to certain of the fixed points.

Mr. MAKINS thought that the outer border of the rectus abdominis muscle was a most useful line as a surgical guide.

Professor ANDERSON agreed with the preliminary remarks, and said that the system suggested most nearly approached a natural system, but an objection to its adoption was the multiplicity of the different methods which are made use of at the present time. If the majority of anatomists would adopt the suggested method, it might with advantage be made use of. He said that the examiners of the College of Surgeons had ceased to ask questions on the regions of the abdomen on account of the different ways in which ordinary textbooks describe them. He thought that the topography of the pelvis ought to be included in that of the abdomen.

Professor THANE said that Professor Thomson had thrown much light upon the nomenclature of the topography of the abdomen. He agreed with Professor Thomson's objections to the correctness of the names of regions, but added objections to the use of the names of the umbilical and hypogastric regions. He also objected as a rule to the use of oblique lines in the demarcation of abdominal regions, but thought that Professor Thomson had made out a very strong case for oblique lines. The inclination of the pelvis varied in the recumbent, sitting, and standing postures, and on this account the lines would not be invariable in position.

Mr. WILBERFORCE SMITH thought that the lower end of the sternum was too variable a point to be made use of as a fixed point.

Mr. C. B. LOCKWOOD said that it would be a very long time before the abdomen would be satisfactorily mapped out for physicians, surgeons, and anatomists. He deprecated the use of artificial lines, and recommended the adoption of natural lines such as the linea semilunaris. He advocated the retention of the term umbilical region, and thought that the term flank was more useful and preferable to lateral abdominal. He also thought that it would be very unsatisfactory for teaching purposes, and objected to reliance being placed upon being able to feel the posterior superior iliac spine. He advised the use of surface centres, such as McBurney's point.

Mr. JAMES BLACK thought that the lines and planes which had been proposed by Professor Thomson were very valuable, and ought to be adopted.

Professor THOMSON, in reply, said that he thought that it was easy to feel the posterior superior spine, since it could always be seen and the finger placed upon it. He did not think that the lower end of the sternum varied in position sufficiently to encourage its disuse.

THE AFRICAN LIQUOR TRAFFIC.—The breakfast given by the Duke and Duchess of Westminster at Grosvenor House a day or two ago is an evidence of the extraordinary interest taken in the efforts of the three African chiefs to preserve their peoples from the devastating influence of the liquor traffic. Khama appealed to the justice of England to secure that no violation of the existing prohibition of the traffic in intoxicants be rendered possible by any Governmental changes. The Bishop of London strongly supported the chief's eloquent appeal, and the efforts of the Native Races and Liquor Traffic Committee. In this praiseworthy effort we are glad to note that members of the medical profession are taking an active part. The editor of *Niger and Yoruba Notes*, Dr. Harford-Batterby, is endeavouring to promote international concerted action, a harmonious compact which is essential to a successful issue, seeing that so many Powers are increasing their African possessions, and extending their commercial operations over that continent.

A DISCUSSION ON THE PATHOLOGY AND TREATMENT OF PRURITUS.¹

I.—MCCALL, ANDERSON, M.D.,
Physician to the Glasgow Western Infirmary.

Is opening a discussion on the pathology and treatment of pruritus, one cannot help being impressed with the magnitude of the subject, for there are few diseases of the skin in which pruritus is not more or less present at some period of their course, and often as a leading factor in the distress which they occasion.

It is difficult to say with certainty what portions of the nervous apparatus of the skin are specially concerned with the sensation of itching, but it is highly probable that the following are mainly responsible:

1. As is well known, in some situations single nerve fibres pass up to the under surface of the epidermis, lose their medullary sheaths, and then the axis cylinder divides into extremely delicate filaments which lose themselves among the cells of the epidermis, or come into contact with cells having branching processes (the cells of Langerhans). These free nerve terminations in the epidermis endow it with a certain amount of sensitiveness, and their irritation probably gives rise to pruritus.

2. In the deeper layers of the epidermis, or in the true skin close to it, small groups of cells are found connected with nerve filaments. These cells may be regarded as simple tactile cells. Two or three such cells often form a group, taking the form of a small cup, or like a wineglass with the bottom broken off, the nerve ending in the stem of the glass, or like a small toadstool. These tactile cells are undoubtedly related to nerve endings, and when irritated they are likely to induce itching.

3. The bulbs of many hairs are related to nerve endings. Fine medullated nerve fibres form a network in the outer coat of the hair follicle, and they then lose the white substance of Schwann, and run more in a longitudinal direction parallel to the hair. They then penetrate the wall of the follicle, and end in the inner layer of the sheath of the hair. McKendrick regards each hair as more or less of a tactile organ. May not irritation of these sometimes cause pruritus, more especially when it is borne in mind that each hair has around the neck of the follicle some erectile tissue and bands of elastic and muscular tissue? When the spaces in the erectile tissue are full of blood, each hair projects from the centre of an elastic cushion, thus giving rise, doubtless, to great sensitiveness of the surface.

That the sensation of itching is due to the irritation of the nervous filaments in the epidermis rather than in the deeper parts is probable for various reasons. For instance, if the finger is applied to a tender part of the skin—such as the cheek—one is conscious of a sense of pressure; but if the part is touched very gently there is no pressure sense, but a feeling of itching leading to a desire to rub or scratch the part. Again, as has been remarked by Bronson, the itching in connection with the healing of wounds is not due to the granulating process, because there is no itching until the part begins to "skin over;" and, finally, the essentially pruriginous affections are those associated with decided trophic changes in the epidermis.

My colleague Professor McKendrick, with whom I discussed this question of itching, says, amongst other things: "I would be inclined to regard itching as a special kind of sensation—a modification of touch caused by extremely minute variations of pressure, but quite *ad generis*. In support of this view, I can produce artificial itching that is almost unbearable. Attach a bristle to the prong of a tuning fork vibrating from 400 to 800 vibrations per second, and let the end of the bristle touch the lip while the fork vibrates. An intense sensation of itching is felt that will make a man jump back and rub his lip. This is caused by rapid and delicate variations of pressure. The effect is not so striking when the bristle touches the skin, because the variations of pressure may not be fast enough, or they may not have sufficient force."

But why, it may be asked, is pruritus such a prominent

feature in some diseases of the skin, such as eczema and dermatitis herpetiformis, and generally absent in others in which we might naturally expect it to be present, as in the stromous affections of the skin? Perhaps it may be on the same principle as that which underlies the symptoms of pleurisy. If that disease occurs in a previously healthy and vigorous subject, it is generally acute and accompanied by much pain, but if it occurs in broken-down or tuberculous subjects, it is apt to be chronic, painless, insidious, and latent. But even if the analogy were complete, we are not much nearer a satisfactory explanation of the difficulty.

And how is it that itching is common in connection with the later and almost invariably absent in connection with the earlier manifestations of syphilis. It may be said that the general diminution of sensation which has been alleged by Fournier and others to attend the secondary symptoms of syphilis may account for the difference, but this only takes us a step further back without solving the problem. These are points to which, it appears to me, the attention of the Section may be directed with advantage.

In the remarks which follow reference is made exclusively to that form of itching to which the term pruritus is usually restricted—that is, where itching is the only cutaneous symptom, apart from the lesions produced by scratching, and which I am in the habit of calling pruriginous eruptions. This, as Malcolm Morris observes, is a sensory neurosis caused by some disorder of the related nerves, independently of any source of irritation of the surface. Bronson has further elaborated this definition by stating that the disturbance is of the nature of a dysaesthesia, due to accumulated or obstructed nerve excitation with imperfect conduction of the generated force into correlated forms of nervous energy, while the scratching relieves itching by directing the excitation into freer channels of sensation. This view may not be generally accepted in its entirety, but at all events there can be no question that pruritus is the result of a direct, or perhaps sometimes of a reflex, disturbance of the cutaneous nervous filaments, and referable to the nerve centres.

It would be out of place before such an audience to deal exhaustively with the etiology of this distressing complaint, but a few of the more prominent causes may be referred to as types, especially as it is usually by attention to the general health that relief is to be expected.

The pruritus of advancing years is supposed by many to be due to "the structural changes to which the tissue of the skin, as well as that of most other organs, is subject,"² but a more potent cause is probably to be found in the sedentary habits and decline in the functional activity of the organs and tissues of the body of old people, with, as a consequence, impairment of nutrition and the circulation of impure and therefore irritating blood. The itching which often accompanies jaundice is doubtless due in great measure to the presence of the bile acids in the blood, but the fact that many cases of intense jaundice are free from it, while more moderate degrees of it are the source of severe pruritus, is not so easily explained, although it may be accounted for perhaps by the greater sensitiveness of the nervous apparatus of some persons or by slight differences in the composition of the bile which renders it more irritating in some cases.

Functional and organic diseases of the genito-urinary organs and pregnancy are well-known etiological factors in its production, while the gouty diathesis and derangements of the digestive organs are probably amongst the most frequent of all causes. In the latter case it is supposed by many that the irritation of the skin is of a reflex nature, although it may be contended with much greater show of reason that the products of imperfect digestion are direct irritants of the cutaneous nervous filaments.

It is now many years since a perusal of the classical lectures of Trousseau made me familiar with the connection subsisting between pruritus and diabetes mellitus. "When you are consulted," he wrote, "by women who are becoming elderly, for intense itching in and around the vulva, when, on examining the parts, you find there is eczema, and learn that it has come on irrespective of the menstrual periods, or of any leucorrhoeal discharge, and that the pain it occasions is so great as to prevent sleep, the probable existence of gly-

¹ In the Section of Dermatology at the Annual Meeting of the British Medical Association held in London, July-August, 1895.

cosuria will suggest itself.¹ This connection, though well established, is often unrecognised, because the relationship of the two is not so universally known as it ought to be, and because, in my experience at least, the pruritus often occurs in those who present few, if any, of the typical symptoms of diabetes; indeed it frequently happens that diabetes is not suspected until the onset of pruritus leads to an examination of the urine. This is well illustrated by one of my earlier experiences in 1876. I was requested by a professional friend to see with him a lady about 50 years of age on account of an intolerable itching between the labia, of long standing, accompanied by stinging and darting pain which prevented sleep, and made her life miserable. She was a healthy-looking, well-nourished woman, the skin was soft, the tongue clean, the appetite moderate, and she made no complaint of thirst. But, on testing the urine, it was found to have a specific gravity of 1.026, and to contain sugar in abundance. In this class of cases the pruritus is favoured by the lowered tone of the system induced by the diabetes, while the exciting cause, according to some, is the irritation of the saccharine urine, while others are of opinion that the cutaneous nerve endings are irritated by the saccharine impregnation of the blood.

Another form of pruritus of some interest is that which attacks some persons in cold climates during cold weather in autumn, winter, and spring, and which is apt to be an annual visitor, which Dühring has made us familiar with under the name *pruritus hiemalis*. According to Diakonoff² it consists primarily in an abnormal irritation of the cutaneous sensory nerves, which, in a reflex way, brings about a localised paralytic dilatation of the cutaneous capillaries, with a subsequent disturbance in the nutrition of the sensory nerves.

Finally the disease may be mental rather than physical. This is well illustrated by the case of a lady who consulted me on account of what she described as an intolerable irritation of the skin, which deprived her in great measure of sleep and made her life a burden to her. Two years before this she visited a deaf friend, who used a speaking trumpet. She put her mouth close to the mouthpiece of the trumpet, and from that moment she began to experience the abiding irritation for which she sought my advice. I never saw her again, but it is not improbable that her case ended in insanity.

Not infrequently the cause of the pruritus is involved in mystery, or that which produced it has passed away, while the irritation continues, owing to the cutaneous nerve filaments having, so to speak, contracted a bad habit.

It will be gathered, then, from what has been said, that, without denying the influence of reflex irritation in the production of this disorder in some cases, I am of opinion that most are dependent upon direct irritation of the nerve terminations in the epidermis.

Before entering upon the treatment of pruritus we must take care to satisfy ourselves of the accuracy of our diagnosis, so as to exclude that numerous class of cases in which the itching is but a symptom of other disorders, such as urticaria, phthiriasis, and scabies. Having done so, we must, in the next place, make a thorough examination of the patient, in the light of the etiological factors, which have just been touched upon, and endeavour to correct any derangement of the general health which may be present. But sometimes we are unable to find any satisfactory explanation of the phenomenon, or the cause may be incapable of removal, or it may be got rid of, and yet the pruritus persists, in which case it must be treated empirically.

It is unnecessary to dwell upon the local treatment, for, although temporary relief may be afforded by the use of the many well-known antipruritic—especially spirituous—lotions and ointments and sedative applications, they have too often little permanent influence upon the disorder, except of course in those cases which are dependent upon some local cause—such as hemorrhoids, ascariasis, stricture of the urethra, etc.—and which must be got rid of.

In some cases, especially if there is any suspicion of nervous or nutritive debility, nerve tonics—such as phos-

phorus, arsenic, or strychnine, alone or in combination—may be tried, the last two preferably by subcutaneous injection. Dr. Bulkley, of New York, speaks highly of tincture of gelsemium in doses of 10 minims, repeated in the same or in a larger dose, every half hour, or until a drachm is taken within two hours; and of tincture of cannabis in doses of 10 to 30 minims thrice daily after food, and well diluted; while Hebra recommended the internal administration of carbolic acid, to the extent of 10 to 16 grains daily.

For my own part, the best results have been obtained by the administration of atropine, or one of the coal tar derivatives, and by the use of electricity. Atropine is best given subcutaneously, beginning with $\frac{1}{10}$ grain at night, the dose being cautiously increased so long as the physiological effects of the drug are not pronounced, and so long as the pruritus is not completely subdued. Of the coal tar derivatives, antipyrin and phenacetin are specially to be recommended, particularly the former, the initial dose being 10 grains. But here, again, the dose must be steadily increased, and it is surprising what large doses may be not only tolerated, but taken with advantage, as I have shown with regard to antipyrin in connection with a somewhat allied disorder—chorea.³

One of these remedies may be often combined with great advantage with electricity, or the latter may be used alone. It may be employed in various ways, either in the shape of the electric bath or by the application of the continuous current of electricity of moderate strength for ten minutes night and morning, and when the itching is troublesome, one sponge (the positive pole) being applied to the top, and the other to the bottom, of the spine.

Treatment carried out upon the lines which have been indicated is calculated to yield excellent results in a large proportion of the cases; at all events, in my own experience, it has usually proved successful.

II.—H. A. G. BROOKE, B.A., M.B.Lond.,

Lecturer on Skin Diseases Owens College, Manchester; Physician to the Manchester and Salford Hospital for Skin Diseases.

PRURITUS IN ITS RELATION TO DISEASES OF THE SKIN.

To attempt to give anything like a complete account of so large a subject as that of pruritus in the short space at my disposal would be an impossible task, for the affection to which the term is applied occurs in so many and such various ways, and is often so mysterious and insidious in its origin, that any attempt to make a thorough investigation of the subject would pass far beyond the limits of a brief address. In order, therefore, to narrow the field, I would wish to make a general grouping of the various manifestations of pruritus as they are most commonly observed, and thus try to gain an insight into its etiological factors and some basis for a rational line of treatment for each individual case, often a difficult, but always an indispensable preliminary task.

And first, with regard to the term pruritus. It is generally understood to denote all forms of itching, whatever their origin, and in that sense I shall make use of it here, although I am fully cognisant that in most works on dermatology the term pruritus, or pruritus cutaneus, is reserved for those cases in which the itching is the only or, at any rate, the primary symptom. The old term *prurigo* has now become so closely associated with the special affection to which Hebra applied it that its use is almost equivocal in any other sense. Besnier and Brocq have rightly objected to this limitation of its meaning, for the prurigo of Hebra is, although a well-characterised disease, not an isolated pathological entity, but simply the exaggerated expression of a whole group of allied affections which we shall have to consider more in detail later on. They apply the term prurigo to those forms of pruritus which are followed by the development of secondary lesions of the skin due to scratching, such as wheals, papules, and eczematous manifestations. The distinction is a useful one, since there are some forms of essential pruritus which are neither accompanied nor followed by the development of any secondary lesions, and it would tend greatly to clear away a confusion of long standing if it were definitely agreed that the terms pruritus and prurigo, when used without any

³ On the Use of Antipyrin in Large Doses, BRITISH MEDICAL JOURNAL, December 1st, 1894, p. 1227.

adjectival qualification, no more serve to distinguish any one separate disease than do such terms as lichen and erythema.

The intensity of the itching sensation varies, as we know, enormously. It may be simply momentary, sometimes a mere local titillation which hardly requires relief, at other times coming on severely in fits which compel some spontaneous attempt at relief, and in some few cases it is actually continuous and without any remission. At its worst the sensation comes in paroxysms of such intensity that the patient, losing all self-control, tears and scratches, with almost maniacal fury, until he has diverted the irritation into actual pain.

Bronson, of New York, in some excellent and very thoughtful articles, has sought to explain the phenomena of ordinary itching by considering them as perversions of the sense of touch, and the more violent outbreaks by comparing them with the physiological evolution of the sexual orgasm. In his opinion the sensation of itching is a dysæsthesia of the nerves of the sense of touch. These nerves are probably those which Pflüger and Unna have shown to penetrate among the lower epithelial layers of cells; for without epithelium, as we see on the surface of a wound, there is no itching; it begins as the epithelium is being restored. Itching, according to Bronson, is a distortion of the sense of touch, as the sexual feeling is a modification of the sense of touch; and the one may be excited abnormally by friction, as the other is normally, until a crisis of sensual excitement is produced. In the one case the feeling is limited to a specially modified part of the cuticle; in the other it is spread over the whole surface indiscriminately. The friction which is instinctively resorted to when the itching commences is continued until the pleasant sensation is exhausted, or until scratching has produced the pain which is antithetic to every pruritus. It is the conversion of a vague weakly form of nerve action into one of the more ordinary types, either of pain or exhaustion.

This paresthesia or dysæsthesia of the cutaneous nerves may originate either in the over-excitability or in the debility of the nerve action; but our knowledge of the physiology of the methods of nerve action is too limited as yet to allow us to explain why certain individuals are attacked with pruritus while others, under apparently the same conditions, remain free. Nor is the problem simplified by observing the very varied nature of the causes which may give rise to pruritic irritation. For example, the tickling sensation which we all feel when a fly walks over our skin may be imitated either by the action of a poison circulating in the blood, by a purely mental suggestion, or by commencing nerve degeneration, by some modifications in the structure of the skin such as are found in purely local disease, or even in the physiological process of the healing of surface wounds.

Interesting and suggestive as speculations on the essential nature of pruritus may be, it is of more practical importance to us here to study the various conditions under which the sensation of pruritus may be found; for it is hardly necessary to repeat that, without having some clue as to what constitutes the exciting agent in each particular case, our treatment would inevitably resolve itself into little more than the treatment of symptoms.

With the intention of rendering this preliminary investigation somewhat easier, I have attempted to draw up a simple scheme of the different conditions which give rise to the sensation of itching. It is not an ideal classification, because there is some overlapping of its divisions; but this is a fault common to all dermatological schemata, in which no constant basis of classification can be upheld, the principle of division being partly utilitarian, partly anatomical, partly pathological, according as our knowledge or convenience prevails.

In the first place, we may make a broad division of the different cases of pruritus into those which are brought about by the action of external causes and those which owe their origin to purely internal conditions, either of the body or of the skin itself. Some of the divisions seem to be quite clear and distinct, but others, probably the majority, to belong to both classes, the preponderance lying in one more than in the other.

In the *internal group* are included (1) those cases of pruritus which have a neurotic origin, and these may be subdivided

into two subgroups, according as (a) the primary excitant of the itching is purely nervous or (b) is secondary to the irritation arising from neurotic skin affections or is due to reflex nerve irritation from other causes. (a) First among the purely nervous affections we meet with the class of pruriginous diseases which have been so laboriously studied by the French dermatologists, especially Brocq, Besnier, Vidal and Leloir, in which the pruritus is essentially the primary disease. I will not attempt any critical examination of the views of these authors as to the *neurodermites*, the diseases which they regard as being of purely neurotic origin, but I am far from agreeing with all the statements and deductions made by several of them. Brocq, for instance, excellent clinician as he is, in some of his articles on this subject details cases of supposed 'primary pruriginous neurodermatitis' which seem to me, from his descriptions, to be distinct examples of primary epidermic diseases (such as seborrhœa) in which the lesions, although symmetrical, had only become so secondarily; and others we should consider to be due to hæmitic irritants rather than to purely nervous conditions. He and Jacquet have, however, certainly done great service by demonstrating that a primary pruritus may bring about through the action of the constant scratching to which it gives rise, that more or less indurated, papular, brown or bistrous-coloured condition of the skin to which he has applied the term "lichenification." This form of lesion, even when secondary to the pure nervous pruritus, has hitherto been regarded as a chronic eczema or lichen, and looked upon as a local distinct disease rather than a mere secondary symptom of the general nerve irritability to which it owes its origin. All the forms of primary nerve pruritus do not lead to the development of this lichenification. In some the skin does not seem disposed at all, or only very slightly, to undergo this change, even when under the influence of constant scratching. There are some of these forms, of which senile pruritus is the best known, in which such secondary lesions are characteristically absent. They have been long designated as "pruritus sine prurigne," a pruritus unattended by any manifest alterations of the skin either primary or secondary. They are by no means necessarily confined to the aged, nor are they always continuous in action nor spread over the whole body. They may occur in young people, as in a case reported by Rons, of a child of 6 years old, in which the pruritus had come on at the age of 2, after an intestinal catarrh, and continued unintermittently for four years without provoking the development of any skin lesions whatever. Or they may be confined to circumscribed areas such as the face, hands, tongue, anus, or genitals. Of these local varieties of purely neurotic pruritus those of the anus and of the genitals are best known, owing to their disastrous effect on the patient, and to the, at times, almost insuperable difficulty in coping with them. But cases are put under this heading which, though undoubtedly of nervous origin, cannot rightly be considered as belonging to this class. I do not refer to the great majority of the cases of anogenital pruritus, which are, in my opinion, of primary external origin (and very generally due to seborrhœic infection), and of which the appropriate local applications form the most essential part of the treatment, but I am speaking of those cases in which the skin, though to all appearances normal, is found to present one or more hyperæsthetic points from which the itching sensation radiates whenever they are irritated by change of temperature, alteration of blood pressure, or by the presence of certain toxic substances in the blood, produced either in the body, or derived from food stuffs. Such cases differ from the truly neurotic pruritus, in that the destruction of one or two hyperæsthetic points, for example, with the galvanocautery, will put an end to the whole of the symptoms, whereas in the latter the total removal of the entire nerve apparatus may be necessary in order to finally remove the itching. It is in the class of cases in which the itching is accompanied by the development of papular eruptions that I think Brocq's classification most open to dispute. To these affections he gives the name of "primitive lichenifications," and asserts that in France they are exceedingly common. There is no doubt not only that itching may precede the development of actual lesions of the skin, but that the sequence may occur in highly nervous people, or as the result apparently of nervous shock and over-

strain; but it is not justifiable to quote cases, as he has done, as examples of primary neurotic pruriginous disease unless the pruritus is known to have preceded the lesions, and that these are such as are not liable to be confused with the lesions of local diseases, like scab, and removable by antiparasitic remedies. The point is one of importance from a practical view, for the prognosis and the whole course of treatment may depend on the fact as to whether the local lesions are the cause of the itching, or the nervous irritation is responsible for the development of the itching and the consequent development of lesions by scratching.

Into this class come other affections in which the itching precedes the outbreak of any eruption, some eczemas, and those forms of "acute lichen simplex" which Vidal and Brocq have regarded as urticarial in character, but which are more generally, and perhaps rightly, included under the heading of papular eczema. The prurigo of Hebra, which shows the close connection existing between the primary neurotic pruritus and the later development of urticarial, papular, and eczematous lesions is the most comprehensive and clearly individualised member of the family. Besnier has grouped under the generic heading of "diathetic prurigo" a whole family of these chronic, polymorphic, pruriginous dermatites, which recur in successive crops and take on a predominantly eczematoid-lichenoid character. "Their first and always prevailing symptom," he says, "is pruritus, pruritus which remits, exacerbates, comes on in nocturnal paroxysms, and has regular seasons of remission and exacerbation. Very commonly it appears in early infancy or youth, it may be later, but it commences always in an insidious and masked form. An absolutely fundamental characteristic is that none of the lesions which accompany it, or which it provokes, are specific in character. In the early stage they may be any one of the numerous varieties of infantile erythemas, urticarias, or pseudo-lichen, or some form of lichenisation or eczematization of the skin. Later, when the disease has become established, some of these forms of lesion may be at times observed, but they will be especially the lichenisations in the form of papules, or in patches, or covering large surfaces, and at the moment of the paroxysms it will be eczematization under the most varied forms of eczema figuratum, diffusum, impetiginosum, etc. It is a veritable itching diathesis with multiform lesions, none of which by themselves serve to designate the disease; it is a prurigo in the true sense of the word, a diathetic prurigo." In many of these cases the morbid action may leave the skin, momentarily or finally, to localise itself in the viscera, setting up there either emphysema or bronchial asthma, or hay fever, or—though less frequently—gastro-intestinal troubles. When once this itching diathesis is established treatment is, in Besnier's opinion, of little avail; "it may become attenuated or extinguished, it may cure itself or exhaust itself, but we can never say that we have cured it."

Instances of this affection, with its alternations or simultaneous attacks of itching and scratching and of pulmonary or abdominal disorder, are familiar to us all; but I think that most of us would be loth to subscribe to Besnier's pessimistic prognosis, for in my experience much can be done under favourable external conditions to relieve and even to rid these sufferers of their grievous burden. The main point, however, is the recognition of a pruriginous diathesis—for want of a better word—which sometimes finds its outlet in the epidermic nerves, where it causes incessant itching and subsequent alterations in the skin, with possible metastases in the internal organs. The condition may be hereditary, and may even show distinct signs of stigmata.

In this group of neurotic itching disease must also be included the pruriginous eruptions of papular or vesicular pemphigoid form, which were associated together by Tilbury Fox under the name of "hydra herpetiforme" and by Darbinger as "dermatitis herpetiformis." Their asymmetrical character and the fact that they may be ushered in by attacks of violent itching show that the nervous system is intensely implicated; but the manner in which—like the eruptions of erythema multiforme—the outbreaks may be brought on by the ingestion of certain articles of diet, by constipation, or dyspepsia, proves that their origin is not always exclusively nervous.

Purely neurotic urticaria is a well recognised affection,

and numerous instances are known in which a mere thought is sufficient to precipitate an outbreak of wheals with the accompanying intense pruritus.

Itching is also a premonitory symptom of some of the severer diseases of the nervous system, and Leloir has catalogued several of these symptomatic prurigos under the title "dermatonévroses indicatrices." They are not, I am told by neurologists, very common as prodromata.

Lastly we have to place under this heading those cases which Crocker has well spoken of as "pruritus mentis." Those who are afflicted with this complaint devote their whole time to scratching; they are possessed with the idea that they are suffering from the ravages of insects, or that grains of sand or what not are lying under their skin, and the constant irritation which this thought alone produces is so great that they can think of nothing else and talk of nothing else, and they do nothing else but scratch. No amount of reasoning, and naturally no amount of treatment, is of any avail. I have tried the effect of hypnotic suggestion on one such patient, but without the slightest beneficial result. The condition is really one of monomania, and constitutes a very hopeless form of insanity.

The purely nervous reflex form of itching occurs from time to time in everyone. Even when we are perfectly free from any lesions of the skin, a slight itching may be noticed in one part of the body which is almost immediately followed by a similar sensation in some one or more spots, often far removed from each other. The exciting cause is not easy to determine, for the sensation is mostly only momentary; it may possibly be merely some passing local irritation. Under any conditions it does not amount to a pathological state, and is only interesting as showing over what extensive surfaces a minute and purely local pruritus may be reflected.

(b) The cases of secondary neurotic pruritus may be conveniently divided into two classes, according as they are connected with disease of other organs than the skin, or are the result of some abnormal irritation of a mechanical or physical character. In the first group come those instances of more or less general itching which accompany or foreshadow the development of serious gastric or intestinal disease, such as carcinoma, or of various morbid states of the uterus. It might readily be supposed that in both these instances, the pruritus betokened some form of systemic poisoning, but the occurrence of similar itching in normal pregnancy and during normal menstruation, show the possibility of a purely reflex nervous origin. Some of the women whom I have seen suffering from herpes gestationis or post gestationem, notoriously a very pruritic disease, have been otherwise in perfectly good health, and all have given birth to healthy children.

The presence of tapeworms in the bowels may give rise by mechanical irritation to the most intense general pruritus, which ceases at once when they are removed. Some foods apparently act in the same way; oatmeal porridge, for example, will cause great irritation of the skin in certain people if prepared by the ordinary quick method, but is quite innocuous if boiled until all the gritty particles have disappeared. The reflected itching at the end of the penis in the case of stone in the bladder, and to the nose when ascarides are present in the rectum, are very familiar instances of the same character.

Itching from the action of cold or heat upon the skin probably comes under this same heading, since it is by no means absolutely necessary that the change of temperature should act directly upon the part attacked. Thus pruritus hiemalis, which by preference affects the thigh, sometimes begins to make itself felt before the patients have left their beds in the morning. Two very observant men have assured me that they could detect the early frosts of winter before leaving their beds or raising the blinds, by the peculiar irritability of their skins. As another variety of direct reflex from cold I may cite the case of an apparently healthy girl who invariably suffers from urticaria if she wets her face with cold water, and the itching and wheals are not always confined to the face, but extend from there over a large area of the body.

2. A very distinct, and in the minor degrees of development very frequent, class of cases are those in which pruritus is brought on by the irritation of toxic substances which have

been produced in the body, and have been disseminated by the blood current. The most familiar instances are presented by the itching found in connection with diabetes, gout, rheumatism, kidney disease, and jaundice. It is usually slight, and not confined to any particular part of the body, but we meet with cases in which it is general, others in which it is quite local, and in some it is very persistent. In *icterus* the itching may precede the deposition of bile pigment in the skin, and is not therefore, as has been asserted, due to the deposit and direct irritation of the bile products themselves. Pruritus *an*i is sometimes connected with gout, and I have seen more than one case of extensive itching at once and completely removed by the onset of acute podagra. General itching of a not very pronounced character is one of the many symptoms of the sluggish action of the liver, which Marchison named *lithemia*. The pruritus which accompanies constipation and faulty digestion, and is sometimes of an urticarial character, is probably of the same nature, and due to the absorption of toxins, the products of imperfect metabolism and of fermentative processes in the intestinal canal. Slight cases of this kind are familiar to the laity, by whom they are attributed to "overheating of the blood," and are often quite effectually treated by some household laxatives, cholagogues and alkaline diuretics, with a lowered diet.

The urticarial pruritus of infants and children is, I am convinced, very frequently associated with the presence of rachitis and the malassimilation of food which accompanies it, due, apparently, to dilatation of the stomach. Antirachitic treatment will certainly often relieve in such cases when all the internal empirical remedies fail.

These toxic states of the blood often cause the exaggeration of itching which has been originally excited by a local disease of the skin, and their treatment is an important item in the treatment of the local trouble. Bessier thinks that many cases of senile itching, in where there are no local lesions and which would therefore be regarded as examples of pruritus *senilis*, are due to defective kidney action rather than to defective action or degeneration of the nerves, and incompetent action of the heart may be an assisting factor, if it is not the primary cause, of much itching in old people.

3. In all these instances the occurrence of itching is due to some idiosyncrasy on the part of the individual sufferer, for it only occurs in a small percentage of those who are affected. This is also true of the itching which is caused by certain foods and drugs. Many patients complain of an irritability of the skin which they have found by experience to follow on the indulgence in some special articles of food. The urticarial itching which results from the ingestion of shellfish is the most familiar example; but others complain of vague itchiness after eating cheese, or drinking tea or coffee, or alcohol, and it is always advisable to investigate the existence of such peculiarities, or to remember the possibility of their presence, in dealing with cases of pruritus of unknown origin. Some drug-give rise to itching when introduced into the system; it is not an infrequent effect of opium, and also occasionally results from the action of belladonna, mercury, and iodoform. When an erythematous eruption accompanies or precedes the onset, the action of the drug is probably directed on to the nerve centres supplying the affected areas, but where no eruption is discoverable it may be due to the circulation of the poison in the blood and its direct action on the terminal nerves of the skin.

4. The influence of increased blood pressure in causing itching is seemingly due to the mechanical pressure on the nerves, for the itching of hemorrhoids, when uncomplicated, disappears as soon as the pressure is removed. The pruritus of pregnancy, when localised to the ano-genital region, is probably due in like manner to the engorgement of the pelvic plexuses of veins.

5. The skin of otherwise healthy people is, at times, disposed to itch annoyingly on account of its abnormal lack of lubrication. Of this circumstance two explanations have been offered, namely, that it is caused by the formation of minute fissures in the outer epidermis, and partial exposure of the epithelial nerve endings, or that it is owing to the stoppage of the excretory functions of the skin, and consequent irritation by the uneliminated waste products from the blood. The enormous relief which is afforded by the action

of sudorifics, such as *Jaborandi*, vapour baths, and impermeable dressings might be explained by either supposition; but the localised itching in xerodermic patches would point rather to the partial exposure of the nerves as being the more important factor, and those who sweat very slightly complain, as a rule, of the annoyance of the burning rather than of the itching of the dry skin. Indeed, in opposition to the view so dear to the general public, the eliminative function of the skin seems to be replaced very perfectly by the normal kidney, and it is only in such conditions as uræmia and senile atrophy that we find the incapability of elimination by the kidney causing irritability in the external organ.

The various external causes which provoke the sensation of itching may be roughly divided into three headings, namely, local skin diseases, epizootic parasites, and irritants of a physical or chemical nature; but, except in regard to the latter division, it is often difficult to make an absolute distinction between their method of action.

In the consideration of this group the question at once arises, and a very important question from a therapeutic point of view, to what extent certain diseases of which itching is a prominent symptom are local in origin, and what extent they, and therefore the itching, are due to general systemic causes. In ichthyotic skins the mode of origin of the pruritus is obvious, for the patient may be in perfect health, and the skin free from every sign of inflammation, and under the action of a simple emollient, which restores sufficient of its elasticity to prevent it from cracking, the itching may completely disappear. But the case is quite different with such affections as lichen planus, papular seborrhoea, psoriasis, and some of the acute eczematous eruptions, which may come on suddenly in patients who are in otherwise good health, and which are usually accompanied by an amount of itching which is proportional to the amount of inflammation which they develop, and to the rapidity of their extension.

In common with many others I do not regard eczema as a disease *per se*, but as a pathological process which is capable of being brought about by many causes, and I think it will be hardly disputed that a considerable number of cases of even acute general attacks of eczema are of parasitic origin. The predisposing cause of their rapid extension is often some failure of health, most frequently nerve prostration, which induces an excessive irritability of nerve sensation and instability of the tonic spasm of vaso-motor nerves, with a corresponding liability to rapid flushing of the inflamed areas of skin. In other cases, however, this neurosthenic condition is gradually induced in previously healthy people by the continued irritation—it may be of only one or two eczematous areas—and the loss of rest which results from the constantly-recurring itching and consequent scratching to which they give rise. It is possible that in such cases we have the analogy of what happens in affections of undoubtedly local origin. In scabies, for example, the itching spreads far outside the area occupied by the *acarus* itself. Experiments have been made by inserting a female insect into the skin, and covering it tightly with a watchglass so as to prevent its migration, and it has been found that after it had established itself, an intense spasmodic itching developed in parts of the body quite remote from the burrow, and due apparently to the absorption of some substance secreted by the insect. But the irritating substance need not necessarily be of organic nature, for Neisser records a case which from its severity will serve as an example of a well-recognised class—of a medical man who suffered from sudden attacks of apparently typical acute general eczema with excessive itching. It was regarded by all his colleagues as being distinctly constitutional, and was treated as such without success until he himself found accidentally that he could precipitate an outbreak at any time by the application of the smallest quantity of iodoform to the skin. It is now well known that some people have an idiosyncrasy with regard to certain plants of the *primula* family; a mere touch of the skin during the summer months against the leaves of the plant suffices to produce an intensely irritable papular erythematous eruption which has the same peculiarity as that of iodoform, that it is auto-inoculable on to other parts of the body by contact or by scratching. It tends in some of the victims to become eczematous in character, and some very marked cases of acute symmetrical

eczema I have traced back to the action of a mere casual touch on the leaves of a plant of this order.

This mode of spreading of acute eruptions, and especially pruritic eruptions, from a single focus of known external origin, cannot but suggest that the violent extension of some eczemas of parasitic origin, or of eczemas which have become parasitic, as judged by the gyrate or polycyclic outlines of the patches, may be due to the absorption and diffusion of some substances produced by the parasites under conditions of body analogous to those which give rise to the acquired idiosyncrasy for iodoform or primula poisoning. What these conditions are it is often impossible to decide, but the suspicion of the existence of a focus or foci on the skin from which irritating material is being diffused, is a valuable working hypothesis which may prevent a general eczematous attack from being regarded and treated as purely systemic in character, whilst the true source of the irritation is allowed to spread. It certainly also suggests one explanation of the extraordinary fact that so large a number of the anti-pruritic remedies are of the disinfectant and bactericide class.

The purely fungoid diseases of the skin, such as tinea trichophyton and pityriasis versicolor rarely cause much itching. The latter, however, may do so exceptionally. I remember the case of an old medical man who had suffered from such intense and increasing pruritus for two years that his mental condition was becoming affected. I found a well-marked but not excessive infiltration of the cuticle with microsporon ferfur, and when this was removed he was, within a fortnight, completely freed from every unpleasant sensation.

The action of the epizootic parasites in producing itching needs no more than a mention; some of them, such as the pulex, cimex, and mosquito irritate by the injection of secretions; others, as the lice, seemingly by simply biting or crawling on the skin, while the acarus scabiei probably acts in both ways. One curious feature about the bites and stings of these insects is the extraordinary amount of toleration which may be established in those who have become habituated to their attacks. The skin may be found thickly covered with fleabites, for example, without showing any signs of scratching, and the patients deny the occurrence of any itching sensations.

Of the physical causes which induce itching by their direct action on the skin, none is more familiar than the influence of sudden changes of temperature. Many pruriginous skin affections are incited to activity by sudden exposure to cold, and hypersensitive, though otherwise seemingly normal, skins are inclined to slight itchiness when the clothes are quickly removed. The removal of the pressure of the clothes has undoubtedly some influence in increasing the sensation, but it is not so apt to occur if the skin is cool at the time of removal, and it can hardly be the difference of pressure which rouses pruritic affections of the anus to activity immediately after undressing. It appears to be rapid alterations in the blood pressure induced by these quick changes of temperature which are the chief excitants of the itching, for it is almost always confined at first to parts which are in a condition of more or less inflammation, acute or chronic, and which are, therefore, unable to accommodate themselves to the alteration of pressure. The power of very hot water to allay pruritus may perhaps be explained by its action in overcoming this impediment and reducing the increased blood tension. Variations in the position of the body seem distinctly to affect the amount of pruritus, for patients will often complain—especially those who are suffering from the acuter inflammatory forms of pruritic disease—that the itching and burning will increase during the daytime, when they are in ordinary dress, if they assume the recumbent position, and I hardly see how this fact is explicable except on the assumption that the change of position increases the blood pressure.

Except indirectly, through the intermediation of some lesion, such as dermatitis, perionies, sudaminous and miliarial rashes, heat and cold rarely produce itching by their direct local action on the skin. Pruritus hiemalis and E. aestivalis I have regarded as being caused by reflex nerve action—a view which is further supported by the symmetrical angioneurotic character of the lesions which often accompany them.

The actinic rays of the sun act, so far as the production of pruritus is concerned, with great power on some individuals, but always indirectly through the lesions which they produce. The affections of the "summer prurigo" class, which are directly due to the action of light, are intensely pruriginous, and lead in time, by the incessant scratching, to a degree of lichenification and eczematization of the hands and face, which closely resembles one of the elephantiasis forms of chronic eczema. Even a diffused daylight is sufficient to excite, in some people, an intense urticarial pruritus on the exposed surfaces. One of the worst cases which I have seen was that of a lady whose hand and forearm, which she bared to show me, were covered thickly in two minutes with small intensely irritable urticarial wheals.

Of the action of drugs and plant poisons we have spoken already. They excite irritation externally either by applying their poison at the ends of sharp-pointed hairs, as in the primula and nettle, or, more indirectly, by gradual penetration to the nerve terminals. The lesions which accompany them are very seldom sufficiently characteristic to be pathognomonic, and the diagnosis has often to be deduced from a number of inquiries as to the occupations and pursuits of the patients. This is all the more necessary as the pruritus which is caused in this way is often of great severity, and increases in degree if the contact with the offending agent is continued.

The simple irritability of skin produced by rough under-clothing, though unimportant pathologically, is of great importance from a therapeutic point of view, and the substitution of silk for coarse flannel often makes all the difference between comfort and discomfort to those whose skins are naturally sensitive and irritable, or who have become so through the presence of some pruritic affection. The irritation is caused obviously by the tickling of the skin by the ends of coarse woollen hairs. What can be done by a purely mechanical irritation of this kind is best seen in the intolerable itching which results from the application to the skin of the fine dried spicular hairs of a leguminous plant, which are known as cow-hage, or cow-itch.

I am not going to attempt now to enter into any details as to the treatment of pruritus. That has been done already by my predecessor, and will no doubt be taken up by the members present. My object has been to try to make a rapid survey of the various conditions in which pruritus may occur, so as to aid in the recognition of its cause in individual instances. The pruritus is, it is true, in the great majority of patients, merely a symptom of disease, but it is generally the symptom from which they are most desirous of being relieved, and it is often the annoyance of the pruritus rather than the disease itself which urges them to seek our help.

III.—A. S. MYRTLE, M.D. Edin., etc.,

Harrington.

Dr. MYRTLE insisted on the difficulties of treatment in cases of pruritus. In vulvar and anal cases he had found the free use of potassa fusa, gr. xv-xl ad ʒj, most valuable.

IV.—HENRY WALDO, M.D. Aberd., M.R.C.P. Lond.,

Physician to the Bristol Royal Infirmary.

Dr. WALDO pointed out that a plan of treatment suggested by the President of the Section some years ago had not been mentioned, namely, counter-irritation of the vasomotor centres by means of the mustard leaf applied over the spinal cord. He had found this mode of treatment most successful in some troublesome cases. With regard to osteo-arthritic pruritus, salicylate of soda was useful, alone or combined with arsenic.

V.—G. G. STOPFORD TAYLOR, M.D. Durh.,

Hon. Surgeon, Liverpool Hospital for Cancer and Skin Disease.

Dr. STOPFORD TAYLOR said that constitutional remedies as a rule were not of much use, although gouty, rheumatic or dyspeptic symptoms must always be attended to. Pruritus hiemalis was best relieved by exercise and soothing applications, such as ointments of glycerine, of lead, etc., and cotton or silk underclothing. The daily bath should be interdicted. For pruritus ani and scroti the application of spirituous remedies and the separation of opposing surfaces of skin were

indispensable. Baths of weak solutions of liq. carbonis deterg. were also most grateful to the patient. He had seen many cases occur in those who engaged in polo and cycling.

VI.—F. H. BARNETT, M.D., F.R.C.S., Eng.,
Liverpool.

Dr. Barnett considered that local applications were most important, especially in those cases where pruritus alone was present, and there was no skin lesion that could explain it. He extolled the application of blisters over the spinal region which supplied the pruritic area. After having tried several local remedies—resorcin, menthol, salicylic acid in ointment and paste form—he had obtained great relief by thoroughly rubbing into the affected area hot olive oil containing 2 per cent. of carbolic oil, for five minutes night and morning.

VII.—ELIZABETH GARRETT ANDERSON, M.D., Paris,
Physician, New Hospital for Women, London.

Mrs. GARRETT ANDERSON said that in treating neurotic pruritus in women, and men leading feminine lives, she had found that an increase in the quantity of food which suited the patient gave good results. Rest, especially before meals, was important. Bathing was ill-borne in these cases. She also recommended complete silk underclothing. Cod liver oil should be added to the food if necessary.

PROFESSOR McCALL ANDERSON'S REPLY.

In his reply, Dr. McCall Anderson said that the treatment of the cause was the important point, but he did not undervalue local treatment. He considered that the good influence of Harrogate, for example, was not due to the baths, but to the diet, and also to the healthiness of the surroundings. He agreed with Mrs. Anderson's remarks as to the importance of keeping up the nutrition.

AFFECTIONS OF THE SKIN OCCURRING IN THE COURSE OF BRIGHT'S DISEASE.¹

By P. H. FYE-SMITH, M.D., F.R.S.,
Physician to Guy's Hospital.

THE only cutaneous disorder hitherto generally recognised as occurring in Bright's disease is the erythema leve of Willan. His original description in 1803² was followed by Bateman and subsequent writers. He notices its uniformly smooth and shiny surface, the red patches becoming confluent, and its association with anasarca. He describes it, however, as occurring both in young and old patients, particularly in those who are intemperate, and as not always accompanied by dropsy. He also observes that the apparently slight inflammation may end in local gangrene.

Erythema leve is a superficial dermatitis which owes its characteristic smooth, shiny appearance to the fact that it appears on surfaces made thin by dropsy. It may be the result of local irritation from pressure, and the term has been applied to the first stage of a bed sore. But as it appears on the dropsical limbs there is no evidence of external irritation in its locality or spread, and it is seldom seen in the anasarca of cardiac or hepatic disease. It is also quite distinct from the local recurrent erythematous or erysipelatous dermatitis which leads to elephantiasis of the legs. So restricted, the term may still be used to describe the inflammatory blush which sometimes appears on the legs and thighs swollen by renal dropsy. In its pathology it should, however, be separated from other forms of true erythema—E. multiforme, E. iris, E. bulbosum, E. nodosum, and urticaria—and regarded as a dermatitis readily excited on a dropsical skin, just as pleurisy, inflammatory oedema of the lungs, and sometimes inflammation of the pericardium, the larynx, and the peritoneum are observed in Bright's disease. There are, however, other forms of dermatitis which not infrequently occur in the course of chronic Bright's disease:

1. There is a bright red diffused rash which appears chiefly

on the trunk, less extensively on the neck, arms, and thighs, and very seldom on the face, hands, or feet. It is distinguished from the somewhat similar rash produced by natural or artificial diaphoresis, by its locality, by the absence of sudamina, and by its appearing when no hot air baths, or other means have been used to produce sweating, and when the skin is harsh and dry. It does not, as a rule, either itch or smart, and only lasts a few days. I have most often seen this rash in cases of chronic tubal nephritis.

2. There is a papular eruption with large discrete rather dark red pimples seated on a dry, rough, and sometimes scaly surface. This I have more often seen on the outer side of the thighs and legs, the shoulders and extensor surface of the forearms, but it also may affect the loins and the abdomen. I have never seen it on the face or on the hands and feet.

3. Apart from the mere coincidence of eczema with Bright's disease, there may be observed in some cases a moist dermatitis resembling eczema in its respect, but occupying the arms or the legs, without affecting the flexures of the joints, the face or the ears, without the irritation commonly present, and without having previously appeared.

4. On two occasions I have seen a very extensive and profuse dermatitis closely resembling the universal exfoliative dermatitis of Wilson, very red, very scaly, occupying the scalp, palms, soles, and genitals, as well as the trunk, face, and limbs. It has come on after the symptoms of Bright's disease have appeared, in cases of chronic interstitial nephritis, with little dropsy, and cardio-vascular changes already apparent.

Different as these forms of dermatitis are in their anatomy, they have certain common characters apart from their occurring in patients suffering from Bright's disease. They are superficial, and leave no trace behind when they disappear or after death. They run an acute or subacute, not a chronic, course, and seldom recur after they have disappeared. They are never pustular. They are occasionally purpuric, but this is rare, offering a contrast with the hemorrhagic erythema of rheumatism and erythema nodosum. The subjective symptoms are usually slight. With respect to prognosis, they usually occur in the later stages of the renal disease, and therefore may be not infrequently present at the time of death. But they often disappear long before this, and their appearance does not coincide with any special aggravation of the other symptoms. As to their pathology, I am not inclined to connect them with uremia except by a natural coincidence, for we constantly see this condition in its most characteristic and fatal form without any cutaneous eruption, and each of the forms of dermatitis I have described has been seen where there were no other symptoms of uremia. Rather, I think, should these inflammations of the skin be associated pathologically with the retinitis, the serous inflammations, and the pulmonary oedema to which patients with Bright's disease are liable. With respect to the form of renal disease with which they are associated, I do not remember seeing any of them in the acute cases of nephritis with dropsy, either in children or adults; nor in cases of lardaceous disease of the kidneys. They have either occurred in the later stages of chronic tubal nephritis, or at any stage in the course of chronic granular degeneration with shrinking of the renal cortex.

The treatment I have found useful when local discomfort has called for it has been entirely external, and the vehicle an ointment rather than a lotion. Carbonate of lead, oxide of zinc, calamine or blamuth, have appeared to be the most useful applications, and sometimes immersion with olive oil or vaseline has been more efficient than any more active treatment.

In conclusion, I would remark that none of these affections (except erythema leve) are common, and my chief object in drawing attention to the subject is to elicit the experience of those who, I doubt not, will be able to fill up and perhaps to correct these imperfect outlines.

I must, however, particularly refer to a valuable paper by Dr. Le Comber Lancaster, which was read before the Clinical Society.³ It had escaped my notice until the above account had been drawn up, and I have not modified any of the statements which differ from those made by Dr. Lancaster, because

¹ Read at the Section of Dermatology and Syphilis at the Meeting of the British Medical Association held at Liverpool, July 4-9, 1895.

² *Medicinal Transactions*, vol. 1, p. 423.

³ *Transactions*, vol. xxv, p. 49, 1895.

by comparing our individual experience we shall best arrive at just clinical and pathological conclusions.

Dr. RADCLIFFE CROCKER, President of the Section, insisted on the importance of drawing attention to forms of dermatitis due to disease of the internal organs. In his experience he differed from Dr. Pye-Smith as to prognosis, which was gloomy in advanced cases of Bright's disease. He agreed with Dr. Le Cronier Lancaster.

Dr. SAVILE (London), referring to the exfoliative skin diseases mentioned by Dr. Pye-Smith, said that his subsequent experience of the epidemic skin disease led him to believe that renal disease formed a predisposition to contract the former. Out of five or six cases of such complication which he had seen, all were fatal. He regarded it as a very serious sign.

Dr. BRADBURY (Cambridge) had seen several cases of skin diseases occurring towards the end of morbus Brightii. He had observed erythema, and one case was markedly urticarial. In cases of interstitial nephritis he thought the element gout, plus poisonous matter retained in the blood through imperfect elimination by the kidneys, might be a factor. He admitted this did not explain all cases, especially those of chronic tubal nephritis. He was of opinion that the prognosis in these cases was unfavourable—that the end was not far distant.

Dr. WALDO (Clifton) asked Dr. Pye-Smith whether he had often noticed that the serum after blistering cases of chronic Bright's disease was hæmorrhagic.

Dr. GRANGE had noticed urticaria.

In his reply, Dr. PYE-SMITH did not think there was any evidence of uræmic origin; he had never seen skin affections in very bad cases of Bright's disease. Eruptions did not give him that grave augury as to prognosis which had been mentioned by other speakers. He had never noticed urticaria as seen by Dr. Grange. He was extremely sceptical as to the influence of gout. In reply to Dr. Waldo, he had had no experience of blistering leading to hæmorrhagic serum; in this respect he would point out that in Bright's disease one should never give opium or mercury, or apply a blister.

ON THE GUINEA-WORM.

By PATRICK MANSON, M.D. ABERD., F.R.C.P. LOND., ETC.,
Physician to the Seamen's Hospital, Greenwich.

WHEN mature this singular integumental parasite—*dracunculus medinensis* or guinea-worm, of which the female form alone is known, attains an enormous length—2, 3, or 4 feet. Though long, she is very slender, having a diameter of about the tenth of an inch. Her anatomy is very simple; practically she may be described as a musculo-cutaneous tube, enclosing an exceedingly delicate uterus, which, packed with millions of coiled up, long-tailed embryos, extends from mouth to tail. The head of the adult worm is rounded off, and is provided with a punctiform mouth and a crown of minute papillæ; the tail end is furnished with a sort of hook which possibly functions as a holdfast. The alimentary canal is a minute tube compressed and thrust to one side by the uterus. Vagina and anus are wanting—at all events they have not been seen; probably they are obliterated by the pressure of the enormous uterus.

When the embryos in her uterus attain a certain degree of maturity, the worm travels slowly through the connective tissues of her host, proceeding almost invariably in a downward direction towards the lower extremities. She generally gets as far as the ankle or foot. Arrived there she drills a minute hole in the derma, the superjacent epidermis being raised up as a bleb. In a day or two the bleb bursts or is broken, disclosing a superficial ulcer with the little hole, leading to, or, more rarely, occupied by, the head of the parasite, at its centre.

The prevailing idea is that the worm now creeps out, or is pulled out, and that her body, being cast away, decomposes, and so liberates the embryos. Another idea is that the worm breaking down in the tissues, her young escapes in the purulent discharge which the irritation of her presence excites. It

can easily be shown, however, that neither of these views is correct. The worm gives rise to no purulent discharge so long as she is alive; nor, left alone, does she quit the body until she has first got rid of her young. This can be shown by the following experiment:

Squeeze a little cold water from a sponge so that the stream shall fall on the sound skin within an inch or two of a guinea-worm ulcer; at the same time watch the little hole alluded to at the centre of the ulcer. In a few seconds a droplet of a whitish fluid will be seen to well up in the little hole, or a delicate tube will be protruded from it for an inch or more, and then suddenly rupture. Collect a little of the fluid that has welled up from the hole or escaped from the ruptured tube, and place it under the microscope. It will be seen to contain hundreds of coiled-up, apparently dead, embryo guinea-worms. Instil a little water below the cover-glass and watch. In a few minutes the embryos seem to wake up, stretch themselves, move, and in a very short time they are swimming about vigorously. Manifestly they are in their proper element—water.

The explanation of these facts, which I have frequently witnessed and shown to others, is this. The parent guinea-worm instinctively makes her way to the foot or ankle because her young are most likely to get to water in that situation. In guinea-worm countries the natives wear neither shoes nor stockings, and their feet especially are frequently in puddles of water. In some strange way the guinea-worm recognises this fact, and also recognises when the foot of her host is actually in contact with the water. So she makes her way to the foot or ankle, and at the right moment, when the foot touches water, expels her young just as when we experimentally douche the limb she is lying in. I find she takes about a fortnight to empty her uterus in such intermittent efforts at parturition. When all her young have been expelled she begins to come out herself, and can then be more or less readily withdrawn, or she may break down and excite suppuration. I may mention that as the parasite has no vagina she gets rid of her young through her mouth; the contractions of the musculo-cutaneous wall, in response to the stimulus of water applied to the skin of her host, cause the uterus to prolapse through the mouth and burst. An inch or two of uterus prolapses each time the stimulus is applied; becoming very tense under the sustained contractions of the body of the worm, it ruptures and shrivels up and so on until the entire organ is in time expelled.

The object of all these curious arrangements is to give the guinea-worm embryo the best possible chance to get at its intermediate host—a fresh water crustacean, cyclops quadricornis. Fedtschenko, now a good many years ago, discovered that cyclops was the intermediate host of the *dracunculus*, and convinced Leuckart and other helminthologists of this. But, so far as I know, his experiments had not been confirmed or repeated until last year. Having a case of guinea-worm under my care at the Seamen's Hospital, I bethought me of testing Fedtschenko's statements, and also of seeing if the guinea-worm could be raised in England. I procured a large supply of embryos by the douching process I have described, and placed them in watch glasses and little bottles, together with a number of cyclops collected from ponds in the neighbourhood of London. They were placed together one evening. On the following morning, on looking at my cyclops with the microscope, I found that nearly every one of them had some ten or twenty guinea-worm embryos coiled up and wriggling about in their body cavities. The parasite had penetrated the armour of the cyclops by attacking it between the joints of the ventral plates; it does not get to the body cavity through the alimentary canal after being swallowed. I kept the cyclops alive for many weeks, and watched the slow metamorphosis of the incarcerated embryos. I repeated the experiment with the same success this year, as the preparations (for most of which I am indebted to Mr. Rousselet) and Mr. Andrew Pringle's very telling photographs show.

In this last set of experiments the parasites and the crustaceans were placed together on May 10th. I dissected, or rather crushed, a few cyclops from time to time, and so could follow the metamorphosis step by step. I found that soon after it enters cyclops the young guinea-worm changes its shape. When a free swimming animal the little embryos body is flattened from side to side, something like a very

¹ Read in the Section of Dermatology at the Annual Meeting of the British Medical Association held in London, July-August, 1895.

much elongated flounder. Soon after its entry into cyclops this flattened body becomes cylindrical. The embryo then, after a very variable time, casts its transversely-striated skin, and, along with this skin, gets rid of its long slender swimming tail, a short, conically-shaped, pointed tail, sometimes a more rounded stump, taking its place. Apparently Fedchenko overlooked the cylindrical condition of the embryo and the formation of this conical tail. Later the parasite moults at least once again, the short conical tail giving place to a sort of tripartite caudal arrangement, something like a minute three-toothed trephine. Simultaneously with the changes described the young worm increases in size, its alimentary canal undergoing considerable development and becoming filled posteriorly with a brown granular material.

It is to be presumed that when this metamorphosis is completed the parasite is ready for transference to a human host by being swallowed in drinking water and while still in cyclops, and that under favourable circumstances it would attain maturity after boring its way into the connective tissues of its new human host.

I saw the metamorphosed guinea-worms alive and moving about in cyclops on July 19th, that is seventy days after their introduction. Fedchenko found that in the warmer climate of Turkestan thirty-five days sufficed for the metamorphosis. It takes longer in England therefore.

These are interesting biological facts. At the same time, they have one or two obvious practical bearings on the prevention and treatment of guinea-worm disease. First they show how desirable it is to abstain from unfiltered or unboiled drinking water in guinea-worm countries. They also indicate that it is wrong to commence winding out a guinea-worm before she has expelled all her young, premature attempts at winding out being unphysiological, and sure, or nearly so, to end in rupture of the worm and the extravasation of myriads of young into the tissues, with consequent cellulitis and extensive sloughing. Though I unhesitatingly condemn premature attempts at winding out, I am inclined to think that the recently-recommended treatment of guinea-worm by local injections of weak perchloride of mercury solution, with the view of killing the worm and procuring her absorption under aseptic conditions, is worth a trial.

Dr. HARRISON (Clifton) asked Dr. Manson whether it were possible for a mass of guinea-worms to get encysted in the pleural cavity of a rhea, or American ostrich, as he had found a large cyst containing thirty or forty worms certainly closely resembling guinea worms in that animal about two years ago.

Dr. MANSON said, in reply, that in dogs and many other animals various forms of filaria and other worms had been met with in the pulmonary vessels. The guinea-worm was known to occur in very many of the lower animals—dogs, horses, etc.—but he was not certain whether it had been found in the lungs.

A DISCUSSION ON DIET IN THE ETIOLOGY AND TREATMENT OF DISEASES OF THE SKIN.¹

L.—W. ALLAN JAMIESON, M.D., F.R.C.P. Edin.,

Physician for Diseases of the Skin, Edinburgh Royal Infirmary, etc.

It appears to me that the object to be attained by discussions on particular and selected subjects at such a meeting as this is to elicit from those present facts which have come under their own observation bearing on the question to be considered. It is in this way, and in this way only, that the sum of our information can be by such means augmented. To pave the way to this end the member appointed to open the debate ought to lay down shortly the state of our knowledge on the matter at issue, and so to suggest to the minds of his audience lacunae which one or other may be in a position more or less completely to fill up. Looked at in this light the topic with which we have to deal at present is: Diet in the Etiology and Treatment of Diseases of the Skin. It thus divides itself quite naturally into two heads intimately related to each other.

¹In the Section of Dermatology at the Annual Meeting of the British Medical Association, held in London, July-August, 1906.

First, then, with respect to the influence of food, taking the word in its widest sense, in causing or maintaining cutaneous disorders. There are at the outset certain limitations which narrow our field of observation. One of these is the relative frequency with which the ailment occurs. It is evident that in the case of uncommon complaints their very rarity acts as a barrier to exact inquiry. It is not possible to collect a sufficient number of instances to enable us to arrive at any definite conclusions on a matter which is in itself one of great difficulty. Again, many parasitic diseases are so far local disorders that the effect of diet in modifying the soil may be inconsiderable. There are diseases, too, of a chronic nature, such as scleroderma or fibroma, with respect to which we possess so far no available information; or acute maladies, as herpes zoster or erythema iris, in which there is hardly any opportunity afforded for due estimation. There remain, however, after eliminating those not yet accessible, some with regard to which it may be possible to reach something positive. Such are, of the affections met with in this country eczema, assuming this to mean broadly a catarrhal process, hyperidrosis, acne, dermatitis herpetiformis, lichen, lupus, epithelioma, and sarcoma. Unfortunately the data at disposal, even bearing on these diseases, are meagre, and to a considerable extent unreliable. We must reject in large measure the statements volunteered by our patients, though we thereby get much information. The former are vitiated by preconceived impressions, or are based on ill-founded deductions; the latter are necessarily imperfect. The patient in nearly all cases ascribes an immediate effect to his diet, though it may be obvious on the least reflection that the action, if exerted at all, must be remote. It is very perplexing, too, to allot the proper share to the individual constituents of a mixed dietary, in which there is no one largely preponderating and constant element, or any essential component markedly defective. The environment, too, of the individual has a relation to digestion which is in many instances beyond the power of our appraisal. The habits of the man as to regularity of ingestion or the reverse, come extensively into play in promoting or interfering with nutrition, and these may be unknown to or concealed from us.

Some articles of food act in producing cutaneous disorders in an immediate manner by the exertion of what may be termed a toxic or dynamic influence. Of this result urticaria is perhaps the best example, but here idiosyncrasy comes into operation, since no one ingredient is capable of evoking wheals in all persons, or at all times even in the same person. Once initiated, however, the morbid tendency is apt to persist long after the original exciting cause must have ceased to be efficient. In such cases some ferment may cling to the intestinal walls, and continue for an indefinite period to exert its action on the products of digestion as they descend. This forms a link in the chain connecting this class with the next, in which the instrumentality of diet is a remote one. Much more frequently the influence of diet in provoking skin disease is to be attributed to slow and long-continued mal-assimilation. It is thus rather predisposing, the determining cause coming from without or depending on some accidental circumstance. An appropriate illustration of this is afforded by pellagra, in which, while diseased maize is the agent which morbidly disturbs the system, it is the sun's rays which light up the erythema, the integumentary manifestation. Viewed in this way it is not so improbable that some as yet undiscovered dietetic error may sow the seed which eventually under the solar beams ripens into xeroderma pigmentosum or hydroa vacciniforme.

When we endeavour to accuse special articles of food or drink of possessing this remote power of occasioning cutaneous disturbance, there are but few to which we can positively bring home the charge. Alcohol abused tends to produce a degree of over-ready penetrability of the tissues, shown on the one hand, so far as the integumentary system is concerned, by the clammy moist hand of the habitual toper; but it can also, on the other, occasion undue and permanent dilatation of the blood vessels of the face and give rise to rosacea and a coarse greasy skin. Since this does not supervene in the case of all who are prone to this form of indulgence we must in many instances invoke some exciting factor. Of these exposure to all weathers is certainly one, but confinement in

close, ill-ventilated rooms and continued stooping are others. Ten, when similarly partaken of too freely, too strong or too hot, may, as Mr. Hutchinson has observed, give rise to cold hands and feet, combined probably with some chronic sub-acute gastro-intestinal catarrh. It does induce, mostly when associated with an otherwise insufficiently nutritious dietary, a shrinkage and withering of the exposed portions of the integument, with a loss of its natural transparency at too early an epoch in life. I am unable from my own observation to confirm Dr. White's statement² "that at certain seasons acute eczema is produced in some persons by eating fruit containing abundant acid." He has noticed this during the strawberry season, and again later at the period when pears and grapes ripen. The difference in climate between that of Scotland and Boston may account in part for this discrepancy; wild strawberries, too, have a more toxic effect than the cultivated variety; and, besides, fruit of any kind, gooseberries, perhaps, excepted, is never partaken of with us to the extent it is in the United States.

The persistent omission of fresh green vegetables, of salads, or of ripe fruits in their season from the dietary leads to a weakening and loosening of the tissues, with alteration of the blood vessels and of the constitution of the blood itself, followed by the occurrence of hemorrhages into the skin, and an etiolated condition of the integument which in its highest development we call scurvy. This may, however, manifest itself as milder types, as some forms of purpura in children or infants. In the latter the milk of the mother is probably, owing to her faulty habits as to diet, deficient in such salts, the absence of which is held to be the ultimate cause of some forms of extravasation into the skin. It is singular how long the system may hold out against such inadequacy in due materials. A man, aged 47, had for three years lived on a diet from which milk, green vegetables, and fruit had been entirely excluded, yet it was not until two months before his admission into my wards on May 1st, 1895, that he had begun to experience the first symptoms of scurvy.

Though in January and February the cold had been unprecedented, and this may have acted as a determining cause of the outbreak in his case, he was unwilling to accept such an explanation, and indeed we failed to account positively for the onset. Once started the symptoms became pretty rapidly ingravescent. Not a few cases of eczema of the legs are intensified, probably some are directly due to this scorbutic diathesis. Given a small abrasion on the skin, or merely a varicose condition of the limb, the blood stasis consequent on these is apt to be further complicated by hemorrhage into the integument, often masked by the inflammation, and interrogation elicits the fact that the diet for a long period of time has been one into the composition of which green vegetables seldom or never enter. If the individual lives in the country, or is much out of doors, the exposed parts of the body, as the face and hands, may indicate no suspicion of anemia, and the person himself may declare his health perfect. Dr. Burney Yeo³ holds that eczema is prone to appear amongst boys at school who are kept on a too exclusively meat diet, without having a corresponding proportion of fresh green vegetables. The taste for these is apt to be lacking, possibly fostered by the unattractive manner in which they are served. Since my attention has been directed to this point, it has surprised me in how many instances of eczema, not of the classic seborrhoeic type, the diet has proved on inquiry to be defective in this particular.

While eczema occurs in the ruddy and robust in appearance, as well as in the anemic and ill-nourished, we can often discover a contributory cause in some dietetic error. The observation of Tilbury Fox⁴ that eczematous subjects are, as a rule thin, pale, and with evidence of malnutrition, with irritable and dry skins, and little, often no, subcutaneous fat, is borne out by subsequent research. In the case of children particularly, but also in adults, the source of the fat with which in the main their tissues is impregnated, is of importance. That elaborated from sugar and starches is much less permanent than that derived from such ingredients as oatmeal—a cereal rich in natural fat—from milk of good quality, from butter, or from the assimilation of that in the flesh of

animals which have been reared on hay or grass. The softer fat disappears more readily under the exigencies of their existence, in human beings, and renders those only, or mainly so fortified, more prone to eczema, especially if of strumous habit. In some fat is a "constitutional tissue," in others it is merely a reserve, a provision to be consumed at the first demands of the system. Still further, as bearing on eczema specially, very thin persons bear cold badly.⁵ Yet it must be confessed that even after careful cross-examination, it will be found difficult, in many cases, to fix on any one alimentary substance which can be exclusively blamed as predisposing to eczema.

Too limited an amount of water imbibed to enable the kidneys to carry out their function satisfactorily promotes the gouty tendency which underlies some forms of eczema, notably the dry variety affecting the palms. In these cases enough fluid possibly is taken with meals, but not a sufficiency in the interval, when, the stomach being empty, it can be rapidly absorbed, dilute the blood, and flush the renal tubules. In numerous cases the meals are too much crowded together, and so an early dinner encroaches on an incompletely digested breakfast, or an ample tea follows too closely on a fairly substantial midday repast. In other instances, too long a space has been allowed to intervene, no, or but very scanty, nutriment having been partaken of between an early breakfast and a late dinner, in the case, too, of persons who use their brains more than their muscles. Indeed, in a large number of cases of eczema occurring among the middle classes of society, the fault has appeared to me to lie more in the defective arrangement as to time than in the composition of the meals themselves. In infancy, childhood, and during school life, however, unsuitability of food rather than insufficiency in amount tends to induce eczema. Hurry in taking breakfast, to avoid being late, tells very injuriously in the case of children who attend day schools.

All these latter factors, irregularity and haste in particular, bear a part in the production of alopecia areata, a disease which is becoming alarmingly prevalent. The neurotic theory of its causation seems to me the most plausible, as it is the one best supported by clinical evidence. Dietetic errors which lower the vitality of the system of trophic nerves, are at least among the influences which favour the occurrence of this morbid atrophy of the hair.

While we cannot impugn any special article of diet as being the cause of psoriasis, yet alcohol intemperately used by those affected with it intensifies and aggravates its symptoms. The disease in such circumstances invades extensive areas with very great rapidity. The scales become dark-coloured and thick, the integument becomes involved in all its layers, and proneness to degenerate into exfoliative dermatitis is exhibited.

Dermatitis herpetiformis is possibly dominated, if not actually induced, by diet. We may infer this from the fact that in those liable to it the symptoms are always aggravated by the administration of iodide of potassium, and attacks have even been occasioned in individuals not previously affected by the exhibition of that drug. Further, in an instance reported to me by Dr. Muirhead, the outbreaks were slight or did not occur when the patient was fed on vegetable food and meat withheld; so soon as flesh was given the eruption appeared, to cease again on its withdrawal. As has been suggested as to urticaria, some toxic fermentation may be, if not an originating at least a maintaining cause.

The subject of diet in the causation of lichen planus has not been investigated, but many of those who suffer from it verge on the condition termed neurasthenia. They have been worried, overworked, or are more or less liable to indigestion or neuralgia. Though food may not be directly blamable, yet there is often distinct evidence of malnutrition, in the shape of some degree of wasting with constipation, and the feeding may be to a considerable extent at fault. It is true at the same time that cases also occur in fat women over 40 or 45, but obesity to some degree is at that age physiological, and partly irrespective of diet.

Boils are undoubtedly due indirectly to diet, though a local irritation may serve to determine the locality affected.

⁴ *Lancet*, *Physiology of Bodily Exercise*, 1886, p. 195.

⁵ *Lauder Brunton, Disorders of Digestion*, 1889, p. 130.

In numerous cases we can trace the effect of food, as is seen in the sudden alteration from a full and mixed dietary to a restricted and defined one in the process of training; or from a simple, perhaps a monotonous and possibly ill-chosen one, to a richer, more substantial and varied, as in domestic servants coming from home—in the country it may be, or from a crowded street in town—to a first "place."

Acne in girls, and to some extent in youths also, is very often the result of injudicious dietary. There is a belief prevalent among women—from which the proprietors of boarding-schools are far from being exempt—that girls do not require to be well fed, do not need as ample a supply of nutriment as do boys. Hence at home girls are too often allowed, if not even encouraged, to eat sparingly, while at many of these establishments, both in this country and more so abroad, the food is apt to be insufficient, unsuitable, or unattractive. This occurs, too, at a time when development is exceedingly rapid, when to the mental work frequently unwisely imposed there is the added strain of the advent of puberty; hence, not only is the system in general disturbed and anemia produced, but complementary nutrition is disordered at the same time, and comedones, acne, and seborrhea appear.

In lupus, as in other forms of tuberculous disease, the habitual elimination of fat from the dietary or the too limited employment of oily materials in the food of the young has a powerful predisposing or maintaining effect. Those affected with extensive lupus not infrequently admit a distaste to fat.

Allowing for greater skill and care in diagnosis, there can be little question that a marked increase in the prevalence of some forms of cancerous disease has taken place during the last half-century. "Epithelioma," observes Mr. Christopher Heath, "I am quite prepared to say, has increased very largely during the last twenty years." And it is with epithelioma that we have chiefly to do. As to sarcoma less can be said with certainty. Although in the past fifty years there has been a vast improvement in comfort, while there has been an augmented expenditure of vital energy, a lengthening of the average of life with a larger amount of waste, both of which may have an influence, there are two notable alterations in dietary which have occurred within this same period. One is the growth in the consumption of butcher's meat, the other the remarkable rise in the employment of tea at all ages and in all classes as a beverage. "It has been suggested," says Dr. Burney Yeo, "that, amongst other evils attending an animal dietary, one is that it favours the tendency, where it exists, to the development of cancer." Cancerous affections are, however, prevalent among persons who have never had the opportunity of indulging freely in animal food. It is far otherwise with respect to tea, and I hold strongly the opinion that the abuse of tea, or indeed its use at all during the period of growth, has much to do with the increase of cancer.

The second part of the subject under discussion—Diet in the Treatment of Diseases of the Skin—though one on which a good deal might be said, for it is, in a measure, in our own control, need not very long delay me, since it follows in the main as a corollary from the facts elicited as to causation. The truth is, the dietary necessary in cutaneous diseases is that which is called for by the exigencies of the case immediately under our care, personal idiosyncrasy being always allowed for when ascertained to exist. It is abundantly clear from what has preceded that neither green vegetables nor fruits in their season should be wholly excluded; that animal food should be moderate in amount, and duly selected as to digestibility; and that hydrocarbons in as fine a state of subdivision as possible, and in fresh condition, must form a part. There are some particulars, however, relating to the mode in which these kinds of food ought to be taken which need mention. Thus, vegetable broth is an objectionable way of giving green food. The pieces contained in it are too often hard from insufficient boiling, and, being at the same time small, are swallowed whole, and so escape proper mastication. Potatoes, also, unless carefully boiled in their jackets so as to be perfectly mealy in consistence, roasted, or mashed, are not advisable. Only when thoroughly boiled porridge is proved to disagree should it be eliminated from the category of break-

fast dishes. It is essential that the diet should contain not merely nutritious, but also waste, material. The tendency at the present day is to concentrate nutriment, to ply the system with the most easily assimilable substances offered in the form which is held at the same time to be the most digestible. But to enable the absorbing vessels to exercise selection, this must be diluted with a sufficiency of redundant or waste material, which by its bulk opposes resistance to the muscular contraction of the stomach and intestines, thus maintaining their peristaltic efficiency, and obviating constipation. In the diet of adolescents suffering from skin diseases who are at all anemic, special care is to be exercised that the supply of animal food is ample, for this "contains the maximum of iron, and the material necessary for red corpuscle making." An important point is to avoid too many mixtures at any one meal. Our efforts must be directed to correct whatever has been found to be defective or erroneous in quantity, quality, or time of taking meals. While alcohol should be avoided in rosacea or acute eczema, the mainm which guides us in general as to its advisability or otherwise holds good in cutaneous diseases. "If the meal is relished as much, and digested as completely, without as with a moderate allowance of alcohol, it is superfluous."

In conclusion, one must bear in mind that however careful a scheme of diet may be constructed and laid down by the physician, and its expediency accepted by the patient, he is dependent on his wife or housekeeper, in the first place, on his cook in the second, for the regulations being strictly adhered to. As these persons have not the same direct interest in their due fulfilment as the sufferer himself, and very probably regard some of them as of the nature of fads, they are apt in the long run to be but inefficiently and perfunctorily carried out, even in cases where the circumstances are otherwise favourable. Hence all directions should be as plain and simple as possible.

II.—WALTER G. SMITH, M.D.,

President of the Royal College of Physicians of Ireland; Physician to Sir Patrick Dun's Hospital.

DR. ALLAN JAMIESON in his careful paper has dealt fully with the kinds of food which appear to have a tendency to induce individual skin diseases, and with the forms of cutaneous disease which may be considered to be influenced or caused by particular dietary or by special elements in our food, and he has given us useful hints upon treatment.

The few remarks which I shall offer to you may be taken as complementary to his. I propose to dwell rather upon the limitations of our knowledge and the imperfection of our data, in the hope that clearer views may emerge from our discussion.

Let me, in the first instance, ask. Have we any certain or exact scientific knowledge of the influence of diet in the causation of diseases of the skin? The belief in the potency of this influence is universal with the laity, and widely acknowledged by the profession generally. But the practice of physicians is partly traditional and is, unfortunately, not always based upon real conviction or sound knowledge, and many circumstances conspire to tempt them to give formal advice which rests upon a slender foundation. The present opportunity seems a suitable time to re-examine the groundwork of our belief, and it may fairly be expected that the discussion to follow will result in a better definition of our position as medical advisers upon dietetics towards our clients—the public.

I start with the two propositions that the real influence of diet in the causation of skin diseases is a small one, much less than it is credited with, and that our substantial knowledge of the subject is very limited. Fundamentally the action of food and of drugs is to be explained upon similar general principles. But great as are the difficulties of forming a correct judgment of the mode of action of a drug, still greater are the complexities which surround questions of dietetics in the causation of cutaneous affections. We are always and in all places confronted with the problem of the idiosyncrasy of the individual, which is a real and perplexing difficulty, and should make us more cautious in formulating cut and dry rules for the guidance of our patients' stomachs.

In very many cases an intelligent and temperate patient

¹ International Clinica, vol. xv, Lincea series, 1890, p. 138.

² Burney Yeo, op. cit., p. 301.

knows, or ought to know, better than his doctor what suits him and what aggravates his complaint; and I heartily endorse Sir W. Roberts's simple and sensible rule of conduct, namely: "It may be regarded as certain that any food or foods necessary, the use of which is followed by a sense of discomfort, is not beneficial to that individual."¹⁰ And conversely, as Pye-Smith puts it: "What most people eat is for most people wholesome, and what a natural appetite finds appetising seldom disagrees."¹¹

The tendency of modern inquiries has been largely towards the more exact determination of etiological factors. Hence we have been gradually led to minimise, laying stress upon vague and indefinite conceptions, such as diathesis and the like, and of these vague causes diet is, I think, one so far as the skin is concerned. Moreover, the rise and progress of bacteriology has profoundly modified our notions of the cause of many diseases of the skin and influenced our treatment. I need only allude to the pathology of boils, carbuncles, and acute suppuration generally.

Although it is by no means proven that eczema, and even less psoriasis, are parasitic diseases, still the more ventilation of such a possible cause for these affections tends to throw into the background loose speculations and traditional surmises as to the effect of dietetic causes in originating diseases of the skin.

We may picture to ourselves four modes or ways at least in which diet may possibly influence the skin:

1. Through the general nutrition of the body. Nutrition is influenced in a very subtle manner by the quality of the food (Roberts), and insufficient or improper food lowers the tone of all the tissues, skin included. Under such conditions we meet with scorbutic and purpuric affections. Destructive and pyogenic microbes find a more suitable soil whereon to fester, and hence a greater liability to pustular and gangrenous developments. The fungus of "thrush" lies in wait for debilitated constitutions, and favus is more common among the neglected and ill-fed poor.

2. By acting as a reflex stimulus from the gastro-intestinal tract. This is doubtless the most common mode. The physiological relationship between the skin and the digestive mucous membrane is incontestable, and proofs are abundant. Over-eating, on the one hand, and on the other the use of unsuitable, indigestible, or irritating articles of diet are frequently followed by either neurotic or vasomotor disturbance in the skin—for example, urticaria. The skin affections producible in this way are all transitory, and disappear spontaneously, as a rule, when the causes cease to act. Many people eat far too much, and overload their digestive capacity. And some of them would pay a worse penalty than they do were it not for the dinner pill, the morning saline, or the occasional visit to Carlbad. Three practical considerations flow from these thoughts, namely: (a) The utility of purgatives in such cases; (b) the importance of good cooking in avoiding or overcoming dietetic irritation; (c) the due regulation of the diet as to quality and kind.

3. By absorption into the blood of irritating substances or of products of chemical change, which indirectly affect the skin. In this direction we may look for explanation, in part at least, of the occasional injurious effects of tinned and preserved foods. Pathogenic bacteria may undoubtedly enter the body with articles of diet. We are all familiar by daily observation with the hyperemia of the skin which ensues upon full doses of alcohol.

4. The skin may suffer in virtue of being one of the channels or avenues of elimination. Certain drug eruptions arising from volatile oils or oleo-resins—for example, copaiba, eucoba, and turpentine—are perhaps explicable upon this hypothesis. And upon similar grounds we caution our patients against the use of highly seasoned foods and spices (that is, volatile oils) in erythematous and acute inflammatory affections of the skin.

To turn now to another aspect of the question, namely, diseases of the skin in relation to diet. We can at once make three groups: (1) Cutaneous diseases liable to originate in, or acknowledged by common consent to be materially influenced by, diet. (2) Cutaneous diseases possibly, but not proven to be, influenced by diet. (3) Cutaneous diseases cer-

tainly not affected by diet, for example, herpes, pemphigus, lichen ruber, ichthyosis, ringworm, etc.

In Class 1 we may instance: (a) Erythema—certain forms of; (b) urticaria; (c) pruritus; (d) acne rosacea; (e) acne vulgaris—perhaps. Bulkley states that in some persons crops of acne follow the free use of buckwheat;¹² and Pye-Smith affirms that in some patients a fresh outbreak of follicular inflammation can be produced at will by eating "crystallised" fruits, strawberry jam, or orange marmalade.¹³

In Class 2 may be placed psoriasis, most cases of eczema, and of acne vulgaris. Eczema in children is very frequently attributed to dietetic influences, such as too free use of sugar or even of milk. But, for my part, I quite concur with Dr. Cheadle in never having been able to satisfy myself that eczema is a diet disease.¹⁴ Many infants attacked with severe eczema are of a ruddy colour, have a good appetite, and with all the appearance of excellent health.

It is the present habit to ascribe many skin diseases to gout, and we hear every day of "gouty eczema," "gouty psoriasis," and the like, and various queer nondescript ailments are shunted off the main line to a gout siding. Patients ask for and expect to get from us minute directions about their culinary arrangements, yet few English practitioners conversant with diseases of the skin would go so far as Brocq in saying that the regulation of the diet is the most efficacious internal treatment for eczematous patients. The hypothesis of leprosy having been transmitted by food of any kind, in particular by fish, has not been established by further examination. Boils are often ascribed to errors or deficiencies in diet. With our present knowledge of the pathology of boils, it is to my mind incredible how a crop of boils, as is stated on good authority, can arise through mere change of diet, for example, a surplus of animal food. In England the consumption of meat is 135 lbs. per head per annum, in France it is only 46 lbs. per head per annum. Are boils so much more common in England? Eczema affects the sexes almost equally, although men probably eat two thirds of the total meat and drink probably three-fourths of the total alcohol consumed in the United Kingdom.

If we direct our thoughts to determine what special articles in our dietary may be held responsible for harming the skin we have not a long list, as will be gathered from the preceding remarks. Coffee, tea, perhaps; highly spiced foods, excessive use of hard salted meat, shellfish, abuse of alcohol, and foods, such as starch and other carbohydrates, which may lead to production of excess of acids (acetic, lactic, butyric) in the intestines. A widespread and deeply-rooted custom is the strict prohibition of salted food in diseases of the skin. For many years I have ignored this dictum, and neither my patients nor myself have had reason to regret the liberty accorded to them. Chloride of sodium is a very harmless salt, and some people with weakly digestion or a jaded appetite will relish and easily digest a thin slice of ham when the stomach would revolt against other meat.

Does alcohol in moderation cause any skin affection? That it is apt to aggravate itching and increase an already existing congestion of the skin is quite true. Most of the Asiatic populations, with the exception of the Japanese and the Indian Paraces, drink no alcohol. Yet I do not know that this experiment, on the large scale, indicates any advantage to those races *quoad* the skin.

I cannot but believe that the ill-effects of alcohol, and I may add of tobacco, are exaggerated by their extreme opponents, at any rate, as regards the skin. Plenck, quoted by Bulkley, remarks of acne: "Plures curavi suadendo ut vinum bibere inciperent."

Lastly, a word as to the practical outcome of all this. How are we to intelligently answer the questions so often addressed to every one of us by our clients? "What shall I eat? What shall I drink?" In cases such as diabetes, gastric ulcer, and enteric fever there is a tolerable degree of unanimity in our answers. But what about the slighter ailments and indispositions which constitute the bulk of our practice?

A large number of our patients with affections of the skin are not obviously out of health, and are well able for their

day's work in the world. Yet these persons are apt to ponder over their health, put us through a catechism as to their diet, almost constrain us to go beyond our knowledge, and even glory in the dietetic chains which are fastened around them by their medical advisers. Unluckily it sometimes happens that one practitioner's rules flatly contradict those of his neighbour, and so a shrewd patient is liable to arrive at the unpleasant conclusion that, as Sir W. Roberts puts it, our notions on dietetics are little better than a farrago of whims and fancies.

We are too formal in our rules, and impose unnecessary and unmeaning restrictions. We prescribe diet by printed forms, making no allowance for idiosyncrasies, and giving even our educated patients little or no latitude or opportunity for exercising their own sense of what is good and what is bad for them. In my judgment the main precept we need enjoin as a golden rule upon our patients suffering from diseases of the skin is moderation and temperance in all matters of eating and drinking, especially as regards alcohol. And we should seek to train the public to observe for themselves whether such and such an item of diet really agrees with them or not.

With all this borne in mind there is plenty of room for judicious advice tempered with common sense, and a hint or a suggestion is often better, although less showy, than the imposition of conventional rules. This latter course is, no doubt, sometimes requisite with the hypochondriac, the neurotic, or the careless, who will not listen to, or are incapable of understanding, the still small voice of healthy instincts and of personal experience.

To sum up in a few words:

1. Very few skin diseases are directly traceable to dietetic causes, but improper diet may aggravate existing eruptions. Idiosyncrasy must be largely allowed for.
2. The diseases that may so arise are of a transitory character, and mostly belong to the class of erythemata.
3. Diet has very little influence in promoting the cure of cutaneous eruptions. The results are far behind popular expectations, even in such cases as acne rosacea, where we are led to hope for much.
4. Avoidance of alcohol, regulation of the bowels, and the cure of anaemia are of infinitely greater importance than special dieting in the management of diseases of the skin.

Dr. RADCLIFFE CROCKER, the President of the Section, agreed most fully with Dr. Smith's views, but he admitted that in practice it was not wise to go in the face of the prejudices of patients in the matter of diet. Salt in moderation had no effect, either in producing or modifying skin diseases. He considered, however, that undigested starch and sugar were apt to disagree in and aggravate cases of urticaria and eczema. As regards alcohol, he thought there was much difference in the exact form of alcohol taken, the fully fermented forms being the least harmful. In the treatment of furuncles careful local antiseptic measures were far more useful than directions as to diet. Dr. Crocker concluded his remarks by insisting on the importance of the cook.

Dr. A. J. HARRISON (Bristol) considered that fruit disagreed with children more frequently than anything else. He did not think that food had anything to do with boils. In his opinion there were patients wholly unable to take certain alcoholic preparations, and he instanced champagne as capable of always disagreeing with the same individual.

Dr. A. S. MYRTLE (Harrogate) agreed with Dr. Smith. He had ceased to impose strict dietary rules in cases of chronic skin disease, and he was convinced that a patient's own taste in food might as a rule be safely followed. Dr. Myrtle had been greatly struck by the good effects of a change of diet on leprosy in Norway. He considered that well-matured spirit was wholesome in moderation. He thought he had traced gout to excessive tea drinking in some cases.

Dr. GEORGE THOM thought the frequent recommendation of whisky by medical men was becoming a great evil. He doubted the alleged prejudicial effects of tea drinking on the skin, since they were not obvious in those countries where tea drinking was very much more prevalent than in England, such as China and Japan. Nor was the method of preparing the beverage of so much importance as was thought. Strict

diet rules, in his own experience, had been productive of much discomfort and sometimes injury in the case of patients suffering from skin disease. With regard to alopecia areata, he had usually found the condition in strong young adults; it was more probably due to contagion.

Dr. MORGAN DOCKHILL insisted on the absurdity of the dictum that diet had scarcely any effect on most forms of cutaneous disease. He did not agree with Dr. Smith's views. He considered that diet was an important factor in eczema, acne, etc., and also in tuberculosis of the skin. Lupus was rare among the Jews, owing to the care taken to exclude tuberculous meat, which was probably sold to poor Christians. He was in the habit of excluding meat from the diet of lupus patients. He considered alopecia areata was related to diet.

Professor McCALL ANDERSON (Glasgow) agreed with what his friend Dr. Jamieson had stated. He held that it was not wise to take the patient's taste as a guide to diet. In Scotland there was a great abuse of tea drinking, which acted very injuriously. China tea was much more wholesome than Indian or Ceylon tea. He alluded to the importance of the teeth. Their proper care was as important as regulating the diet.

Dr. T. D. SAVILL agreed with the last speaker with regard to tea. He wished to emphasise the importance of alcohol in the etiology and treatment of skin diseases. He alluded to Anstie's interesting experiments on the vasomotor effects of alcohol. In his experience the omission of this article from the dietary had frequently cured skin diseases, even of very long duration.

Dr. BUCHANAN said that in cases of prurigo, pruritus, eczema, etc., in which itching was the prominent symptom, he had found that an exclusively vegetable diet for four or six months greatly alleviated the sufferings of the patients and materially aided in their recovery.

Dr. G. G. STOPFORD TAYLOR (Liverpool) was astonished at the extraordinary difference of opinion that existed. Lupus patients should always receive a most generous diet, as the vast majority of cases came from the poor and half-starved ranks of life. The diet of eczema should be conducted on common-sense principles. Alcohol should be avoided.

Dr. ALLAN JAMIESON, in reply, said he thought that boils were undoubtedly sometimes caused by sudden changes of diet, but it was merely in the inception of such that the diet had an influence; their further extension was due to auto-infection. The bad effects of tea on the skin were partly due to its substitution for nutritious food. As regards alopecia areata he thought, whatever might be its exact pathology, that bad feeding, including hurry in taking meals, was of considerable importance in its production.

Dr. WALTER SMITH also made a few remarks, and the discussion closed.

MEMORANDA:

MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, ETC.

SEVERE CASE OF CHICKEN-POX.

On June 22nd a child, M. H., aged 4, was admitted into hospital, the notification being scarlatina. The child presented a well-marked eruption, sore throat, temperature 102°. The rash gradually disappeared. On the fifth day after admission (June 27th) there was a sudden rise of temperature to 105°, followed by a most copious varicella rash all over body, head, scalp, palms of hands, and soles of feet. So close were the vesicles together that a pin point could not be placed anywhere between them. The only part free from eruption was the four large vaccination marks on the left arm. The case presented many appearances of variola, but each cell was unilocular, and collapsed entirely on puncturing. Some of the cells had the central depression or umbilication, although many of them were broad and flattened, and had a red areola. The contents of the vesicles, at first clear, became turbid, and on the fifth day (July 2nd) dried up into brown scabs and fell off. Vesicles appeared also on the inside of the

mouth and soft palate. After the spots fell off, especially on the nose and face, many pits were left.

This case was unlike chicken-pox in this respect—the rash came out all at once and not in crops; the shape of the vesicles, and the pitting after falling off of the scabs. The proof that it was not small-pox was the age of the child (4 years), the efficiency of the vaccination (four large marks), and the absence from the district of other cases of small-pox. Another peculiarity of the case was the evidence that the chicken-pox virus must have been in the child's system prior to the scarlatina, the symptoms of the latter disease being so well developed when the child was admitted; and the hospital had had no case of varicella previous to the admission of this child. The child was isolated at once on the appearance of the varicella rash, yet every other inmate of the ward has since had an attack of genuine varicella.

The case was seen by several leading medical men of the district, and the diagnosis of chicken-pox agreed upon by all.

O. H. PHILLIPS, M.D.,

Medical Superintendent of Infectious Hospital, Bucknal.

A CASE OF SPINA BIFIDA OCCURRING IN THE CERVICAL REGION.

THE unusual occurrence of spina bifida in the cervical region may be of interest to some of your readers, and so form an excuse for my encroaching on your valuable time and space.

On June 19th, 1895, I attended Mrs. B. in her first confinement, when she was delivered of a full-term female child, the labour being normal. At the birth of the child I noticed on the back of the neck a tumour which was about the size of a tangerine orange, slightly constricted at its base and depressed at its summit; the skin covering the tumour was normal, and plentifully covered with hair at the base, but became thinner as it spread over its surface, and at the apex was thin, glistening, and bluish-white in colour, and much wrinkled; the tumour could be emptied of its contents by pressure. The child died twelve hours after its birth. During its short period of life it had (the nurse informed me) several fits, the characteristics of which I am unable to describe, as I did not happen to be present at any of the attacks. I had the opportunity of making a post-mortem examination, and found the following conditions: The tumour communicated with the interior of the skull by passing through the foramen magnum and an opening in the neural arch of the atlas. The foramen magnum did not appear to be unusually dilated, the neural arches and formation of all the other cervical vertebrae being normal, neither was there any abnormality of the occipital bone, the torcular Herophili and the sinuses being complete. Spina bifida of the lumbo-sacral region is fairly common, but becomes rarer the higher the situation. In the Museum of the Royal College of Surgeons, amongst the specimens of the malformations, there is a specimen of a ligatured spina bifida occurring at the sixth and seventh cervical vertebrae, but I can find no record of a case occurring above this position, except accompanied by hydrocephalus or considerable malformation of the skull. In this case there was no other abnormality in the skull or elsewhere.

REPORTS

ON

MEDICAL & SURGICAL PRACTICE IN THE HOSPITALS AND ASYLUMS OF GREAT BRITAIN, IRELAND, AND THE COLONIES.

VICTORIA HOSPITAL FOR CHILDREN, CHELSEA.

AN UNUSUAL CASE OF ACUTE INTENTINAL OBSTRUCTION IN AN INFANT.

(By D'ARCY POWER, M.B., F.R.C.S. Eng., Surgeon to the Hospital.)

[From Notes furnished by Dr. CHANING PEARCE, House Surgeon.]

T. L. B., aged 8 months, a badly fed child, had been ailing for some time with bronchitis. He was comparatively well on April 6th, but his mother noticed that his mouth was

full of small white ulcers. He had a green motion on April 7th, about 7 o'clock in the morning. He began to vomit about 11 o'clock, and at 5.45 p.m. he passed a large motion of altered blood, containing small gelatinous masses. He was admitted into the hospital at 6.30 p.m. It was noticed at this time that he was drowsy, and occasionally drew up his legs and cried out as if in pain. His abdomen was soft, flaccid, and free from tenderness, whilst no tumour could be detected either by palpation through the abdominal walls or *per rectum*. At 11 p.m. there was much retching, and the belly was tender, especially upon the right side, where pressure caused increased retching. A cylindrical mass could be seen and felt in the right hypochondrium. It lay transversely, but did not pass beyond the middle line. There was a slight discharge of blood *per rectum*. I was summoned, and an hour and a-half later, or 13½ hours after the initial symptom, laparotomy was performed, inflation having proved useless. The intussusception was of the rare ileo-colic variety, in which the ileum slips through the ileo-cæcal valve and enters the colon unaccompanied by the cæcum, the apex of the intussusception being formed by the reflexion of the ileum upon itself. It could not be reduced *in situ*, the proper method, and the tumour had to be brought out of the wound. Reduction was then easy, and when it had been completed the thickened ileo-cæcal valve was distinctly felt. The wound was closed with deep sutures, and the child bore the operation well. It was fed from 5 a.m. with an ounce of peptonised milk every two hours. It passed a moderately good day after the operation. Its abdomen was flaccid, there was no vomiting, but its bowels were not open. The child had two motions on April 10th, the night but one after the operation. The first of these was of a reddish-brown colour, the second of a natural yellow colour. The food was well taken during this day, the child appeared to be comfortable, and the temperature fell to normal. It had two more motions during the day, both natural. At 8 p.m.—forty-five hours after the laparotomy—the child again began to vomit a brownish fluid. He refused his food, became drowsy, and was cold. He was in a condition of collapse by 11.30 p.m. His abdomen was then supple, but fuller than it had been during the day. The wound was perfectly aseptic. No tumour could be felt through the abdominal walls, but three lines of small intestine could be seen in the left hypochondrium. The child vomited all the following day, though it was not fed by the mouth. His bowels were open twice. The abdomen became more full, but it was not tender. There was retention of urine. The vomiting continued throughout April 12th, and there was one large and normal motion. The abdomen was still more full, but—as on the previous day—it was supple, and there was no tenderness. The coils of intestine were distinctly visible through the abdominal walls, though they were not moving so freely as on the previous day. Matters went from bad to worse, and at 4 p.m. on April 13th the abdominal wound was gaping widely, and the gut had become prolapsed. Dr. Pearce replaced it under an anæsthetic, and closed the wound with sutures. The child died on the following day.

The necropsy showed that the small intestines were distended with flatus to within 12 inches of the ileo-cæcal valve. The distension suddenly stopped at this point, although there was no visible cause for its arrest, either outside or within the intestine or abdomen. The colon, like the lower part of the ileum, was collapsed. The thickened ileo-cæcal valve projected for a short distance into the cæcum. The valve and the mucous membrane for about two inches beyond it were congested, but there was no intussusception and no signs of peritonitis.

Microscopical examination of a portion of the invaginated ileum showed a slight extravasation of blood into the whole circumference of the submucous coat. The glands, the adenoid tissue, the circular muscular coat and the serous coat appeared to be healthy in every respect. The individual fibres of the longitudinal muscular coat stained less deeply than they should do, and in many cases appeared to have undergone some degenerative change, for they were unduly granular and they were more highly refracting than usual. I hesitate to say that they had undergone fatty degeneration, as it is well known that similar changes are not unusual in the muscles of children. The extravasation of blood in the dilated part of the intestine immediately above the point of

constriction was slight but it was distinctly visible between the serous and the muscular coat. The layer of external longitudinal muscle presented changes similar to those described above as occurring in the invaginated portion of the gut. The other coats of the dilated intestine were normal.

REMARKS BY MR. D'ARCY POWER.—The case is an instructive one, for it shows that the symptoms of obstruction may reappear and even progress to a fatal issue, although an intussusception in a young child has been completely reduced. The operation in this case was not a difficult one; no undue force was used; the intestine was not injured; there was no peritonitis, and the wound showed every disposition to heal kindly. The digestion of the food and the normal motions for two days after the operation showed that the intestine was capable of carrying out its physiological functions. Yet, in spite of this, symptoms of intestinal obstruction again set in, after an interval of nearly forty-eight hours. The complete absence of any cause for the second series of obstructive symptoms leads one to refer the case to that indefinite class known as paralytic ileus. It is rare in children, but is not unusual in adults after abdominal section, and it occurs quite apart from any inflammation of the peritoneum. It is well treated by laxatives; and I regret that, as I was away for my Easter holiday when the symptoms arose, I had no opportunity of trying their effect in this case. The interest of the case centres in the light which it throws upon the vexed question of the etiology of intussusception. The child's intestine was clearly liable to paralysis, hence the original attack of intussusception. The invagination being cured, a fresh paralysis occurred, which involved the intestinal wall until it reached the neighbourhood of the irritation caused by the reduced intussusception. Here tonic contraction of the inflamed bowel occurred and symptoms of acute intestinal obstruction were again produced.

REPORTS OF SOCIETIES.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

JONATHAN HUTCHINSON, F.R.S., President, in the Chair.

Tuesday, November 26th, 1895.

THE POSSIBILITIES AS TO THE LATENCY OF PARASITIC GERMS OR SPECIFIC POISONS IN ANIMAL TISSUES, AS IN HYDROPHOBIA, ERYTHROPAS, SYPHILIS, LEPROSY, RINGWORM, TUBERCULOSIS, ETC.

THE PRESIDENT, in introducing a discussion on this subject, said that the brilliant results of experimental pathology had greatly widened our views as to the part played by micro-organisms in the etiology of disease. Generally speaking, the introduction of microbes into the host preceded by a short interval the development of specific symptoms, but in a number of instances this interval was greatly increased. The term latency applied only to periods during which no vital activity on the part of the micro-organism was going on, and did not include incubation, still less the period of prodromal symptoms. He then illustrated what was meant by latency by the example of a field in which the seeds of poppies had remained absolutely quiescent for eight years and had then grown. What evidence was there that micro-organisms could retain their vitality in a state of such absolute quiescence, and if so, what were the limits of such latency and what were the conditions governing and determining this phenomenon? The subject of latency had an important bearing on the subject of infection. What appeared to be a fresh infection from without, might in reality be due to latent micro-organisms becoming active. If the micro-organisms of tuberculous and of erysipelas could be shown to remain latent for long periods, and to be transmitted from parent to offspring, much light would be thrown on the subject of infection generally, and especially on vaccination. Thus what was generally explained as being due to a dirty lancet or to accidental infection of the vaccination wound might in reality be explained by the theory of latency. Occasionally in hydrophobia the interval between inoculation and the development of symptoms was as long as eighteen months; the period of incubation was probably always the same, but the germs remained latent before incubation began. In con-

sidering the difficult problems of latency in syphilis, it was necessary to distinguish between true and apparent latency. There were probably many children born with specific taint and individuals primarily infected who never showed any further symptoms; this was apparent latency, for in them the blood was infected, and there was a liability to tertiary lesions. If after the primary infection the secondary symptoms were delayed for two or three years this would exemplify true latency, but it was doubtful if such cases occurred. In leprosy many years might intervene between the patient leaving the country where the disease was endemic and the development of the disease. In tuberculosis much might be learnt from the study of latency as seen in disease of the skin. In the earliest stage tuberculosis of the skin might become generalised, but after this period, lasting perhaps a year, the disease became local, the bacilli were not latent but were still locally infective. This was just the reverse of cancer, where the disease at first local subsequently became generalised. But lupus apparently cured might after an interval of thirty or forty years recur close to the original lesion; this appeared to be more probably due to latent germs than to reinfection. With regard to erysipelas the incubation period of the streptococcus was short, only a few hours, and there was no evidence that this period was increased in first attacks, but it was possible that the micro-organism when once introduced remained in the tissues latent, and that at any time injury or other cause might awaken it to activity. In elephantiasis the recurrent attacks might be similarly explained. In ringworm and alopecia areata some cases of recurrence of the disease suggested the existence of latency in pathogenetic fungi.

THE BACTERIOLOGY OF LATENCY.

Dr. WASHBURN said that two points in the life-history of bacteria were of interest in connection with latency. The mode of growth of certain bacteria in broth was analogous to the varying incubation period in specific diseases: under favourable conditions growth occurred at once and rapidly reached its maximum, but with the reverse conditions the growth was deferred. The next point was in reference to the resistant forms assumed by bacteria under unfavourable conditions. Spores were well-known examples, but even sporeless bacteria were capable of producing resistant forms. As an example he quoted the pneumococcus. Probably bacteria, when latent in the body existed in this phase of their development. He believed some of the clubbed shapes assumed by the diphtheria bacillus represented resistant forms. The pathogenic bacteria protected themselves against the bactericidal influences of the body by means of their toxins. Saprophytic bacteria were devoid of this means of defence, and were easily destroyed when introduced into the body. The experiments of Wyssokowitch were quoted. Saprophytic bacteria injected into the veins of animals at once disappeared from the blood and accumulated in the organs, and in twenty-four hours were completely destroyed. The resistant spores of the hay bacillus, however, remained alive in the organs as long as seventy-eight days after inoculation. The difference between "toxic" and "septic" diseases was described. In toxic diseases the chief aim of the body was to protect itself against the action of the toxins, while in septic diseases the object was to destroy or hinder the growth of the bacteria. Both factors were present in all cases of immunity, whether natural or acquired, but either might be the principal mode of defence in either type of disease. The tissues of the fowl were poison proof to the tetanus toxin, and hence the bacilli were destroyed like simple saprophytes. In animals immunised to diphtheria and tetanus the antitoxic substances developed in the fluids of the body annulled the effects of the toxins, but had no influence over the growth of the bacteria. It was for this reason that diphtheria bacilli could remain latent in the throats of healthy individuals without producing harm. The body was poison proof, but the bactericidal properties were not sufficient to destroy the bacteria. Sometimes, especially in animals immunised to septic diseases, the bactericidal properties were much increased without a corresponding increase in the antitoxic properties. He quoted the example of hog cholera. Pathogenic bacteria, when introduced into the tissues of immune animals, were sometimes rapidly

destroyed, the pneumococcus in forty-eight to sixty hours in the experiments of Emmerich. But as a rule destruction was more tardy. A number of instances were given. Trapeznikoff found living anthrax spores in the tissues of a frog 100 days after inoculation, and Welch found living typhoid bacilli in the gall bladder of a rabbit four months after intravenous inoculation. Latent bacteria were either englobed in cells or prevented by a barrier of cells from gaining access to the rest of the body. An attempt to shut off the bacteria from the circulation was made even in the case of highly susceptible animals, as in the experiments of Werigo. In relapsing fever the spirilla were shut up in the cells of the spleen during the apyrexial stage. The reason why latent bacteria were often missed by microscopical examination might be because they were converted into forms which are not easily recognised. The transformation of cholera vibrios into oval-shaped bodies in Pfeiffer's experiments was quoted as an example. The return of activity of latent bacteria was discussed, and the investigation of Trapeznikoff and of Baumgarten mentioned; also the effect of tuberculin and mallein in awakening into activity latent tubercle and glanders. The author mentioned his own experience with latent forms of rabbit septicæmia, which were brought into activity by inoculation with other bacteria. The bacteriological evidence of latency of germs in the human body was then discussed and a number of examples given. Diphtheritic bacilli, pneumococci, streptococci, gonococci, and tubercle bacilli had been found on the mucous membranes of healthy individuals without producing any ill effects. Babes had reported a case of acute glanders, probably contracted six years previously; Schnitzler one in which the *S. aureus* had apparently remained latent in a bone for over thirty five years. Some of the cases were possibly due to a reinfection, but this interpretation was excluded in cases where living typhoid bacilli had been found in osteomyelitic foci long after recovery from an attack of typhoid fever. Several instances were quoted, of which the most notable were those of Sulian and Burohke. In the one case six years and in the other seven years after an attack of typhoid fever living bacilli were found in bone abscesses.

LATENCY OF TUBERCULOSIS.

Dr. J. KINGSTON FOWLER said that he had been asked to state as concisely as possible the pathological and clinical evidence for the belief that it was possible for the specific poison of tuberculosis to remain latent in animal tissues. The general argument adopted was as follows: (1) That the disease, having been arrested, might after a period of quiescence again become active, and that reinfection took place from within. (2) That tuberculosis might be produced by the inoculation of an animal with material taken *post mortem* from an old tuberculous lesion. (3) That the virus of the disease might pass directly from the parent to the offspring, and that in the tissues of the child it might reproduce the disease. The facts stated were chiefly drawn from cases of pulmonary tuberculosis. Reference was made to the frequent discovery of obsolete tuberculous lesions at the apices of the lungs, and to his published work on *Arrested Pulmonary Tuberculosis*. If recrudescence of the disease coincided with changes in the old lesions and recent miliary granulations were first formed around them and spread thence through the lungs the inference was that the reinfection had started from within. This would be confirmed if it should appear that the individual was in apparently perfect health until the occurrence of some symptoms pointing to the prevalence of an old lesion, for example, hæmoptysis. A case fulfilling these conditions was described. A gentleman, aged 53, had, when a boy of 13, an illness said to have been consumption. With the exception of an attack of pleurisy he had subsequently enjoyed good health. He was of good muscular development, of healthy appearance, and generally regarded as a strong man. In February, 1888, whilst in his usual health, he had an attack of hæmoptysis. A few days later some fine crackling râles were audible at the left apex. Death occurred in twenty-eight days from acute tuberculosis of the lungs. On *post mortem* examination a sharply-defined, yellow, caseous mass, the size of an olive, was found at the left apex. Its capsule had broken down at one spot, and had established a communication between the caseous mass and a bronchus;

elsewhere it was intact, firm, and fibrous. Half the mass had disappeared, leaving a small ragged cavity. Recent miliary tubercle was present throughout the left upper and lower lobes, and also in the right lower lobe. A precisely similar caseous mass was found at the right apex. It was intact and firmly encapsuled. The inference from the history was that the virus of the disease had lain dormant in the caseous mass for forty years. A case of acute tuberculous pericarditis was described in which the pericardium alone showed recent tubercle, but at the apices of the lungs old obsolete tubercle was found *post mortem*, also a calcareous bronchial gland. Tubercle bacilli were found in the pericardial lesion. The period of latency was believed to have been four years, but the case was cited to prove that obsolete lesions are capable of setting up acute tuberculosis. Attention was called to the extreme rarity of acute tuberculous pericarditis apart from general acute tuberculosis, and to the great improbability of primary infection of the pericardium from without. Dr. Sidney Martin's report to the Royal Commission on Tuberculosis was referred to, and a case was described in which inoculation of a guinea-pig with caseo-calcareous material, probably about 200 days old, had been followed by acute tuberculosis; also to some experiments by the same observer, in which inoculation with matter from old pulmonary lesions, found in the bodies of two patients dying from cancer, had not been followed by tuberculosis. Attention was directed to the importance of the dose in experimental inoculation and in infection of the human subject. The researches of Landouzy and Martin were referred to as proving that general tuberculosis may be produced by the inoculation of material from a focus, the mother being tuberculous when no obvious signs of tubercle were present in the body of the child. Straus had repeated these experiments, but without success. The theory of Baumgarten was referred to. He believed that direct transmission of the virus from parent to offspring was followed by latency in the child, and that this was the common mode of infection, that the influence of inhalation had been much exaggerated; that lesions in the fetus are absent because the number of bacilli was small; that the virus might remain dormant for long periods in the lymphatic glands and in the medulla of bones; that the tissues of the fetus possessed a special resisting power owing to the activity of cell growth. The evidence in favour of the possibility of the transmission from mother to offspring through the placenta was stated, and four cases described by Birch-Hirschfeld, Schmorl, and Kockel were narrated. In all, the case tubercle bacilli were found in the fetal placental villi, and in one in the liver of the fetus and in a lymphatic gland near to it. Three cases of mixed infection of tubercle and syphilis in infants reported by Hirschinger were referred to, and the evidence was given at length. The parents were both syphilitic and tuberculous. In all the cases there were well-marked signs of constitutional syphilis, including an eruption on the nates and snuffles. In all, the diagnosis was visceral syphilis, and the patients were shown as such at the Vienna Dermatological Society. In all, the internal lesions were found *post mortem* to be tuberculous, and not syphilitic. Tubercle bacilli were present. The reasons were stated for the belief that in these cases the infection was through the placenta and not from without. The opinion was expressed that the evidence in favour of the possibility of a tuberculous mother infecting her child was convincing, but no support was given to Baumgarten's view that this is a common mode of infection, and certainly not the most common. The evidence in favour of the possibility of a prolonged period of latency in the child after infection from the mother was considered to be at present defective, but the opinion was expressed that in the future this would be shown to be of more frequent occurrence than was at present believed. Reference was made to the further development of Baumgarten's theory, namely, that the virus might lie latent for several successive generations, and that a child might have been infected by a tuberculous grandmother, the mother having been free from the disease. Mention was made of the *périne* disease in silkworms and the inoculation experiments of Maffucci on impregnated hen's eggs, which were considered to give support to this view. The opinion was expressed that it need not be seriously con-

sidered until it had been first proved that the direct transmission of the disease from mother to offspring was an event of common occurrence, and that in such a case it was possible for the virus to lie latent for a long period in the body of the child. The shortest period of latency of the virus could hardly be determined by clinical and pathological evidence. In the inoculation experiments of Dr. Sidney Martin with milk from tuberculous cows the shortest time in which a lesion was produced in which tubercle bacilli could be recognised was nine days, and the shortest period in which general acute tuberculosis occurred was fourteen days. The conditions of the tissues and blood serum which determined latency were referred to, but it was pointed out that at present no definite statements could be made. Arrest and latency were not the same thing. The latter implied a dormant condition of a living virus. With arrest the virus might be dead. Arrest in the condition of fibrosis was the most favourable for permanence. Caseous lesions might break down if the capsule was destroyed. The resisting power of the individual depended upon the vitality of the blood. The original infection might have been an accident due to exposure to the virus whilst the vitality of the blood was low. The importance of maintaining the general health after arrest of the disease was referred to. In some cases reinfection might be due to some local change of the nature of an accident. Regret was expressed that in dealing with the latter part of the subject it had been necessary to use terms which were lacking in precision, and the hope was expressed that the discussion might elicit facts which would increase our knowledge of the conditions which determine arrest and latency.

The discussion was adjourned.

CLINICAL SOCIETY OF LONDON.

THOMAS BUZZARD, M.D., F.R.C.P., President, in the Chair.

Friday, November 29th, 1895.

CLINICAL EVENING.

RHEUMATOID ARTHRITIS.

DR. HARRY CAMPBELL exhibited a woman, aged 67, with the lesions of rheumatoid arthritis limited to the elbow-joints, though there was grating in the wrist and temporo-maxillary joints. The affection was of three years' duration. The ends of the bones were enlarged, and there was swelling of the adjoining soft parts. Upon puncture no fluid was discovered.

MENINGOCELE.

DR. HINGSTON FOX showed a female infant, aged 1 year, who had at the age of 3 months a small round tumour at the centre of the anterior fontanelle, first noticed six weeks after birth. The cranium was well formed. There was no history of injury. The tumour had grown, and now measured $1\frac{1}{2}$ inch across and $1\frac{1}{2}$ inch in height. It neither pulsed, nor was reducible, nor varied with the respiratory movements, nor was tender. The optic discs were normal. The child was intelligent, walked a little, and had four teeth.

MALFORMATION OF EXTERNAL GENITALS.

MR. J. H. MORGAN showed an infant, aged 18 months, who presented the following abnormalities of the external genitalia. On each side there was a large and well-formed mass of scrotal tissue containing well-formed testes with spermatic cord and vas deferens. These were separated from each other at their upper extremity by two well-formed penes, which measured about three-quarters of an inch in length, the left being rather longer than the right. In each the frenum was absent, and the corona was but slightly marked. There was no urinary meatus in either. Each was attached to the ramus on either side, the pubic rami and symphysis being apparently normal. Below the root of these two organs was another prominent mass of tissue about three-quarters of an inch in length, consisting of a pouch of skin and subcutaneous tissue, in the centre of which was a firm and more fibrous body, which was attached immediately below the two penes, lying midway between the two scrotal prominences, there being a deep sulcus on each side between it and these. Posteriorly to this finger-like process was a mass of skin and subcutaneous tissue covered by epithelium resembling that of skin, except upon its posterior surface, where it was more

like mucous membrane. This projected forward about half an inch, and looked like a small mamma, on which was a prominent bluish nipple. The left part of it was a small pedunculated body which stuck out like a small pen, and was attached to the finger-like body. Below this, lying in the middle of the perineum and in front of the anus, was a prominent mass of mucous membrane measuring about $1\frac{1}{2}$ inch from before back, and $3\frac{1}{2}$ from side to side. This was very red and vascular, and protruded when the child cried. Along its right attachment was a slit about half an inch long which admitted a probe into a long narrow cavity passing vertically upwards for about 2 inches, in which the probe could not be moved laterally. This was evidently the mucous membrane of the bladder, as the urine drained from this surface when the child was at rest, and was driven in jets when it cried from the orifices of the ureters, which could then be seen. Behind this protruding mucous membrane lay the anus, which easily admitted the little finger, but no abnormality could be detected in the rectum. The child presented no other abnormality except that at the upper part of the lobule of each ear there was a small fibrous prominence. Nothing abnormal could be discovered on auscultation of the heart, but the limbs became much cyanosed when the child cried.

CHARCOT'S DISEASE OF JOINTS.

THE PRESIDENT showed a woman, aged 38, with symptoms of tabes dorsalis. Twenty months ago the right foot became severely swollen, without pain. The mobility of the tarsal joint was interfered with, and the joint contained fluid. Six months ago the whole left lower extremity became enormously swollen after unwonted exercise, again without pain. At present the left knee was greatly enlarged, and its ligaments were lax. It was probably an early stage of Charcot's disease, and of the class described by Charcot as benign.

DR. SANSON said that here there was absence of pain; he asked if the President had seen any cases that more closely resembled rheumatoid arthritis, being accompanied by much pain.

THE PRESIDENT could call to mind one or two cases in which there was some pain, but none with much pain.

MYOSITIS OSSIFICANS.

MR. S. PAGET showed a child, aged 5, without first phalanges in its great toes, the ungual phalanges articulating with the dorsal surface of the metatarsal bones. The thumbs were normal. The pectoral muscles were ossified at their insertions, the latissimi dorsi and the sterno-mastoids were also partly ossified. A lymphatic vessel in the axilla was ossified for 3 inches. There was an ossified node on one rib, and one at the centre of the forehead, the latter produced, perhaps, by falls. There was no history of like disease, or of any rheumatic or gouty affection in the family.

TWO CASES OF DEFICIENCY OF TIBIA.

MR. CLUTTON showed a boy, aged 15, who had no tibia, the fibula being the only bone in each leg. The foot had only three toes articulated at right angles with the fibula. There was unusual development of the condyles of the femur which were usually pointed in the absence of the tibia. The patella was well formed. Both hands were bled, two fingers were absent from each hand, and the metacarpal bones on each side of the cleft were fused together. The boy was able to separate the digits to an abnormal degree. Mr. Clutton also passed round a photograph of similar deformity in another boy, who also had deficiency of fingers. The other patient he showed was a girl, aged 8, whose feet were at right angles with the fibula. The patella was small. One foot had four and the other five toes. She could get about with great facility, either by a sort of amble or by short jumps.

LIGATION OF FEMORAL ARTERY AND VEIN FOR SECONDARY HEMORRHOGE.

MR. C. S. WALLACE showed a man, aged 29, who had fallen a distance of 20 feet on to railings, and had driven an iron spike 6 or 7 inches long into the inner side of his thigh, where, having broken off, it remained compressing the femoral artery and vein, though the femur was not broken. The removal of the mass left a huge cavity, with the artery and vein running in front of it. The wound became septic, and

five days subsequently the artery gave way. It was ligatured above and below, and 3 inches of it were removed. The vein also gave way, and was ligatured in two places, and the vessel between was removed. The man had made a perfect recovery, and pulsation in both the anterior and posterior tibials could now be felt.

Mr. MAKINS said that a large part of the man's trousers was driven into the wound with the iron spike; the wound was therefore septic, and the case was something more than ligature of the artery and vein alone, and it was very encouraging.

Mr. THOMAS SMITH said that not many years ago a thigh with such a severe wound would always have been amputated; that was the rule. It was astounding what might sometimes be done in the removal of vessels. He had lately taken away the superficial femoral artery and vein, and the profunda vessels (artery and vein), in the removal of a tumour, and two months afterwards the circulation in the foot had been re-established, and the man had returned to his work.

MODIFIED INCISION FOR REMOVAL OF THE VERMIFORM APPENDIX.

Mr. BATTLE showed a patient, aged 18, on whom he had operated for recurrent appendicitis. He had modified the usual incision in order to prevent the subsequent formation of a hernia, which was so frequent a sequel of this operation. He made the incision $\frac{1}{2}$ inch to the inside of the linea semilunaris, and divided the aponeurosis of the external oblique with the sheath of the rectus. The rectus muscle was then drawn to the inner side, and the posterior layer of the sheath and transversalis fascia exposed, the inner incision not corresponding to the external. The peritoneum was then divided. He was able to get at the appendix very well through this incision, and the result appeared to him to justify the slightly longer time it took. The layers were sutured from behind forwards, and as the rectus was allowed to return to its place, it thus interposed between the internal and external wounds in the abdomen. The procedure seemed, he thought, to hold out better hope of avoiding subsequent hernia.

Mr. CLUTTON said it mattered very little where the incision was made provided (1) it was not in the line of fibrous aponeuroses, but went through the muscular layers, and (2) that the line of union was made by stitching together the two sides of each layer incised, namely, peritoneum, fibre, muscle, and skin, and never to adjoining layers. He had now for two years past seen no hernia follow these operations, though he had watched for it carefully in many cases. An American operator advised that the muscular structures should be divided in their length, so as to be as little damaged as possible.

Mr. BARKER always now made the incision through the muscles, and never of recent years had seen a subsequent hernia. It was also important that the cut should be as small as possible, as well as through muscle, and that the surgeon should get to the appendix by the most direct route, wherever that might be.

Mr. BATTLE, in reply, said that this incision did absolutely prevent hernia. He had seen in several cases the formation of hernia after the usual operation, though the patients were perhaps unaware of it.

LIGATURE OF BOTH EXTERNAL ILIAC ARTERIES BY THE TRANSPERITONEAL METHOD.

Mr. MAKINS showed a man, aged 34, who came to him three years ago with a large ilio-femoral aneurysm. As he could not be sure of being able to ligature the external iliac artery, he made his incision through the semilunar line, not exclusively through fibrous tissue, and managed to ligature the external iliac artery. The patient was up and about by the forty-seventh day. Within three months he came back complaining of pain in the groin on the opposite side, where there was a pulsating swelling not so large as the previous one. He took it to be due to gummatous arteritis, and repeated the operation. This time he recovered much more rapidly than on the first occasion, the collateral circulation being established more promptly. This he attributed to the ligature of the other external iliac artery having dilated the

vessels to some extent. He mentioned that at the first operation he had tied the epigastric artery because it led directly into the sac. The patient had worn a belt ever since and had no hernia, though he was a carpenter and worked hard.

Mr. THOMAS SMITH asked the author which operation, if he were quite free to choose, he would adopt for ligature of the external iliac vessel.

Mr. MAKINS, in reply, said the operation through the peritoneum was the easier; but if quite certain he could get at the artery without wounding the peritoneum he would prefer the other method. He was not sure of being able thus to ligature the artery in the first instance, and later, as the patient had previously done very well, he repeated his first procedure.

PRECOCIOUS PUBERTY.

Dr. HARRY CAMPBELL showed a lad, aged 14, who had been under observation for upwards of ten years. When he was only 15 months old his mother noticed that hair was beginning to grow upon the pubes, and that the external genitals were abnormally large. At 2 years of age they were fully developed, and had not materially altered during the last ten years. He had from the 4th to the 7th year manifested great sexual excitement, and had frequent discharges of seminal fluid, but Dr. Campbell had never been able to satisfy himself of the presence of spermatozoa. Since then the sexual excitement had been less, probably in consequence of large doses of bromide. The boy's muscular development was remarkable, in fact, he had the thigh and trunk muscles of a man of 25 or 30. He had been in the habit of being shaved for some years past. His education was defective, because no school would ever take him in.

HARELIP, CLEFT PALATE, ETC.

Mr. MORGAN showed a child, aged 3½ years, with well-marked harelip and cleft palate, together with defective development of the left side of the face, and abnormal formation of the left external ear, on which was an auricular appendage. In addition, he presented a curious band of skin on the left side, in which no muscle could be felt. On the opposite side the trapezius was hypertrophied, and there was a large mass of bone, probably representing a rotated cervical vertebra. The author had endeavoured to unite the palate, but had been obliged to desist by the hæmorrhage. The patient was not a bleeder. The soft palate had united well; and Mr. Morgan was about to try to unite the cleft in the lip.

MEDICAL SOCIETY OF LONDON.

Monday, November 19th, 1895.

Sir J. ORRINGTON BROWN, M.D., F.R.S., President, in the Chair.

THE OPERATIVE TREATMENT OF CLEFT PALATE.

Mr. EDMUND OWEN briefly reported the cases of five children on whom he had operated for cleft palate in the spring and summer of this year. The operations had been performed in the St. Helena Home, St. John's Wood, which had the great advantage of being surrounded by a garden into which the children were got almost directly after the operation. His opinion was that cases of this sort did much better in private than in hospital practice, probably because they enjoyed the great advantage of fresh air. He advocated early operation in all cases that were physically fit for it, and he emphasised the importance of having carious teeth, adenoids, and enlarged tonsils cleared out before operation was undertaken. In one of the cases reported a cleft of the soft and of the back of the hard palate was successfully operated on in an infant of 8 months. In another child of 2 years, with a complete cleft which extended through the left intermaxillary bone, operation also proved entirely successful. In another of the cases, a girl aged 6½ years, with a cleft which at the back of the hard palate measured $\frac{1}{2}$ inch wide, only a partial success was obtained. In the remaining cases, however, the clefts were entirely obliterated. Mr. Owen deprecated the use of a nasal tube for feeding cases after operation, and stated that he preferred beef jelly to milk for the first few days, as it slipped down easily, and did not form hard clots in the stomach which was likely to be irritable

after the prolonged operation under chloroform. All his operations had been done under chloroform, which had been administered by Mr. Davis, partly by a mask and partly by a Junker apparatus. The children were laid on their backs, with the head extended and hanging down over the end of the table. Mr. Owen was strongly of opinion that operations for cleft palate should be performed by preference in the spring and summer, as the light was good, there were no fogs or cold east winds, and no catarrhs or cough, and, moreover, the children could be kept out in the fresh air from the moment that they had recovered from the shock of the operation. He passed round a water-colour drawing of the pharynx of the girl with the $\frac{1}{2}$ -inch cleft (made by Mr. A. W. Sanders, of St. Mary's Hospital), which showed an enlarged Luschka's tonsil and a crop of post-nasal adenoids. These growths he had cleared away before attempting to close the palate.

Mr. JOHN H. MORGAN said his experience of operating on very young subjects had not been altogether satisfactory, and he did not think the operation could advantageously be undertaken before the expiration of the twenty-fourth month. He added that a child could not have contracted any marked imperfection of speech before 2 years of age, and, moreover, with careful training such defective speech might be prevented for much longer. He agreed that operations in private practice were more successful than those done in hospitals.

Mr. CLETON said the question as to the age at which patients could be operated upon had less to do with the fact of the cleft involving both the hard and soft palate than with the height of the palate and the thickness of the tissues. In an arched palate the flaps could be brought into position without undue tension, but it was quite otherwise in cases in which the palate was horizontal. He himself had operated on several children under 12 months, and he made a point of doing it under 2 years. The voice improved even when the operation was delayed until 25 or 26 years of age, as in two cases of his own; but that, of course, would depend greatly on the antero-posterior diameter of the palate, which might be too short to catch the vibrations. He did not approve of silver wire sutures, he himself using fishgut and horsehair. He had never had any trouble with the tongue, and did not consider that any precautions were necessary in this direction. He insisted on the necessity of making special incisions for the purpose of ensuring an absence of tension. He was very careful to remove the stitches, often giving an anæsthetic for the purpose.

Mr. D'ANCY POWELL said he had operated by the flap method during the preceding week, and there was disquieting tension on the stitches.

Mr. DAVIES-COLLEY said he preferred 14 months of age for the operation. His flap method rendered it almost absolutely sure that union of the hard palate would take place. He had been less successful in procuring union of the soft, as well as of the hard, palate at the same time. In two recent cases he had succeeded in obtaining complete union of the hard with partial but incomplete union of the soft palate. A third case had proved a failure. He insisted on the fact that he did not exclusively employ the flap method, but in young children he thought it was much more certain. In conclusion, he insisted on the desirability of early operation in these cases, not only to avoid defects of speech, but also to prevent the deformity of the face which otherwise resulted.

Mr. W. ARBUTHNOT LANE insisted on the importance of having plenty of room to work in, to obtain which he himself would not hesitate to divide the united lip if necessary.

Mr. WALSHAM advised leaving the paring of the edges until the end of the operation, and free lateral incision in order to prevent tension.

Mr. KILLOCK observed that it was well to leave the children in hospital at least a week in order for them to become accustomed to their surroundings, and he insisted on the necessity of a close search for other abnormalities prior to operation. He disapproved rectal feeding.

THE DISTRIBUTION OF MOTOR AND SENSORY SYMPTOMS AFTER INJURY TO THE BRACHIAL PLEXUS.

Dr. BRYN described two cases of injury to the roots of

the brachial plexus. In the first case a man, aged 25, was caught by the right hand in the strap of a gas engine, and thrown off his feet on to his back, two years ago, and was paralysed directly after in all the muscles of his right arm excepting the small muscles of the hand and the flexors of the thumb and fingers; and when seen three months later he had lost some power in the latissimus dorsi, serratus magnus and pectoralis major—and lost sensation along the outer surface of the arm and forearm, extending from the shoulder to the hand, and involving the thumb, including the thenar eminence and the posterior surface of the index and its metacarpal bone. In the other case a man, aged 40, was last June pitched off a hay cart on to his right shoulder and side of head, and experienced violent pain and lost power in the right upper limb in all the muscles except the small hand muscles, and the flexors and extensors of wrist, with anæsthesia along the outer surface of the limb, but less extensive than the former case, and not involving the index finger. The lesion was considered to be in the cervical roots of the brachial plexus. The muscles affected when compared with the lists of other authors of the cervical roots, were such as would be caused by a lesion of the fifth, sixth, and seventh cervical in the first case, and of the fifth and sixth cervical in the second case, and these roots were considered to have been damaged. The prognosis was considered to be much better for lesions of the roots than of the cord, so that treatment could be persevered with in the former, with a hope of recovery even two years after the injury. The distribution of the muscles supplied by a root of the brachial plexus was considered to be of an anatomical and not a physiological nature.

BRITISH GYNÆCOLOGICAL SOCIETY.

CLEMENT GODSON, M.D., President, in the Chair.

Thursday, November 14th, 1895.

A VERY LARGE OVARIAN TUMOUR SUCCESSFULLY REMOVED. Mr. SKENE KEITH showed a tumour, weighing over 100 lbs., successfully removed from a patient aged 55. The tumour was first noticed eleven years ago; for some time it appeared so like a fibroid tumour that seven different physicians in London, consulted during the first few years, pronounced it to be fibroid, and advised that no operation should be done. Lately it had grown much, and Mr. Keith saw her. She was then confined to bed, and could only lie on her back. Owing to the size of the abdomen she could not raise her thighs, and no vaginal examination was possible. Her general condition was not very good, and the pulse was intermittent. He therefore first tapped the tumour, drawing off over 75 lbs. weight of fluid. Ovariectomy was performed a few days later. For a week after operation there was considerable shock, and the cardiac condition was so bad that she required digitalin in $\frac{1}{2}$ gr. doses every two hours for the whole of that time. It was now six weeks since the operation, and the patient was doing well.

The President observed that the weight of the tumour was equivalent to fourteen babies at term.

Dr. LEITH NAPIER and Mr. GEORGE KEITH also spoke.

SPECIMENS.

Dr. HEYWOOD SMITH showed a specimen of Ectopic Gestation at four months. The patient, aged 38, had four children, the youngest six years and a half before. The history was that of a miscarriage, and when seen by Dr. Heywood Smith there was a tumour nearly filling the pelvis. Abdominal section was performed and the gravid tube and foetus removed. The patient made a good recovery. Dr. F. W. BURN, who had examined the specimen, reported that the placenta was enormously enlarged by hæmorrhage into its substance. There was a curious division of the head of the foetus to the umbilicus. Dr. LEITH NAPIER showed a Uterus with Mucopurulent Endometritis becoming sarcomatous removed by vaginal hysterectomy.

A CASE OF PORRO'S OPERATION FOR LABOUR COMPLICATED BY UTERINE FIBROID.

Dr. MORTON NOTTINGHAM read this paper for Dr. GEORGE ELDER (Nottingham), who was unable to be present. The

patient was a primipara, aged 35 years, and the fibroid had not been observed till labour set in. The tumour occupied the pelvis, jamming the lower segment of the uterus against and above the symphysis pubis. An attempt to elevate the obstruction was quickly found to be useless, and Porro's operation was performed the same afternoon. The child was delivered alive. The stump of the uterus was treated in the ordinary extraperitoneal fashion and a drainage tube inserted. The patient made a good recovery. Inquiry showed that there had not previously been any suspicion of pelvic mischief; hence it was probable that the changes brought about by pregnancy had so stimulated the growth of the tumour as to bring about the grave evil which rendered the above operation necessary.

The President observed that less was heard latterly about Porro's operation because of the success of Caesarean section, especially in the hands of some well-known operators. He performed what he believed to be the first successful Porro's operation in this country; nevertheless, he would now choose to do the Caesarean section if the nature of the case allowed it. Although fibroids took on increased growth during pregnancy, it was possible for one to attain a considerable size without being discovered. Thus it had more than once occurred to him to find one for the first time when he put his hand on the abdomen after labour to feel whether the uterus was contracted.

Dr. ORICHTON (Twickenham) said he remembered a case in which he turned a child, and then found a fibroid the size of a flat which had not been observed before. It apparently disappeared during involution, for in a subsequent pregnancy it could not be found.

Drs. MACNAUGHTON JONES, HEYWOOD SMITH, and LEITH NAPIER also spoke.

UNUSUAL COMPLICATIONS IN TWO CASES OF REMOVAL OF THE OVARIES AND FALLOPIAN TUBES.

Mr. SKENE KEITH read this paper. The first case was one of a patient, aged 32, suffering from chronic disease of the appendages, which had greatly reacted on the general health. At the operation, when the right ovary had been freed of adhesions and removed, it was found that there was a distinctly localised, irregular swelling, as large as a hen's egg, behind the head of the colon. His hope was that it was inflammatory; his fear that it was sarcomatous. Six months later there was no swelling to be felt on examination, but there was a little tenderness. This also had disappeared two months later. The second patient was aged 35. Three years ago, after an abortion, she had "inflammation in every organ of her body," as she expressed it. Pain in the right side caused her to walk as if lame; an unusual symptom was that as soon as she took food she invariably and immediately felt nauseated. The right-sided pain occupied two distinct areas, the one in the usual position of a pain caused by disease of the ovary, the other in that caused by disease of the appendix. At the operation the appendix, though healthy, was closely involved in a mass of adhesions round the enlarged ovary and tube of the right side. The feeling of nausea disappeared at once, and six months later the patient was in perfect health.

GLYCOSURIA COMPLICATING AN OVARIAN TUMOUR AND OVARIOCTOMY.

This paper, by Dr. J. HALLIDAY CROOM, was read, in his absence, by the SECRETARY. The patient was 53 years of age, and had noticed an abdominal tumour for five months. Being excessively corpulent the early growth was probably masked. When she presented herself at the Royal Infirmary, Edinburgh, her appearance was extraordinary. Her height was 5 feet 4½ inches; her weight, without clothes, a little over 17 stone; and the girth of the abdomen 60 inches. Her complexion was pale, lips cyanosed, with a distinct growth of hair on the upper lip and chin. The urine was not increased in quantity; its specific gravity was 1047, and it contained blood, a little albumen, and much sugar. Urea normal or diminished. All other signs and symptoms of diabetes were absent. It was regarded as a case of glycosuria, probably caused by the tumour. Codeine and morphine had no effect on the amount of sugar. Laparotomy was performed as the growth was increasing and the

dyspnoea urgent. There was found a colloid tumour implicating each ovary; the two together weighed 55½ pounds. The sugar remained practically unaltered after the operation for eleven days. At the end of this time a course of morphine was resumed, which had an immediate effect in reducing the quantity. After ten days the morphine was stopped, and the diet rigidly restricted. For a fortnight no difference was observed; then there was a rapid diminution. Ten days later she was sent home, the urine containing a mere trace of sugar. Two months later a specimen was examined and found to be quite free.

The etiology of the glycosuria was then discussed.

Dr. MACNAUGHTON JONES considered pressure on the portal vein a likely cause of the glycosuria. He thought the hepatic a more likely explanation than the pancreatic, though both might coexist.

Dr. LEITH NAPIER suggested that there were two classes of causes of glycosuria—the mechanical and the nervous. Disturbance in these factors caused variations in metabolism. Morphine and its allies answered well in diabetes, but in glycosuria the group of the bromides was much more efficacious.

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.

Thursday, November 14th, 1895.

J. DRUMMOND, M.D., President, in the Chair.

TREPHINING FOR JACKSONIAN EPILEPSY.

Mr. A. E. MORISON showed a patient who had been trephined for Jacksonian epilepsy. A sailor, aged 31, in September, 1893, without previous illness or warning lost the power in his arm up to the shoulder, and felt some weakness in his leg. Ten days later vomiting commenced, and three weeks later he had severe headache and fits. The fits began in the right toe with a gripping feeling, and spread up the leg. Then the arm became affected, and finally the head and neck. The aura was followed by clonic spasms in the same parts. He was first seen in January, 1895, and the following conditions found: He had headache, but not constant. It came on before the fits, and lasted six or seven days after. The pain in the head was over the fissure of Rolando, and tapping aggravated it. His speech was unimpaired; memory slightly defective. His vision was impaired, and he had well-marked double optic neuritis. His arm and leg were feeble; he had scarcely any grip with his hand, and could only walk with difficulty on account of weakness of the leg. There were scattered anæsthetic areas in the arm and leg. The reflexes were exaggerated on the right side. He had previously been trephined without benefit. The operation was performed on January 10th, 1895. The trephine was first applied between the arm and leg centres, and there the brain pulsated. Another disc of bone was removed over the arm and face centres. Here the bone was firmly adherent to the dura mater, and there was no pulsation. Around this spot the bone was chiselled away till a pulsating ring surrounded the non-pulsatile portion. The dura was then opened, when the arachnoid, distended by fluid, bulged. This was incised and about 2 ounces of clear fluid escaped. A finger introduced into the cavity found this closed on every side. An encysted subarachnoid collection had been opened and emptied. The wound was entirely closed without drainage. Recovery was uneventful. Fits and optic neuritis had disappeared; vision was so little impaired that he could read ordinary print. His hand had recovered its grip; he could walk well with only a slight halt, and could earn his own living. In connection with this case Mr. A. E. Morison showed on the skull a simple and satisfactory method of mapping out the fissure of Rolando, which he had worked out. The first point to fix was the upper end of the fissure, half an inch behind the centre of a line drawn from the glabella to the occipital protuberance. This point formed the apex of an isosceles triangle, the first side of which lay in the middle line, and the second ran downwards and forwards, and each measured 3½ inch, the base 4½ inches. It was demonstrated that this method, quickly and easily applied, led to the same result as more complicated and difficult measurements.

WIRING OF THE PATELLA IN A MYXEDEMATOUS PATIENT.

Dr. GOWANS showed a patient suffering from myxedema whose patella had been wired for recent fracture. The patient had been exhibited at this Society many years ago as a rare though well marked case occurring in a man. He had undergone at intervals irregular treatment by thyroid feeding, with improvement, though the evidences of myxedema were still distinct. In walking along the street he fell violently on his knee, and sustained a simple fracture of the patella. There was great swelling from effusion of blood and fluid in the knee-joint, and the fragments were separated 3 inches. Six days after his accident the patella was wired through a vertical incision, and no drainage was employed. The result could be seen to be quite perfect. Dr. Gowans expressed an opinion that operative treatment should be the rule in fractured patella.

REMOVAL OF A HÆMORRHAGIC OVARIAN CYST.

Dr. GOWANS showed a woman, aged 28, who came to him with a painful tumour connected with the uterus and fixed in the left fornix. On removing it and finding bloody contents he at first thought of extrauterine pregnancy, but a careful examination showed that the thickened tube was not involved in the swelling, which was an ovarian cyst filled with blood.

ECTOPIC GESTATION.

Dr. GOWANS showed a married woman, aged 27, and the mother of three children, the last born three years before her illness. Menstruation ceased in March, 1895. Early in May, after severe cramping pains, she had vaginal hæmorrhage. She considered herself pregnant. From that time there was more or less hæmorrhagic discharge. On May 25th she had a bad attack, fainted, and became collapsed. On May 28th Dr. Gowans saw her, and found a tumour in the middle line in front of the lower abdomen. On vaginal examination a large fluctuating painful mass was found in Douglas's pouch. The os was soft and open. The patient was so ill that no operation could be undertaken then. She afterwards rallied somewhat, but, though in desperate plight, was submitted to operation in the first week of June. The abdomen was quickly opened and emptied of blood and clot, in which floated a three months' foetus. The sac was drawn out and cut off, and the cavity left plugged with gauze and drained by a tube. The tube was removed in forty-eight, and the gauze in seventy-two, hours. The patient, though very ill for a few days, is now in perfect health. In connection with this case, Dr. Gowans exhibited another specimen of extrauterine foetus with its sac which he had removed by operation, and commented upon the very great importance of diagnosis in this class of case.

CASES OF EXTENSIVE OPERATIONS ON THE GENITALS.

Mr. PAGE showed the following cases: (1) A man who had been brought before the Society a month before with Epithelioma of the Penis, Scrotum, and Inguinal Glands, and now produced him after operation. The inguinal glands on both sides, the penis, scrotum, and testicles had all been removed, and the wound was almost healed. The man's existence had, at least for the time, been made tolerable. (2) A girl of 6, convalescent, and a Solid Ovarian Tumour weighing 9½ lbs. which had been removed from her abdomen. Microscopically the tumour was fibro-sarcoma. So far as could be ascertained by Mr. Page this was the youngest child who had recovered after removal of a sarcomatous ovary.

RADICAL CURE OF INGUINAL HERNIA.

Dr. HUME showed an interesting collection of cases, not selected because of their success, but to bear out his statements. He had written to twenty-six patients operated on in his ward, and asked them (1) if there were any recurrence, (2) if they wore a truss, and (3) if they would come to-night. Of the twenty-six patients nineteen replied; of these, eight were cases operated on by Halsted's method. There were four recurrences; two were done by MacEwen's method, one recurred. Nine were done by the ordinary operation (removal of sac and stitching canal and pillars of ring); all were cures, but two wore a truss. Dr. Hume then described the different methods, detailing his objections to each, and pointed out his conclusions—namely, that failures arose chiefly from the

stump of the sac being left to occupy the internal ring, and that the most important item was to close satisfactorily the internal ring.

PHELPS'S OPERATION FOR SEVERE CLUB FOOT.

Mr. BLACK showed a boy, 6 years of age, with photographs of his foot before operation. The patient now walked well without deformity, and the photographs, taken before operation, showed a high degree of talipes equinus varus.

CLINICAL SOCIETY OF MANCHESTER.

A. WAHLTUCH, M.D., President, in the Chair.

Tuesday, November 19th, 1895.

PRESIDENT'S ADDRESS.

THE PRESIDENT delivered a short opening address, pointing out the advantages to be derived from the Society, the steady increase in the number of its members, and from the published annual reports enumerating the cases of interest which had been brought before the Society in past years.

HYSTERECTOMY FOR UTERINE FIBROID.

Dr. LLOYD ROBERTS showed a specimen of a fibroid tumour of the uterus, weighing 3½ pounds, removed by abdominal hysterectomy from a woman aged 22. Menstruation had been normal. The tumour was composed of two almost spherical masses, the larger of which represented the body of the uterus and was fixed in the cavity of the pelvis, the smaller an outgrowth extending into the right broad ligament, reaching as high as the umbilicus, somewhat movable and in consistency it felt like a tense cyst. For three weeks before operation the patient had been suffering from retention of urine which required catheterisation. Abdominal hysterectomy was performed on August 7th, 1895. The right broad ligament was tied at its base—that is, below the smaller swelling which had distended the mesosalpinx. The cervix uteri was small, forming the pedicle. The raw surfaces of the pedicle were covered in by peritoneum, silk sutures being used. The uterine stump was returned into the pelvis and a drainage tube inserted. The patient was discharged from St. Mary's Hospital on September 21st, 1895. Dr. Roberts drew attention to the following points: (1) The apparently cystic nature of the upper swelling; (2) the normal menstrual history; and (3) the youthful age of the patient.

CANCERUM ORIS.

Dr. HUTTON exhibited a large sequestrum removed from a girl, aged 4, who had suffered from cancerum oris. The sequestrum included practically the whole of the dental process of the left superior maxilla, with part of the dental facial processes. The disease arose during convalescence from an attack of measles complicated with pneumonia. The child was also shown.

MISCELLANEOUS.

Dr. HILL GRIFFITH showed and briefly commented upon the following: (1) A middle-aged woman with Sympathetic Disease, following five weeks after rupture of the sclerotic at the ciliary region, with subconjunctival dislocation of the lens. Enucleation had been urged, but declined. (2) Large recent Rupture of Eyeball, in which enucleation was to be done. (3) Two cases of advanced and rapidly progressive Exophthalmic Goitre in young men.

PATHOLOGICAL SOCIETY OF MANCHESTER.

H. R. HUTTON, M.A., M.B., President, in the Chair.

Wednesday, November 17th, 1895.

CONGENITAL HEART DISEASE.

THE PRESIDENT showed the heart from a case of congenital heart disease in a child 6 months old. The malformations consisted of: (1) Patency of the foramen ovale and ductus arteriosus; (2) incomplete formation of the septum between the ventricles; (3) dilatation of the aorta, from which vessel it was probable the pulmonary arteries arose; (4) thickening and small vegetations about the tricuspid orifice (fetal endocarditis).

GLIOMA OF THE PONS.

The PRESIDENT also showed the brain and microscopic

sections from a case of glioma of the right side of the pons pressing on the medulla) occurring in a girl, aged 14. The symptoms had been observed for only eleven weeks, and consisted of right internal strabismus, optic neuritis (latterly), loss of power of co-ordination, and slight varying rigidity of the limbs.

ORBITAL TUMOUR.

DR. EDWARD ROBERTS and Dr. J. GRAY CLUGG showed a tumour removed from the orbit of a girl, aged 15. The tumour, of the size of a nutmeg, was situated under the angle of the orbit, was enclosed in a firm capsule, and was easily removed. Its structure was that of a spindle-celled sarcoma, with large lymph spaces running through it.

MISCELLANEOUS.

Dr. WILLIAMSON showed (for Dr. DIBSCHFELD) preparations from a case of Acromegaly, and also exhibited a patient suffering from the disease.—Dr. KELYNACK showed specimens from a case of Intestinal Obstruction, due to Distension of a Cancerous Gall Bladder.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH OF THE BRITISH MEDICAL ASSOCIATION.

A. H. CARTER, M.D., F.R.C.P., President, in the Chair.

Thursday, November 15th, 1895.

ENLARGEMENT OF THE LIVER.

Dr. FOWELL read a paper on this subject. He said the chief causes of enlarged liver were alcohol, cardiac debility (for example, after industrial, valvular disease, bronchitis and emphysema, phthisis, syphilis, gout, diabetes, gall stones, apæstic fevers, abdominal catarrh, leucocythæmia. The methods of detecting this morbid change, and the efficiency of these, were referred to. The frequency of the condition and the varieties of its morbid anatomy were mentioned. The condition of the spleen, with especial reference to those cases where it was notably increased in size, was described. Finally, therapeutic suggestions were made.

The paper was discussed by the PRESIDENT and Drs. RICHARDS and JENNIAL.

Dr. FOWELL replied.

BLOOD CYST IN THE ABDOMEN, PROBABLY OF TRAUMATIC ORIGIN.

Mr. BARLING read a paper on this subject. He related three cases: 1. Blood cyst over right kidney appearing eighteen months after an injury (this contained 0.5 urea). 2. Blood cyst (mesenteric) noticed some months after an injury (it contained neither urea nor proteolytic ferment). 3. Blood cyst containing a proteolytic and starch-converting ferment, and probably connected with the pancreas. The use of the term "pancreatic cyst," and their locality and origin was briefly discussed; the fate of these blood cysts if left untreated was pointed out; the treatment to be adopted—incision and stitching the opened cyst to the abdominal incision—was described; and the disadvantages of aspiration, of injection, and of enucleation were referred to.

Dr. MALET read a note of one similar case.

The papers were discussed by Mr. MARSH (who related a case), Mr. LEBHAM GREEN, and Dr. BART.

Mr. BARLING replied.

COMPLETE ABDOMINAL EXTIRPATION OF THE UTERUS AND APPENDAGES.

Mr. JOHN W. TAYLOR showed a large myoma of the uterus, which he had removed three months previously by the operation of complete abdominal extirpation of the uterus and its appendages. This operation afforded a thorough and successful method of dealing with a case in which the older surgical methods were inapplicable. The pelvis was blocked by the tumour; and when this was the case, simple removal of the appendages was often unsatisfactory, and the clamp operation was inadmissible. The patient, who had suffered from severe attacks of hæmorrhage before the operation was done, had made a good recovery, and was shown.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF SURGERY.

Sir W. THORNTON STOKER, F.R.C.S.I., President, in the Chair.

Friday, November 8th, 1895.

COLOCTOMY.

Mr. WHEELER read a communication upon colotomy, in which he reviewed the numerous conditions requiring the operation of colotomy. He strongly recommended it prior to excision of the rectum for cancerous disease in cases where the subject of the contemplated operation was suffering from much rectal irritation, diarrhoea, pain, and consequent nervous exhaustion, in order that the irritated bowel might get rest and also improve the constitutional powers. He referred to the selection of the operation being sometimes optional with the operator, and considered anterior colotomy preferable and safer, although not excluding the lumbar operation, which had its own place in surgery. Reference was made to the frequency of the peritoneum surrounding the entire gut, and, in consequence, one of the advantages claimed for the lumbar operation could not always be upheld. He recommended the parietal peritoneum to be sutured to the wound, and a needle armed with a suture passed through the mesentery, and then carried through the parietal peritoneum on each side; the gut having previously been drawn through the wound, he sutured back the mesentery at the distal side of the gut to the parietal peritoneum sufficiently to prevent protrusion, which plan was much preferable to drawing the intestine in quantity outside the abdomen and ultimately cutting it off, a procedure sometimes inadmissible. When there was a short mesentery, in addition to the above he passed a sterilised bougie through the mesentery below the suture, and allowed it to rest across the wound external to the abdomen; this helped in the formation of a more perfect spur, so essential for the after-comfort of the patient. He deprecated the division of the gut and suturing the lower end and then dropping it into the abdomen, enumerating the disadvantages and dangers. He recorded cases only of which he had authentic notes and histories; amongst the number there was one transverse colotomy for obstruction at the splenic flexure of the colon ascertained by an exploratory incision, believed at the time to be malignant, the patient now being alive and well, nearly three years after the operation. He also described a left inguinal colotomy for cancerous prostatic disease causing obstruction; the patient died thirteen months after the operation. The other colotomies related were for congenital deformity, malignant tumour, cancer of the rectum, and acute obstruction.

LUMBAR COLOCTOMY.

Mr. HENRY GRAY CROLY read a paper on left lumbar colotomy, and stated that he had, during the past twelve years, performed that operation eighteen times. With one exception, the operations were performed for cancer of the rectum, and the cases were unsuited for excision; no death occurred from the operation. Two of the patients (notwithstanding careful antiseptic precautions) were attacked with erysipelatous inflammation and septic or erysipelatous pneumonia, but recovered. In each case great relief was afforded to the sufferers. The patients lived from a few months to over two years; one man worked for nearly two years after the operation as a Corporation labourer. All the patients got fat and expressed themselves gratefully for the relief afforded to their sufferings. Mr. Croly said he did not intend to compare the lumbar operation with the now more fashionable inguinal operation, but thought it his duty to place on record brief notes of the cases. He described his method of operation and after-treatment, and claimed for lumbar colotomy its extraperitoneal advantage, and he considered the position of the artificial anus in the loin less disgusting to the patient than the inguinal.

The PRESIDENT expressed surprise that lumbar colotomy should be advocated at the present time. Mr. Bryant's name had been brought forward as supporting it. He did not agree with Mr. Bryant's views with regard to lumbar colotomy. Mr. Wheeler sutured the peritoneum to the skin. He found that a much better anus was formed if this

was not done, but the bowel was allowed to join the muscular and fibrous coat as well. He thought that in some cases the gut might be cut across, and so any chance of fecal matter passing into the distal part prevented.

Sir WILLIAM STOKES said the more experience he had of lumbar colotomy the more highly did he think of it. Still, he did not think ill of the anterior operation. Through Mr. Croly's courtesy he had seen some of his operations, and the photographs well represented the excellent results obtained.

Dr. Fitzsimon spoke from personal observation of the invariable relief from pain and the prologation of life which followed lumbar colotomy.

Mr. KENDAL FRANKS said that, with regard to the advantage of dependent drainage in lumbar colotomy, mentioned by Sir William Stokes, he did not see why a patient operated on by the inguinal method should not be turned on his side. One of the great reasons why inguinal colotomy had met with so much favour was the greater ease with which the sigmoid flexure could be found compared with the finding of the descending colon in the lumbar operation; also, it was not always easy to know what piece of intestine presented in lumbar colotomy. The extended use of excision of the rectum, especially by the trans sacral method, was gradually turning colotomy out of the field, so that colotomy, he believed, would soon become a very exceptional procedure.

Mr. M'ARDLE agreed with the President's views with regard to lumbar colotomy. If the anterior operation was carried out fairly high up, where the bowel was readiest of access, there should be no danger.

Mr. WHEWLA, replying, said that in his opinion the anterior operation was preferable and safer, but that in some cases the lumbar operation should be done. He thought cutting the gut and returning it into the abdomen was bad surgery, as the superior end might have been sutured instead of the inferior, and symptoms of strangulation might follow from feces remaining in the distal portion, or the foreign body might ulcerate through. He had found that suturing the mesentery at the distal end kept the prolapse in abeyance. He did not think a catheter under the bowel formed as good a spur as suturing the peritoneum.

Mr. Croly said he believed the mortality was greater in inguinal than in lumbar colotomy. He thought that the lumbar colotomy should not be shirked because it was a more difficult operation.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—At a meeting on November 14th, Mr. CHARLES KING in the chair, Mr. G. MOWEN WHITE showed three cases of Fracture of Bone, showing points of interest. The first was an Ununited Fracture of the Humerus in a woman 47 years of age, in whose history no evidence of syphilis was ascertained. On account of failure to obtain union in the first instance, the ends of the bone were fastened together with ivory pegs. After a considerable period of immobilisation, union had not resulted, and the portions of ivory in the tissues had become absorbed. Then the ends of the bone were secured by short rods of nickel. As bony union still failed to occur, the ends of the fragments were exposed, and portions of fresh rabbit's bone were placed within the periosteum. Union still failed to be brought about, and the speaker said that he seemed to have arrived at the end of the justifiable methods of treatment. The President, Mr. CRAGG, and Dr. GALLOWAY discussed the case, and all concurred in the opinion that syphilis might possibly have something to do with the failure of union. Mr. WHITE also showed two cases of Fractured Patella, the one treated by means of a back splint, and approximation of the fragments by knee-caps and bandaging; the other treated by means of wiring the fragments. The superiority of the latter method was readily appreciated, both in the character of the result obtained, and in the great shortening of the period of convalescence. Dr. E. C. BRADSHAW showed a young girl of about 12 years of age, who had suffered from attacks of Gastro-enteritis. The stools showed numerous flecks of hæmorrhage, and at the same time the child had suffered from attacks of purpura. At present she was in a period of quiescence so far as the gastro-enteritis was concerned, but the purpura was still, to some extent, visible;

the skin showed numerous papules on the sites of the original purpuric spots. The speaker felt inclined to ascribe all these symptoms to poisoning by faulty ingesta, and that the enteritis was in this case an inflammation of the mucus follicles, as evidenced by the numerous minute hæmorrhages present throughout the stools.—Dr. JAMES GALLOWAY showed a patient suffering from Chronic Phthisis, who had for five years been the subject of a curious variety of Lichen Planus. The eruption, mainly on the extremities, was of the circinate variety, and in many respects resembled some of the later superficial syphilides. This patient had been treated for nearly ten months with guaiacol, in the form of the carbonate, and also as a solution of the pure product. The tuberculous had passed into a quiescent condition, and the skin eruption was better than it had been during the past five years. Cases of Embolism of the Arteria Centralis Retinae associated with Albuminuric Retinitis, and a case of almost complete Optic Atrophy following a blow on the head were also demonstrated.

LARYNGOLOGICAL SOCIETY OF LONDON.—At a meeting on November 13th, Dr. SIMON, President, in the chair, the President showed a microscopical section of a true Myxoma, which he had removed from the larynx.—Dr. J. B. BALL showed a clerk, aged 36, who had suffered from Weakness and Loss of Voice for four months. The left cord was fixed in the position of complete paralysis. He had had syphilis.—Dr. HALL mentioned a case of Complete Paralysis which had preceded signs of Aneurysm some twelve months. Dr. BROOKER suggested a central origin. The President remarked that tubes should be borne in mind, and the reflexes examined.—Mr. BOWLEY showed a lad, aged 18, with Stenosis of the Larynx following Typhoid Ulceration. The left vocal cord was fixed, notwithstanding repeated attempts to dilate the larynx, the patient could not do without the tube. Dr. SEANES SPICER, Dr. DUNDAS GRANT, Mr. O. SYMONDS, and the President joined in the discussion. Mr. BOWLEY, in reply, stated that he would lay before the lad the risk to the voice from thyrotomy, and let him decide. Mr. BOWLEY also brought forward a case for diagnosis.—Dr. A. BROOKER showed a microscopical specimen of Hæmorrhagic Myxoma of the Lingual Tonsil.—Dr. Wm. HILL showed a case in which there was a Regeneration of Tissue along the Inferior Turbinate Crest after Turbectomy.—Dr. KANTHACK showed pathological specimens of Typhoid Ulceration of the Larynx, Diffuse Papillomatous Hypertrophy of the Mucous Membrane of the Larynx, Empyema of the Maxillary Antrum.—Dr. PENNY KIDD showed a woman, aged 24, with Pachydermia of the Interarytenoid Fold. She had suffered from hoarseness for seven or eight years. Examination showed swelling of the interarytenoid fold, irregular and divided into two parts by a furrow.—Mr. BURNAN suggested tubercle and the use of the galvanocautery. Mr. O. SYMONDS thought it was tubercle, and would use the curette and lactic acid. Dr. BROOKER and Dr. TRILBY thought the only way to improve the voice was to remove a portion of the growth. The President did not look upon it as tuberculous. Dr. S. SPICER looked upon these cases as simple inflammatory thickening. Dr. KIDD, in reply, did not think the case tuberculous. He considered that these cases were localised overgrowth of tissue. Dr. KIDD also showed a specimen of Syphilitic Ulceration of Trachea with stenosis of both main bronchi.—Dr. EDWARD LAW showed a patient, aged 10, with Lupus of the Pharynx and Larynx. Examination showed much infiltration of the soft palate and pillars of the fauces, epiglottis greatly thickened, and nodular tip destroyed by ulceration. The aryepiglottic folds and ventricular bands were oedematous and swollen. The treatment would be removing the application of lactic acid, and the internal administration of arsenic. Dr. LAW also showed a case of Nasal Obstruction from septal deflection to the left side, with ridge-like projection of bone; bony enlargement of the right middle turbinate, atrophic growths, polypoid hypertrophies of the posterior extremities of the turbinates. Dr. TILLEY, Dr. GRANT, and Dr. HILL suggested the use of Jones's Turbinotomy for the removal of the turbinates.—Dr. SEANES SPICER showed a man, aged 44, with a suspicious growth on the left Vocal Cord.—Mr. W. E. H. STEWART showed a case of Malignant Disease of the upper part of the Oesophagus in

a girl aged 23. Mr. BUTLIN had recently seen a case in a girl aged 24.—Mr. STARR showed a boy with an Enlarged Thyroid, which almost blocked the lumen of the pharynx.—Dr. CLIFFORD BRALE brought forward a case for diagnosis.—Dr. DUNDAS GRANT showed a case of Disease of Wharton's Duct and Submaxillary Gland.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—At a meeting on November 21st, 1895, Mr. VACHER, President, in the chair, Dr. NEWSHOLME opened a discussion on a National System of Registration of Sickness. He observed that the value of notification of infectious diseases consisted, not in the mere tabulation of cases, but in the impulse it had given to the provision of hospitals, disinfecting stations, etc. To compare the mortality from these diseases in a town before and after the adoption of the Act, or in those in which they were and were not notified without taking all other conditions into account, was most misleading, while such short periods of observation as four years might be made to include two epidemic years in one term and none in another. Such a knowledge of the causes of a disease as was necessary for its prevention could be acquired only by notification of all cases, and there were preventable diseases other than the infectious. Of these, tuberculosis was the most important, causing a greater mortality than several of the infectious diseases put together, and its extinction was as possible as that of leprosy. Acute rheumatism, pneumonia, and others appeared from their greater prevalence in certain localities and occupations to be more or less preventable. Industrial diseases, as lead and arsenic poisoning and anthrax, should be notified to the medical officer of health, not to the chief factory inspector as required by Section 29 of the last Factory Act, and the preliminary inquiry as to whether the disease was contracted in the factory implied in the words of the clause should devolve on the medical officer of health rather than on the surgeon to the works. Compulsory notification of preventable diseases, infectious and other, had for a number of years worked successfully in Germany and Scandinavia. The Statistical Yearbook of Berlin was a mine of information, with which our Registrar-General's reports could not be compared. But in England it was impossible to obtain any extension of the system unless immediate benefits could be assured, on account of the additional expenditure, while gratuitous notification would be resisted by medical men unless they could have in exchange the legal protection from irregular practitioners enjoyed by their brethren abroad. Returns might, however, be required with little cost or trouble from all Poor-law surgeons, asylums, prisons, workhouses, schools, hospitals, etc., supported wholly or in part by imperial or local taxation or by voluntary contributions, and from friendly and benefit societies, together with the number and ages of the members or inmates. The paper was discussed by the President, Dr. WOODFORD LOVETT, Dr. YARROW, Dr. FIELD, Dr. SYKES, Dr. LAGGE, and Dr. WILLOUGHBY.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—At a meeting on November 21st, Dr. PORTER, President, in the chair, Mr. SNELL introduced a woman, aged 61, with a Malignant Tumour, probably epithelioma, involving the outer half of the left upper eyelid. It appeared to have commenced two years previously.—Dr. T. H. MORTON read notes of a doubtful case of Cancer of the Bowel. There was a slimy bloody discharge, in which spheroidal cells were revealed by microscopical examination. Dr. Morton also exhibited Bones which had been successfully amputated by his Serrated Pliers.—Dr. BURGESS showed a Tumour of the Left Optic Thalamus. There was paralysis of the right arm and right side of the knee but not of the right leg, and there was no hemianesthesia.—Dr. CLAPHAM showed a large Ulcer of the Stomach, which caused inflammation over the under surface of the liver, extending to the transverse colon, two months before death from hemorrhage. An open artery of considerable calibre was conspicuous in the base of the ulcer.—Mr. CURR demonstrated Microscopic Specimens.—Dr. KERLING gave the details of a case of Ovariectomy for the removal of a suppurating fibroid tumour of the ovary. Rapid recovery took place. The tumour appeared, from microscopical sections by Dr. Wilkinson, to be simply fibrous, with a ragged cavity at the top from which a pint and a-half of pus was

removed at the operation.—Dr. HUNT read a paper on the Treatment of Heart Disease. He related cases in which he had tried baths to strengthen the heart and reduce its velocity. He was persuaded that the use of a bath colder than the temperature of the body produced a stronger and slower pulse. The good effects of rest and certain cardiac tonics were referred to. In conclusion, Dr. Hunt drew attention to the excellent results he had obtained by the use of nitrates under conditions of high tension.—The President, Mr. PYE SMITH, Mr. ARTHUR JACKSON, Dr. SAMSON MATTHEWS, Mr. KNIGHT, Mr. MARRIOT JONES, and Mr. RICHARD FAVELL took part in the discussions.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting on November 20th, Dr. MURCH (President) in the chair, Mr. CHICKEN read a paper entitled Enterotomy and Enterectomy. He advocated making abdominal incisions as far as possible through muscular substance, as the usual incision in the linea alba left a weak scar, which conduced to ventral hernia. The first step in looking for the site of intestinal mischief should be to examine the cæcum. If no local inflammatory mischief were found the state of distension or otherwise of the cæcum was a guide as to whether the obstruction was below or above that viscus. The best method of finding the colon when the operation of colotomy was being performed was discussed, and the necessity of leaving a good "spur" insisted on. Mr. Chicken described the method of uniting divided bowel by means of Murphy's button, which was considered more satisfactory than tedious suturing. By means of Cripps's method it was possible to remove the whole rectum as high as the promontory of the sacrum. It was important to operate early in cases of cancer before the surrounding tissues were infiltrated. The treatment applicable to rectal prolapse and occlusion respectively was discussed. Dr. MICHIE thought that when pain was localised near the umbilicus or somewhat higher it indicated obstruction of the small intestine, while fixed pain elsewhere indicated obstruction of the large intestine and its seat. The amount of fluid which could be injected *per anum* would sometimes indicate the position of the obstruction. Messrs. GRAY, HUNTER, and ANDERSON also discussed the subject.—Dr. MICHIE showed a portion of Large Intestine from the Splenic Flexure, affected by Carcinoma, which he had excised from a patient who had had complete obstruction for twelve days. As a preliminary to the radical operation, an opening had been made into the ascending colon.

OXFORD MEDICAL SOCIETY.—At a meeting on November 8th, 1895, Professor THOMSON in the chair, Dr. WILSON showed a case of Progressive Muscular Atrophy in a woman, aged 30, which came on after an acute tonsillitis, and was at first thought to be of the nature of diphtheritic paralysis. The pathology of the disease was discussed.—Dr. BROOKS exhibited a female patient suffering from Anæmia, whose condition had markedly improved after treatment with bone marrow extract, iron and arsenic having previously failed.—Mr. H. P. SYMONDS showed (1) a man, aged 50, suffering from Obstruction of both Ureters. A condition of hydronephrosis existed on both sides, and had been treated by incision and drainage. The various causes of double hydronephrosis were discussed and suggestions made as to treatment. (2) A case of Epithelioma of the Penis; (3) a severe case of Rickets.—Dr. STARK read the notes of a case of Double Pneumonia and Double Empyema in a young man, aged 20, who had made a very complete recovery as the result of incision and drainage on both sides.—Dr. NELL read notes of a case of Alcoholic Neuritis with Prominent Mental Symptoms. The patient, a middle-aged widow, developed drinking habits from the medical prescription of alcohol for neuralgia. After some years insidious symptoms began to appear, which were suddenly developed in an acute form by the shock of a severe fall. There was anesthesia of the feet and hands, tenderness of certain muscles of the legs and arms, and slight muscular atrophy. There was inco-ordination of the muscles of the upper and lower limbs and of speech. There were hallucinations of all the senses, and delusional beliefs connected with the hallucinations. The memory was a wreck, and there was a good deal of emotional agitation. The supply of alcohol was cut

off. Attention was given to alimentation, small doses of liq. strychnine were ordered, and $\frac{1}{2}$ drachm of liq. morphine at night. In six months the symptoms had disappeared, except a trace of numbness in the hands and a considerable weakness of memory. This last would probably be permanent in some degree. The points of interest in the case were: the formation of drinking habits from a medical prescription, the apparently small quantity required to cause the disease, the onset of acute symptoms after a severe fall, and the predominance of mental derangement.—The following have been elected office-bearers for 1895-96: *President*: Professor Burdon Sanderson. *Vice-Presidents*: Mr. H. P. Symonds; Professor Thomson. *Secretary and Treasurer*: Dr. Collier. *Council*: Dr. Pembrey, Dr. Ritchie, Dr. Whitelocke, Dr. Neil, Dr. Turrell, Dr. Wilson.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.—The second meeting of the session was held in University College, Bristol, on November 13th, Mr. A. W. PRICHARD in the chair.—Mr. MORTON showed a patient with a Cyst of the Antrum, and a patient with Sarcoma of the Superior Maxillary Bone, undergoing treatment by injections of erysipelas toxin.—Dr. MICHELL CLARKE read a paper on Huntington's Chorea and Senile Chorea, with exhibition of a case of the former affection.—Dr. F. H. EDGEMORTH showed a series of Lantern Slides in connection with cases of Exophthalmic Goitre.

INFIRMARY MEDICAL SUPERINTENDENTS' SOCIETY.—The November meeting of this Society was held on November 16th at Lewisham Infirmary, Mr. J. R. LURN (President) in the chair.—Dr. TOOGOOD, Medical Superintendent of Lewisham Infirmary, exhibited the following cases: Ununited Fracture of Femur cured by operation, Traumatic Gangrene of Foot, Multiple Perineal Fistula cured by external urethrotomy, Symmetrical Paralysis produced by lead poisoning, Acute Conjunctivitis produced by malingering, Pelvic Sarcoma, Exophthalmic Goitre, Malignant Myopia, Tuberculous Synovitis following acute rheumatism, Malignant Tumour of Kidney, Large Calcified Fibroma of Uterus.—A vote of thanks to Dr. Toogood for his interesting series of cases concluded the proceedings.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—At a meeting of this Society on October 30th, the inaugural address for the session 1895-6 was delivered by Dr. G. VIVIAN POORE, who took as his subject the Soil in its Relation to Disease and Sanitation. The origin, constitution, and properties of the soil were fully dealt with. Some of the disease germs present in the soil were alluded to, and also its power of assimilating dead organic matter, and rendering pathogenic bacteria harmless. Conditions of drought and moisture were considered, and their relation to disease, and the evil consequences likely to result from allowing large tracts of land to go out of cultivation, were commented on.—A cordial vote of thanks was passed on the motion of Dr. HANDFORD, seconded by Dr. LAMB.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—At the first meeting of the session, held in the Faculty Hall on October 23rd, the following office-bearers were elected: *Honorary President*: Sir John Williams, Bart. (London). *President*: G. A. TURNER, M.D. *Senior Vice-President*: Malcolm Black, M.D. *Junior Vice-President*: J. Nigel Stark, M.B.; *Treasurer*: Alex. Miller, L.R.C.P.S. *Secretary*: Robert Jardine, M.D. *Reporting Secretary*: A. W. Russell, M.A., M.B. *Pathologist*: John Lindsay, M.B. *Members of Council*: Drs. J. K. Kelly, Wm. Cullen, A. R. Gunn, J. W. Jenkins, J. C. Reid, J. M. Munro Kerr.—The *PRESIDENT* made further reference to the occurrence of tetanus neonatorum in the island of St. Kilda, and reported that antiseptic precautions are now being observed in the treatment of the umbilical cord, and the two children born in the island since he read his paper last year had escaped an attack, and are still living.—Professor MURDOCH CAMERON described a successful case of Excision of the Uterus for Myomata complicated with Pregnancy, and Dr. MALCOLM BLACK showed an Anencephalic Fœtus.

REVIEWS.

THE GUIDE TO SOUTH AFRICA FOR THE USE OF TOURISTS, SPORTSMEN, INVALIDS, AND SETTLERS. Edited annually by A. SAMLER BROWN and G. GORDON BROWN. London: Sampson Low, Marston and Co. 1895. (Cr. 8vo, pp. 394. 2s. 6d.)

"GUIDE TO SOUTH AFRICA" seems an exclusive and ambitious title, but a cursory glance of this annual volume convinces the reader that almost anything which any visitor or emigrant is likely to want to know is to be found within its modest compass. It is furnished with some excellent maps of all sections of the colony. The subject of climate is fully dealt with, and it is stated on the authority of Dr. Symes Thompson that many persons occupying high positions of trust could not on account of health have fulfilled the duties had the climate been a trying one.

Bulawayo, the newest of the colonised districts affected by the English, is graphically described. It is said to be 3,800 feet above sea level. As showing the speed with which civilisation advances in the northern district, which is the centre of an enormous agricultural area, we learn that while numerous claims have been pegged out at various points, telegraphic communication is established with Charlestown, Salisbury, and other distant towns, a hospital is about to be built as a memorial to Major Wilson and those who fell with him at the Shangani River on December 4th, 1893. There is a racecourse, an athletic club, cricket and tennis grounds. The sanitary needs of the new district are not forgotten, and reservoirs and filter beds to hold about 45,000,000 gallons are being constructed a mile from the town. There will be a fall of over 100 feet, and it is proposed to use the water as a means of generating electricity.

On the all-important subject of health the *Guide* is discursive, and quotes various doctors on the advantages of a voyage to the Cape. The climates of all the different sections of South Africa are dealt with in detail, and a warning is given that Johannesburg is not, as has been supposed, a desirable resort for sufferers from pulmonary complaints, although it is generally healthy.

THE BREWING OF NON-EXCISEABLE BEERS. By J. POCOCK. Bangor: Nixon and Jarvis. 1895. (Cr. 8vo, pp. 68. 2s. 6d.)

ONE consequence of the spread of temperance principles has been a great demand for beverages as substitutes for beer, and, while ginger beer had the reputation of being innocent of alcohol, it has within recent years been promoted from the position of being the drink of schoolboys and girls to that of an article of much more general consumption. Ginger beer has also been the starting point from which the manufacture of a number of similar beverages has developed, their chief difference from ginger beer consisting in the use of hops or some other flavouring material in place of ginger. The fact that these beverages were made by a process of fermentation does not appear to have interfered with their popularity with abstainers, and it was not until the trade in them had acquired considerable proportions that the discovery was made that these supposed non-alcoholic beverages contained 3 or 4 per cent. of proof spirit, and sometimes nearly as much alcohol as ordinary Burton beer.

As beverages of that character would come within the scope of the excise law, it became necessary to fix a limit to the amount of alcohol admissible in a beverage without being chargeable with beer duty. In the manufacture of such beverages it was therefore necessary to bear this in mind and to avoid the production of too large an amount of spirit. Mr. Pocock's little book is intended to serve as a guide in this respect. It gives an easily intelligible exposition of the principles upon which the manufacture of beverages by fermentation depend, with descriptions of the nature and action of yeast and other ferments, and of the preservatives which may be employed to counteract the liability of weak alcoholic liquors to acidify or otherwise deteriorate when kept. The book bears throughout evidence that the author

has a sound practical acquaintance with brewing, and his directions are given in simple language which will make them especially acceptable and useful.

NOTES ON BOOKS.

Analytical Key to the Natural Orders of Flowering Plants. By FRANK THORNER. (London: Swan Sonnenschein and Co. 1895. Cr. 8vo, pp. 182. 2s.)—The author of this evidently carefully compiled key assumes that there is a deficiency in "exotic floras" of means for arriving at the natural order of a plant, which, as he very truly remarks, is the first stage in determining its name and affinities. Any person finding himself in this position might derive some assistance from this key; but it can only be used by a person well acquainted with the rudiments of botany, and it cannot be described as a guide to the natural orders of plants of exceptional and anomalous floral structure.

Klinische Vorlesungen über Syphilis. [Clinical Lectures on Syphilis.] Von Dr. E. von DUBINO. (Hamburg and Leipzig: Leopold Voss. 1895. Royal 8vo, pp. 386. M.6.)—This book is a German edition of a series of clinical lectures which were delivered by the author, in the French language, as Professor of Dermatology and Syphilis in the Imperial Medical School of Constantinople. The author explains that his work is not to be considered a textbook in the strict sense of the word, but whoever reads it will find that in the twenty-two lectures of which it is made up the various phenomena of syphilis as well as its treatment are clearly, and for the most part adequately, dealt with. We have no doubt the book will be highly appreciated by many others than those before whom the lectures were delivered. As the book is a German one it ought not to escape notice that there are headlines to the pages, and that it possesses both an index and a table of contents.

La Syphilis des Centres Nerveux [Syphilis of the Nervous Centres]. Par le Dr. HENRY LAMY. (Paris: G. Masson and Gauthier-Villars et Fils. Cr. 8vo, pp. 204. Fr. 2.50.)—This is one of the volumes of the biological section of the very large series bearing the title of *Encyclopédie scientifique des Aide-Mémoire*, published under the direction of M. Léauté. The book opens with some general remarks on syphilitic nervous affections, and the author then considers in detail the several ways in which the brain, its membranes, and its blood vessels are liable to be attacked. The spinal cord and its coverings are next treated in a similar manner. Then follow chapters on the cerebro-spinal complications of inherited syphilis and on etiology, the final portion of the book being devoted to treatment, on which last subject, however, Dr. Lamy has nothing new to propound. On the whole the book may be recommended as containing a clear and accurate summary of the present state of knowledge respecting syphilis of the nervous centres. But while the writings of French and German authors receive due recognition, the same remark does not apply to the work of English writers. There is no indication, for example, that the author is aware of the important work done by Hughlings Jackson in this field, and the names of Gowers and Buzzard are not even mentioned.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE
ALLIED SCIENCES.

PHARMACEUTICAL SPECIALITIES.

We have received from Messrs. F. Newbery and Sons, King Edward Street, Newgate Street, E.C., a number of samples of coated pills and other pharmaceutical preparations manufactured by W. R. Warner and Co., Philadelphia. We specially

note the elegant appearance and finish of the parvules, which are very small sugar-coated pills designed for the administration of remedies in small doses for frequent repetition. For the ready preparation of what may be called lithia water, the effervescent lithia tablets are convenient. Each tablet contains 3 grains of citrate of lithium, and when placed in water it dissolves with brisk effervescence. Inguavin is made in the form of a compressed tablet, which readily disintegrates in water. This substance is obtained from the gizzard of the domestic chicken, and is stated to possess the property of arresting certain kinds of vomiting—notably the vomiting of pregnancy. The specimens of coated pills can be commended for their excellence of finish and solubility.

THE "INDEX MEDICUS."

MR. G. S. DAVIS has just issued a list of all the subscribers to the *Index Medicus*. As the continuation of the *Index* is a matter of such vital importance to those persons who are engaged in professional literary work, it is not very creditable to British medicine and surgery to find only four copies subscribed for throughout the United Kingdom. The four subscribers are the Royal College of Surgeons of England, the British Medical Association, the Bristol Medical Library, and Mr. Young J. Pentland, of Edinburgh. There must be surely many institutions and individuals who would rather pay 25 dols. a year than be without this invaluable aid to literary work.

"THE BATTLE OF THE CLUBS."

A LOCAL SUCCESS.

WE are glad to announce that the result of the first engagement at Portsmouth has been a victory. The circumstances were fully stated last week. The medical man who held the appointment which was contested by outside men had refused to accept the new terms offered by the lodge, which were to attend infants from 3 months and juveniles of both sexes 15 years for 2s. 6d. a year. The outside competitors offered to accept 2s. 6d., 2s., and even 1s. 6d. a year, while the holder, Dr. Lord, refused to accept less than 4s. The election has resulted in the triumphant re-election of Dr. Lord, the figures being: Dr. Lord, 168; Steel, 65; Paul, 31; Todd, 11. The members of the lodge are to be congratulated on the good sense which they have thus displayed in recognising that valuable services deserve reasonable pecuniary recognition.

It is much to be regretted that the outside candidates did not take to heart the advice tendered to them, and act loyally to the profession by retiring from the contest when its true object and nature was explained to them. As it is, they have been thoroughly defeated in their attempt to undersell the profession and oust the present holder of the club office.

The Portsmouth Medical Union is to be warmly congratulated on this important victory, which will undoubtedly have a most encouraging effect on those who in many parts of the country are engaged in resisting the unreasonable and growing exactions of the clubs; it should be taken to heart by all our Branches.

At a meeting of the Folkestone Medical Society held on November 20th a paper was read by Dr. F. Easton on the Battle of the Clubs. Clubs had been organised in Folkestone by lay committees which paid their medical officer a meagre salary while they themselves absorbed the profit. The medical man was thus "sweated." Moreover the number of visits which the medical officer was required to pay during the day was too large to be compatible with careful diagnosis or efficient treatment. Dr. F. Easton read the rules of the Eastbourne and Bexhill Medical Societies, which were drawn up with a view of excluding such medical men as countenanced the above form of club. He further insisted on the necessity of a wage-limit, and of adequate yearly payment for attendance on the women and children.

An animated discussion ensued, but as the meeting was not fully representative of all sections of the Folkestone Medical Society no formal resolution was passed. The subject was adjourned till December 4th, when it is intended to take decisive action.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 429, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, NOVEMBER 30TH, 1895.

THE GENERAL MEDICAL COUNCIL.

THE fifty-ninth session of the General Medical Council was opened on Tuesday, as is customary, with an address from the President. The address began with apology and ended with eulogy. The apology took the form of an explanation of the unforeseen circumstances which prevented the new Council Chamber being ready for the meeting, and necessitated the use of the library of the Royal College of Physicians, which the College had courteously granted to the Council. The eulogy was quoted from the recent address of the Lord Chief Justice on legal education, which paid a well-deserved compliment to the Council for its efforts in improving medical education. We hardly agree with Lord Russell's description of the Council as "broadly representative in its character," and we think a closer knowledge might have resulted in a widely different expression. However, the quotation supplied the genial President with a good finish to an address, which left no doubt on the minds of his hearers as to his attitude on the question of direct representation.

After some preliminary and formal business, the resolution of the British Medical Association on this subject was reached by means of a motion, asking for the appointment of a Committee to consider the resolution and report to this session of the Council. We gathered that if such a motion had not been made, the communication of the Council of the Association would not have come before the Council at all. This was prevented by the action taken, but the result of the division was decisive, for only 7 voted for, while 21 voted against, the appointment of the Committee. In face of this resolve of the Council, the duty of the Association is clear. The expressed wish of the members, supported by the Council of the Association representing all its Branches, and speaking in the name of a majority of the profession, must be obeyed, and at its next meeting the Association Council must take steps to introduce a Bill into Parliament to increase the number of direct representatives. The other communication forwarded by the Secretary of the Association, respecting instruction in practical midwifery, was passed over on a technical objection, and then the proceedings were threatened with a collapse. This tendency is often observable on the first day of the Council's session, and is due, we think, to a want of careful preparation of the business. It is sometimes useful to have a short first sitting.

In order to set the Committees to work; but we think it a matter of regret, that the four hours on which the Council sits on each day should not be fully utilised on its own proper duties. The relations of the disciplinary powers of the medical authorities and of the Council, however, raised a short debate, and the Executive Committee were ordered to report on the subject at the next meeting. Whatever makes the discipline of the profession more effective, whether it comes through the qualifying bodies or through the Council, will be useful and popular, and we wish the Executive Committee the fullest success.

The case of Mr. Robert Masters Theobald occupied the rest of the sitting, and at its conclusion the Council decided not to restore his name to the *Register*. This is the first instance in which the Council have heard an application for a reconsideration and reversal of a decision. We are doubtful of the wisdom of the precedent thus created. It is one that must be very jealously watched. The second day's sitting was occupied with a prolonged consideration of the position of the Apothecaries' Hall of Dublin. The Council had declared the examination of the Conjoint Board of the Hall and the Royal College of Surgeons of Ireland insufficient in the subject of medicine, and had reported the same to the Privy Council. That Conjoint Board has now ceased to exist, but it seems the rights of students, who have entered for its examinations before July last, have to be protected. It will, therefore, be necessary to keep up a kind of liquidating authority to act as a Conjoint Board for some years. Moreover, before the session closes, the Apothecaries' Hall of Dublin will seek to be established as an independent examining Board by the aid of examiners nominated by the Council. Truly there seems little or no chance of ever lessening the number of portals into the profession under the present Medical Acts. In these proceedings we have the strongest arguments to encourage the Association in pressing for an amending Bill.

REVISED REGULATIONS FOR THE CONJOINT DIPLOMA.

We publish on page 1385 the text of the revised regulations of the examinations for the Conjoint Diploma of the Royal College of Physicians of London and of the Royal College of Surgeons of England. It may be a matter of surprise to some that it should have already become necessary to revise a scheme so recently issued that some of its provisions have never yet come into full operation. It has, however, for some time past been abundantly evident to those who are engaged in actual teaching work in the London schools that certain alterations were imperatively called for, unless the curriculum was to be considerably extended for most students beyond the limit of five years prescribed as sufficient by the General Medical Council. It is also noteworthy that other examining bodies, and in particular the Universities of Cambridge and London, did not follow the lead of the Conjoint Board in instituting an additional examination during the last period of the curriculum. This divergence of requirement rendered it difficult for a London student to combine the course of study for the degree of his University with that for the licence of the Conjoint Board; and what practically amounted to an additional discouragement was thus placed in the way of the student of medicine in the metropolis.

A careful consideration of the regulations as now revised convinces us that the alterations are such as tend in the direction of improving the curriculum, and of raising the standard of medical education, by leaving the schools and individual students a greater liberty of choice in the methods of clinical study without relaxing the safeguards imposed by examinational tests. The omission of elementary anatomy from the First Examination brings the conjoint curriculum almost completely into accord with the requirements of the above-named Universities, and disposes of a subject, the utility of an examination in which at this period of study has been widely doubted. Advantage has been taken of the opportunity afforded by revision to prescribe "that no candidate be rejected for a period of longer than three months, except upon the special resolution of the examiners." It seems to us that this particular regulation is open to more adverse criticism than the rest of the revisers' work. It may readily tend to increase the practice, already too prevalent amongst students, of presenting themselves before the examiners whilst ill-prepared, and of trusting to the uncertainty inseparable from examinations to obtain unmerited success. Probably the period of rejection should, as a rule, be not shorter than six months, and the briefer period of three months, though no doubt popular with a certain class of students, is less appreciated by those parents who have to pay fees for their sons' readmission to examination.

Objection has been raised to the facilities afforded by the new scheme for candidates to pass in midwifery a year earlier than in medicine and surgery. As a matter of fact, it is almost certain that the arrangements of the schools will be such as to make it convenient to the student to pass in all three final subjects at about the same date, and little advantage will probably be taken of the possibility of separating midwifery from the other great branches of professional training. General approval will, no doubt, be extended to the greater prominence given in the new regulations to the clinical part of the Final Examination.

THE SANITARY INSPECTOR AND HIS VICTIMS.

AN article in the *Building News*, on the Defects of Modern House Arrangements, deals in feeling terms with the woes of the owner of house property. It is the fault of the dry season and of the apprehension concerning sanitary defects which prevails at such a time, the writer tells us, and he is led to prognosticate the following serious results: "The machinery of the Local Government Board is set in motion, a fussy local board or vestry busies itself, and the least hint or suspicion of something wrong arouses the meddlesome action of the sanitary inspector." And then, alas, woe heaped upon woe, there is the Notification Act, which requires that the medical practitioner shall "make notification of any case of a questionable character among his patients." In any event the inevitable consequence follows. "A sanitary inspector makes his appearance on the scene; he examines the drains and their house connections, the water supply, etc. He applies the 'smoke test' to the drains, and discovers a leakage that has been going on, perhaps, for years, and forthwith condemns the whole system. Both landlord and tenant are pounced down upon with merciless severity, as if other

houses were not in an infinitely worse condition, and had been allowed to remain so for years, without any serious consequence." It might, perhaps, here be urged that a bird in the hand is worth two in the bush, and that having discovered a defect the best plan is to remedy it; moreover, the assumption that no serious consequence has resulted from infinitely worse conditions than those which obtain in a leaky drainage system is one that cannot be lightly adopted. But to return to the wrongs of the house-property owner: bad as the beginning has been, still worse remains behind. "The Public Health Act (1875) was enacted to compel property owners and others to provide sanitary dwellings, amongst other things; it was to make people sanitary who otherwise would not be. Further instalments of the law, like the Public Health (London) Act, 1891, have made it still more arbitrary and indiscriminating in its operation, so that those who have good fittings, though out of date, are treated similarly to those whose sanitary arrangements are of the worst order."

After this expression of feeling, and having dismissed the Public Health (London) Act, 1891, the article becomes more rational. We are told that the health of our houses does not entirely depend upon their drainage arrangements, and are urged to be mindful of the importance of cutting off ground air and moisture from the building, of providing a space beneath the floor boards and properly ventilating the same, and of so planning and constructing houses that the air in them may be changed continuously in summer and winter during every atmospheric condition. All this, undoubtedly, has an importance which sanitary officers are not likely to overlook, although they do insist upon the reconstruction of faulty systems of drainage. If a moral is to be drawn from the article on Defects of Modern House Arrangements, it surely is that we want an extension rather than a limitation of the present system. House-to-house inspection would ensure the remedy of the leaky drain before, instead of after, the occurrence of the case of infectious disease, and perhaps under such a system of house-to-house inspection the sanitary inspector would have an opportunity of detecting the "infinitely worse conditions" which the writer of the article in the *Building News* refers to. If the first section of the Public Health (London) Act, 1891, were fully carried into execution, and sanitary authorities made inspection of all premises in their districts, their action would at least be free from the reproach of dealing with the less evil while the greater was allowed to remain unremedied.

It is proposed by the Administrative Council of the Pasteur Institute to make an international appeal for subscriptions towards the erection of a monument to Pasteur.

We are informed that the complete report, with the statistics of the treatment by antitoxin in the hospitals of the Metropolitan Asylums Board, will be published when a period of twelve months from the introduction of the treatment in these hospitals has expired.

THE Harvelan Lectures, before the Harvelan Society of London, on the Heart in its Relation to Pregnancy, Parturition, and the Puerperal State, will be delivered by Dr. M. Handfield-Jones on the evenings of December 5th, 12th, and 19th, at 8.30 P.M., at the Stafford Rooms, Tichborne Street, Edgware Road.

A CREMATORIUM and a chapel were formally opened on Wednesday, November 27th, at Glasgow. The building, which has cost about £3,000, consists of two floors or levels, the chapel on the high level, the incinerating chamber and attendant's rooms on the basement. The Rev. Dr. Donald MacLeod dedicated the building in the presence of about 500 persons, and Sir Charles Cameron, Sir Henry Littlejohn, and other representative persons addressed the meeting.

INFLUENZA IN LONDON.

THE deaths from influenza in London showed a slight further increase last week, being 15 against 4, 7, 10, and 11 in the four preceding weeks. Of these 15 deaths 7 occurred in North London—1 in Marylebone, 2 in Hackney, and 4 in Hampstead registration districts. The remaining cases occurred singly all over London. The mortality from diseases of the respiratory organs in London showed a further decline (being 327), and were 119 below the average.

CYCLING VERSUS MORPHINE.

IN Chicago—that city of hurrying men and restless women—there were, so a popular preacher said not long ago, no fewer than 35,000 persons who habitually took hypodermic injections of morphine to save themselves from the pains and terrors of neuralgia, insomnia, nervousness, etc. Cycling has become the rage in Chicago as elsewhere, and the morphine takers have discovered that a long spin in the fresh air on a cycle induces sweet sleep better than their favourite drug. The result is said to be that the number of those in Chicago who take hypodermic injections of morphine is diminishing. Exercise and fresh air are known to all doctors to be the cure for half the ill flesh—and especially nervous overwrought city-bred flesh—is heir to.

THE POLICE AND THE PUBLIC.

IN a recent case at the South-Western Police-court, Mr. Cluer, the presiding magistrate, having inquired why a doctor was not sent for at the request of the accused, who positively denied being drunk, was told by the sergeant that the reason was because the men were unmistakably drunk. Mr. Cluer, however, pointed out that in some persons drink produces illness, and that as a doctor is called at the expense of those who wish for him, the police had no right to keep people suffering for four or five hours when a doctor might relieve them. This is not only sound common sense, but is, we believe, in full accordance with the distinct instructions issued by the Commissioner of Police on the subject, which it would be well if all subordinate officers would take care fully to obey.

DAMP HANSOMS.

THE hansom cab is perhaps the most convenient hackney carriage in the world. It is light and handy to drive, reasonably safe, and to the trained Londoner not too difficult to enter. But it has one serious drawback, of which we are reminded every returning winter. This is that the seat is very liable to get damp in wet weather. A mile or two sitting on the soaked cushions may easily result in rheumatism, sciatica, or a general chill ending in a more or less serious illness. The hansom cabman is very amenable to public opinion, and if the public generally were to take to examining the state of the cushions before engaging the cabs, it is probable that means would be found to keep them dry. Even as it is the men take a good deal of pains, but are not too well seconded by their "fares," who are very disposed to leave the doors open on getting out, whereas a moment's care will shut them. The new cabs, in which the doors can be shut by the driver, are a step in the right direction, but the difficulty of the window remains. The "fare" does not generally welcome the invitation to "have the glass down," and with a single occupant the cushions may get very wet in a short drive. Some

time ago a few cabs were to be seen in which the front was glazed in such a way that the occupant could shut the windows without running imminent risk of semi-suffocation, but for some reason or other they do not seem to have found favour either with the cab proprietors, who found them more expensive, or with the public, who in all such matters are extremely conservative. The window is the crux of the difficulty, but if public attention is called to the matter it ought not to be beyond the range of inventive ingenuity to find a remedy. Perhaps if the Society of Arts were to take the matter up and offer a prize for a really simple and practical pattern of window for hansom cabs, we might before next winter be able to drive *cito, jucunde, et—tuto*.

LIONS AND LAVENDER WATER.

A WIDELY SPREAD statement has been brought under our notice to the effect that though music has no charm for the lion and tiger, it has been discovered by a naturalist who has been conducting experiments in the Zoological Gardens that these animals are powerfully affected by the smell of lavender water; under its influence they become as docile as lambs. We have communicated with Mr. A. D. Bartlett, the superintendent of the Zoological Society's Gardens, on the subject generally, who writes us: "I am frequently amused by the funny notions and sometimes silly ideas of persons who talk and write about animals. The strange fads and mistakes they circulate are very curious; one of the fads is music, another perfumes. Now most animals have ears and nostrils, and use them, and doubtless are pleased or displeased with certain sounds or perfumes; for instance, all the cat family appear pleased with various perfumes, such as valerian, musk, lavender, and many others; it does not appear to me that there is anything very extraordinary in this. With reference to music, I live in fear that someone should state that our animals were charmed by the sound of the Jew's harp, or, worse still, the bagpipes, and that some kind friend might provide the keepers with a stock of these musical instruments to play in their leisure hours."

LEGISLATION FOR INEBRIATES: GOVERNMENT BILL.

AT a meeting of the Council of the Reformatory and Refuge Union and Prisoners' Aid Committee, held recently, Sir William Vincent, Bart., in the chair, a resolution was agreed to asking the Home Secretary to reintroduce the Inebriates Bill of the late Government, which was drawn on the recommendations of the Departmental Committees for England and Scotland, with such alterations as the present Cabinet might consider desirable.

THE HEADGEAR.

DR. BAMPTON (Ilkley) in a paper read before the local Medico-Chirurgical Society, observed that it seems probable that the most fruitful exciting cause of cold in the head is the chilling effect of the absurd headgear that men affect in a bleak winter. Where is the sense in wearing the same head covering whether the temperature is at zero or whether it is 70° F. in the shade? Nothing is more unsuitable for the purposes of warmth than a silk hat with a leather lining. We pride ourselves upon our civilisation, and yet an Esquimaux is in advance of us in the matter of winter head covering. Most of us have realised that it is folly not to keep our feet warm and dry by means of warmly-lined boots and rubber snow shoes. But few act upon the elementary principle of personal hygiene, that the head is also an extremity to be kept warm. Ladies and the working classes are not suffering so much at present for the reason, probably, that they wear something warmer than silk or felt hats. It is the professional and official classes who are at first mostly attacked, and thus become foci of infection. As men insist on clinging to their patent of respectability—the silk hat—it is to be wished that it was more generally known that a felt lining adds considerably to

the warmth of the head. By the substitution of this simple and inexpensive material for the usual leather, neuritis of rheumatic origin may be cured or prevented. It seems probable that persons who have once had influenza badly carry about with them for a long period the germs of the disease lying dormant, ready to spring into activity at the first chill taken. A similar fate befalls a patient who has lived in a malarial district. It is a recrudescence, not a fresh attack. Cold is the spark that ignites the magazine, the one element lacking to produce an explosion. How long infection lasts is uncertain; probably as long as there is cough or nasopharyngeal catarrh. Patients are loth to be convinced that disinfection is necessary, nor will they submit to prolonged isolation, nor, in fact, to any isolation at all. Yet the public call out for the medical profession to do some great thing, and will not observe the elementary precautions themselves of avoiding chill, infected persons, or infected houses.

THE EDINBURGH HOSPITAL AT LEITH.

It will be remembered that the application of the Edinburgh Local Authority to the Leith Dean of Guild Court for permission to erect a temporary hospital for infectious diseases at Quarryholes on ground under the surveillance of the Town Council of Leith was somewhat summarily hustled out of Court; also that the matter came before the Court of Session, who administered a rebuke to Leith, and ordered the Dean of Guild Court to proceed in due legal form. Not content with this, Leith petitioned the Local Government Board not to sanction the erection of such a temporary hospital as was desired by the Edinburgh Corporation. Again Leith has been snubbed. The Board has now given official sanction to the plans and also to the site proposed, and, on the suggestion of Edinburgh, has in the meantime limited the period during which the hospital may be used to three years. The buildings will be of a temporary nature, and are to be constructed at the instance of the Local Government Board in case of an outbreak of cholera or other overwhelming epidemic.

HOME OFFICE INDUSTRIAL COMMITTEES.

A few weeks ago we announced in the *BRITISH MEDICAL JOURNAL* that the Home Secretary had appointed a Committee to inquire into the effects of certain dangerous trades upon the health of people engaged in various industries. Another Committee, with a similar object in view, has recently been appointed to inquire into wool sorting, bone and hair factories, brush making, the work of furriers and tanners (employments in which anthrax occurs), stock making, leather cleaning, etc. This Committee, which is composed of Colonel Meade-King, Her Majesty's Superintending Inspector of Factories, as chairman; Dr. Whitelegge, Medical Officer of Health for West Yorkshire; Mr. Whitby, a representative of the employers; Mr. Hutton, as representing the workers; and Mr. W. A. Beaumont, Her Majesty's Inspector of Factories, Bradford, as secretary, has already commenced its sittings in Leeds. Information as to the dangers to health or to life and limb to which workers in the various industries are exposed is invited from all persons interested in this question, and should be sent to Mr. Beaumont, of Bradford, as mentioned above; or if belonging to the other Dangerous Trades Committee, to Captain Hamilton Smith, Her Majesty's Inspector of Factories, Sheffield. It may seem strange to many people that Committees of such a character should be required in an age wherein so much has been accomplished for the public health, but the fact remains that there are still several industries that lie under considerable suspicion. There is no wish on the part of the Government to be unnecessarily meddlesome, or by placing undue restrictions to prevent the full development of our industrial resources, but it is most desirable that the health of operatives should not be seriously prejudiced by the work in which they are engaged. Metallic dust and the inhalation of obnoxious

vapours in some of our factories, and the handling of skins and hair which have come to this country from foreign markets, are responsible for an increase in our death-rate. Any investigation, therefore, into the operation of these upon individual life, and any means that may be suggested as to how these dangers may be minimised, is sure to be welcomed not less by medical men than by the captains of our industries.

AN IRISH DISPENSARY DOCTOR'S DEATH.

One night last week, Dr. Kisby, of Rateragh Dispensary, Carrickmacross, was aroused from his sleep to attend a poor patient in his district. Rising from bed, he immediately set out to render what help he could. The house was about two miles away, the night was stormy and dark. He never reached the patient; and on a search being made the following morning he was found lying at the bottom of a deep pit, with his skull fractured. He was quite dead. Dr. Kisby had taken a short cut across the fields, and in the darkness had fallen into the excavation. He was greatly respected in his district, and his life was sacrificed in the discharge of duty.

THE HEALTH OF THE POPE.

Our correspondent in Rome writes: In consequence of the somewhat sudden fall in the thermometer which has taken place within the last week, the Pope was taken ill with a slight cold and hoarseness on the evening of November 22nd. The Holy Father, like most Italians, objects to any form of artificial warming of his rooms, and being of a very spare habit of body he is naturally susceptible to changes of temperature. Professor Laponi has deemed it desirable, on account of his venerable patient's hoarseness, to advise the postponement of the private Consistory which was to have been held to-day (November 25th). The Pope has for once consented to this, though he is not always a very obedient patient in this direction. No one can doubt the wisdom of Dr. Laponi's advice, as at the private Consistories—much more than at the public ones—the Holy Father has to read out the names of all the new bishops, as well as to address individually all the cardinals present. On inquiring at the Vatican this morning, I learn on the best authority that the Venerable Pontiff is much better, and that the private Consistory will be held on Friday next, and the public one on the following Monday.

CREMATION AND CRIME.

In an article on the advantages presented by cremation from a sanitary and economic point of view, and the progress that the practice is making in the several countries of Europe, the editor of *Gesundheit* offers some pertinent remarks on the forensic objections so generally urged against it as precluding the possibility of exhumation in cases where a suspicion of foul play is raised subsequent to the funeral. Murder may be, he says, by violence or by poison. The former may be recognised by the simple inspection of the body after death by any competent medical man, but no external examination can determine the mere fact of death having been caused by poison. It is only the actual presence of the poison in the body that can be used as evidence, and poisons may be either organic or inorganic. The minute quantities of the former needed to cause death, and the delicacy of the tests required, render their detection at all times difficult and uncertain. Indeed, the evidence of analysis can rarely be available for conviction unless as confirming suspicions raised by the symptoms observed during illness, when neither interment nor cremation would be permitted until the question was solved, while the instability of these substances and their liability to share in the decomposition of the corpse make it practically impossible to discover and isolate them when putrefaction has set in. We are not aware of a single instance in which this has been done as the result of an exhumation. It is different with inorganic poisons, but the symptoms of death from mineral acids and corrosive poisons

could not be overlooked during life, and arsenic, copper, and lead, as well as other metals foreign to the tissues might, if need were, be identified in the ash; but the fact is that in all countries where cremation is regularly practised special precautions are enjoined. In Italy, for example, while an ordinary certificate of death is accepted for interments, a more stringent form, having the character and under the sanctions of a sworn declaration that the medical attendant has observed the course of the illness, and has no doubt as to the diagnosis, is required for cremation. Should he feel the least hesitation in signing this a *post-mortem* examination and an analysis of the viscera have to be made by an official expert. These precautions have actually led to the discovery of accidental poisoning by copper in coloured sweets in the case of a child which had, in the first instance, been certified by the medical man to have died of enteritis or diarrhoea, and, further, to the tracing and seizure of the stock of adulterated confectionery. The real question, indeed, is whether interment without *post-mortem* examination, or cremation with the strictest pathological and toxicological inquiry, is the best calculated to secure the detection of poisoning. There can be no doubt that the existing practice of burial on the evidence of certificates by the registrar, given on the mere statement of the friends, perhaps the guilty parties, is open to grave abuse, and that if we cannot have necropsies in every case, the nature of which is not self-evident, the multiplication of these, by the extension of cremation, would tend to the prevention *per tantum* of foul play.

DIPHTHERIA IN LONDON.

THE mortality from diphtheria in London showed an increase last week, the number of deaths attributed to this disease being 69, against 72, 75, and 61 in the three preceding weeks; this number exceeded by 27 the average for the corresponding week of the ten preceding years. During the past six weeks the deaths from diphtheria in London have averaged 69. Of the 69 fatal cases recorded last week, 46 were of children under five years of age, and 21 of persons aged between five and twenty years, while only 2 were of persons aged upwards of twenty years. After distributing the deaths that occurred in the Metropolitan Asylums Hospitals and other public institutions to the sanitary areas in which the patients had previously resided, it appears that 4 cases belonged to Paddington, 5 to Kensington, 6 to St. Pancras, 9 to Poplar, 4 to Battersea, and 5 to Greenwich sanitary areas. There were 688 cases of diphtheria under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital, on Saturday last, and 103 new cases were admitted during the week.

A HEAD CASE.

ONE of those cases which so often bring trouble to house-surgeons occurred at Dublin the other day. A man, who had taken some drink, fell down the stairs of a music hall, and was conveyed to Jervis Street Hospital by a policeman. The house-surgeon made an examination, could find no injury, and declared the man to be under the influence of drink; and he was accordingly taken to the police station. Here he was locked up in a cell. He was noisy, challenged a fellow prisoner to fight, and generally was quite a lively person for some hours. Then he became quiet, and later on the police noticed that he was breathing heavily and was quite unconscious. He was at once conveyed to Mercer's Hospital, but he was there found to be dead. The *post-mortem* examination showed a large extravasation of blood on the brain, and generally diseased organs. The coroner's jury declared that no one was to blame. We refer to the case to accentuate the importance of its lesson to young resident medical officers. They have to bear great responsibility, and the reputation of the hospital is in their hands. Of course it would be impossible to turn a ward into a place

for receiving all drunken persons who had met with some apparently trifling accident. But cases of this kind, in which the patients are probably suffering from chronic alcoholism as well, ought to be examined with the most scrupulous care, and generally regarded with some suspicion. With diseased organs and diseased arteries these people are particularly likely to suffer much from slight violence, and it is always better to give a bed to a case of alcoholism, and to have the diagnosis verified in the morning, than to send it away quickly to discover that death has decided all doubts. Cases of this kind ought to have the effect of inducing the governors of all general hospitals to provide a special ward for the reception of doubtful cases of injury in which alcoholic symptoms are prominent. So long as this precaution is neglected, the governing bodies must bear the major part of the blame of such unfortunate occurrences as that here related.

THE HUXLEY MEMORIAL.

THE first meeting of the General Committee formed for the purpose of establishing some memorial to the late Professor Huxley took place on November 27th at the Museum of Practical Geology, Jermyn Street. The Duke of Devonshire presided, and, in opening the proceedings, sketched the official connection of Professor Huxley with the Science and Art Department, and described the great public services he had rendered in that connection. Lord Kelvin, in moving that it was desirable to establish a memorial to the late Right Hon. T. H. Huxley, dwelt on the late Professor's devotion to the work of original investigation and his achievements in comparative anatomy, biology, geology, and palaeontology. Mr. Arthur Balfour, who seconded the resolution, said Professor Huxley, as a man of letters and a man of science, surely deserved from his fellow countrymen some permanent memorial. In the critical period of scientific history which followed the publication of *The Origin of Species* he did more than any other man to stimulate public interest in the subject and to bring into line all the younger scientific thinkers of the day. Lord Playfair supported the resolution, which was unanimously carried. Sir Joseph Hooker moved a resolution that the memorial take the form of a statue, to be placed in the Museum of Natural History, and a medal in connection of the Royal College of Science, the surplus to be devoted to the furtherance of biological science. Mr. Leslie Stephen seconded the resolution, which was carried, and an Executive Committee was appointed.

THE MISSING LINK.

ON November 22nd, Dr. Dubois from Holland delivered an address on "*Pithecanthropus Erectus: a Transitional Form between Man and the Apes.*" in the new buildings of the University of Edinburgh. Professor Sir William Turner, on whose invitation Dr. Dubois came to Edinburgh, presided, and introduced the lecturer. By order of the Dutch Indian Government Dr. Dubois conducted from 1890 to 1895 explorations in Java for a fossil vertebrate fauna, of which some remains had already been discovered many years ago by various investigators. These vertebrate remains, which were found abundantly at Trimil, on the southern slope of a range of low hills, the Kenjungs, were contained in beds of cemented volcanic tuff, consisting of clay, sand, and lapillistone, of fluvial origin. The whole formation of the strata reached a maximum thickness of 500 metres, cut up to a depth of 12 to 15 metres by the channel of the river Solo. The strata in question rest on beds of marine marl, sand, and limestone, and are of the Pliocene age, as Professor Martin has determined. In August, 1891, Dr. Dubois, working in these strata, came upon a large number of fossil remains of various vertebrate types, and among them the bones and teeth of a great ape-like mammal, to which he had given the name of "*Pithecanthropus Erectus*," because he considered it a link of con-

nection between man and the ape. A year ago he published a provisional description of these remains, and the criticisms since then had shown much divergence of opinion. Only in regard to the femur was there anything approaching unanimity of opinion, and it is regarded as human. Virchow alone has suggested that it might have belonged to an ape. For normal human proportions the cranial capacity was too small for the femur; but microcephalic skulls of the atavistic class can be relatively smaller, while the height of the body is more than that of *Pithecanthropus*, as computed from the length of the femur. The skullcap had given rise to very great divergence of opinion, some taking it to be that of an ape, others, including Professor Cunningham, regarding it as undoubtedly human. Dr. Dubois entered into details of measurement, etc., that seemed to prove that the skull was more human than ape. He then referred to the molar tooth in some detail. All the facts and circumstances seem to Dr. Dubois to afford evidence of a form intermediate between man and the anthropoid apes. He believed the form to be a transitional one, and in the direct genealogy of man. Some discussion followed, in which Professor Cossar Ewart, Sir William Turner, and others took part. Dr. Dubois delivered an address on the same subject to the Anthropological Society in London on November 26th.

THE ROYAL PHYSICAL SOCIETY OF EDINBURGH.

At the first meeting of this Society, held on November 20th, Emeritus Professor Struthers, M.D., LL.D., in the chair, Dr. William Russell, the retiring President, delivered the opening address, his subject being the Light Thrown on some Biological Processes by the Investigation of Disease. He discussed the functions of the ductless glands as illustrated by the thyroid, whose functions had been discovered as a result of diseased conditions. Cretinism and myxodema and their relation to the thyroid and to blood serum were referred to. He discussed the nature of immunity and some of the methods by which it was attained. This immunity appeared to enter into every tissue, and might even be transmitted. The whole subject was full of endless ramifications and possibilities, many of which could not yet be discussed scientifically.

CHOLERA IN ST. PETERSBURG.

Our St. Petersburg Correspondent writes: It is officially announced that cases resembling cholera began to appear in St. Petersburg as long ago as October 10th (22nd). Between the 10th (22nd) and 26th (November 6th) there occurred in all 27 such cases, 12 of which ended fatally. The daily bulletins, which had become so familiar during the last three years, are again being published in the papers by the municipal authorities. In these the cases are still described as "resembling cholera," but I am informed that in some, at least, the cholera bacillus has been found. Between October 26th (November 7th) and October 31st (November 12th), both days inclusive, 21 cases were reported, with 12 deaths, and between November 1st (November 13th) and November 9th (November 21st), both inclusive, 43 cases were reported, with 21 deaths. There have, therefore, been altogether 91 cases, with 45 deaths; and at the present moment 28 cases remain under treatment.

SIR WILLIAM MACGREGOR, M.D., K.C.M.G.

SIR WILLIAM MACGREGOR, Lieutenant-Governor of New Guinea, who recently had a narrow escape of being murdered while paying a visit to a friendly tribe, is a member of the medical profession. He took the degree of M.B. in the University of Aberdeen in 1872, and that of M.D. in 1874. He was appointed chief medical officer of Fiji, afterwards becoming Deputy Administrator of that colony, and some years later Lieutenant-Governor of British New Guinea, where he has earned a very high reputation as an able and successful administrator. The example of Sir William

MacGregor, taken in conjunction with those of Sir George Robertson, Sir John Kirk, Sir Rutherford Alcock, and Dr. L. S. Jameson of Mashonaland, would seem to prove that a medical training is one of the best possible preparations for the government of new countries, particularly when natives have to be conciliated. Scientific medicine is the most powerful of all civilising agencies, and the knowledge of human nature which the study of it gives, together with the living conviction which it engenders that the foundation of good government is to keep the people healthy, help to make a medical man who is otherwise qualified to be a leader of men the best possible ruler of countries in the transition state from barbarism to civilisation.

CONVOCATION AND THE NEW UNIVERSITY FOR LONDON SCHEME.

A MEETING of members of Convocation of the University of London was held on November 25th to consider what steps should be taken in view of the effort which is being made to secure the support of the Government for Lord Playfair's Bill, which is intended to give effect to the report of Lord Cowper's Commission, and override the existing rights of Convocation. In the discussion which took place it was stated that at a deputation to the Duke of Devonshire and Lord Salisbury, on June 13th last, the suggestion was made that should the Bill be introduced in the Lords an amending clause should be proposed which would insist on the scheme, when arranged, being submitted to Convocation for approval in the manner prescribed for senatorial elections. It was understood that the Duke of Devonshire and Lord Salisbury approved of such a clause. Sir John Lubbock has similarly pledged himself in his electoral address of July 1st of this year, that unless such clause were inserted he would oppose the Bill in the House of Commons. Those present felt they had a right to assume that under these circumstances the Unionist Government would not be likely to support the Bill without alteration.

MATERNAL SUCKLING.

THE Tsaritsa is to be congratulated upon having both the determination and the ability to dispense with the services of wet nurses, and to undertake herself the duty of nourishing her infant daughter. It is said that she is the first Empress of Russia who has ever done so. Fashion is responsible for so much in all that pertains to woman that this event may possibly be life-saving to many infants yet unborn. It no doubt is true that the habits of modern life do unfit a certain number of women for the proper fulfilment of their maternal duties, but there is much reason to believe that the neglect of their infants, which is so common nowadays, is far more often due to fashion than to any real inability to afford them a proper supply of nourishment, and anything which will set the fashion in the direction of more natural methods in the rearing of infants will be of much service in checking the spread of many forms of infantile degeneration.

THE SECRET OF CENTENARIANISM.

A "CHIEF" from *Tit-Bits* has been with Sir Benjamin Ward Richardson, "takin' notes" of his opinions on things in general, which he has printed for the edification of the readers of that educational periodical. The eminent physician fought all his scientific battles o'er again, and confided to his appreciative listener many interesting details as to his professional career. With these we have no concern at present. On one point, however, as to which the interviewer was particularly eager to hear the deliverance of the oracle, the reader will doubtless to some extent share his curiosity. Sir Benjamin gave it as his "fixed opinion that every man, and every woman for that matter, should attain the age of 100." He proceeded to show how this was to be

done. First of all, as we gather, the would-be centenarian must have "light hazel eyes, light brown hair, complexion inclined to be florid, lips and eyelids of a good natural red—never pale, and rarely of a bluish tint." Then he must never smoke and never drink—the prohibition is absolute, but we presume the restriction applies only to alcoholic liquors; further, he should eat very little meat. He should work as little as possible by artificial light; in fact, one of Sir Benjamin's most widely quoted sayings, we are told, is: "Make the sun your fellow workman." If, by the way, this rule is strictly adhered to in this country, few people are likely to die of overwork. What the colour of the eye may have to do with longevity does not seem to have been revealed to the interviewer. An American authority professes to be able to diagnose a predisposition to centenarianism by the length and breadth of the head; he says nothing as to its thickness, which yet may help to make a man's days long in the land. As to the rigid abstinence from tobacco and alcohol enjoined by Sir Benjamin Ward Richardson on all candidates for the long distance race of life, it has almost as slight a basis of fact as the importance he attaches to the colour of the eyes. Immoderate drinking of whisky, like immoderate drinking of tea, or for that matter immoderate eating of bread, will shorten life; but what evidence is available on the subject seems to show that a strictly temperate use of alcohol tends to prolong life, for the excellent reason that it assists digestion, and thereby promotes health. The most trustworthy statistics on this subject are those of Sir George Humphry. Of 45 cases of centenarians collected by him only 12 were total abstainers, while 30 were moderate drinkers, and 3 were heavy drinkers. Of 889 persons between 80 and 100 years of age in Sir George Humphry's tables only a fraction over 12 per cent. were abstainers, while nearly 9 per cent. were heavy drinkers. The abstainers would appear from these figures to have only a slight advantage in point of longevity over the non-abstainers. The real secret of centenarianism is well expressed by Sir George Humphry when he says: "The prime requisite is the faculty of age in the blood by inheritance." In other words, if you wish to live a hundred years you must, as Oliver Wendell Holmes said of another matter, begin by going back two or three hundred years, and securing for yourself a sound and long-lived ancestry.

THE SALVATION ARMY SHELTER.

On November 21st the hearing of the summons against the "captain" of this shelter for overcrowding was again resumed at the Southwark Police Court, and the case was concluded. It was contended by the prosecution that the cubical air space of the shelter was only sufficient for the accommodation of 400 persons, while on the other hand witnesses were called for the defence who stated that 800 or even more persons could be accommodated without injury to health. One of these witnesses, who stated that the building would fairly accommodate more than 800 persons, observed that 123 square feet of floor space and a cubic space of 160 feet was sufficient in that place, but would not be sufficient everywhere. This witness added that if the London County Council required 36 square feet and 300 cubic feet in common lodging-houses no doubt there was good reason for it, but in this shelter less was sufficient because of the great attention which was paid to cleanliness and ventilation. The magistrate, Mr. Stide, said he was satisfied the shelter had been overcrowded, the lowest of the numbers admitted during July and up to August 5th, when the summons was issued, being 743, a number which would overcrowd the shelter so as to be injurious to health. In order to save time and expense Mr. Stide added that personally he would not be prepared to convict for overcrowding at this shelter if the number of 500 were not exceeded; an order would be made to prohibit the recurrence of the nuisance, with 4s.

costs. The magistrate's decision is an important one, and although he was dealing only with a particular case, his standard will no doubt be quoted in the future in connection with the fixing of a limit to the degree of crowding which is to be permitted in other instances. The standard does not seem to be a high one, but it is a great gain to have reduced the crowding to the extent implied by the magistrate's decision. The Vestry of St. George the Martyr and their medical officer of health, Dr. Waldo, have done good service in calling attention to the condition of the shelter, and in showing the need of regulating the extent of crowding which is to be permitted in such places.

AN IMPORTANT DECISION.

It will be remembered that a case was heard in Dublin some months ago in which an action was taken against Dr. David Hadden for having improperly declared that an employee of the plaintiff Mason was suffering from small-pox, when she was not so suffering from that disease. The plaintiff obtained £100 damages, and the defendant on November 26th applied to the Court of Exchequer to set aside the verdict on the grounds of misdirection and of non-direction by Mr. Justice Murphy, who heard the case, in refusing to direct a verdict for defendant, and because no evidence was given of negligence or want of skill on the part of the defendant proper to be submitted to the jury. The Lord Chief Baron, in delivering judgment, said that there was nothing in the entire case to be found which could legitimately have been left to the jury as evidence to displace the affirmative evidence of Dr. Day, that at the time he saw the patient small-pox might reasonably be diagnosed. It followed that there was no evidence to support the plaintiff's case. The verdict must be changed, and there must be judgment for the defendant with costs. Mr. Justice Anderson concurred.

SEA WATER FOR LONDON.

THE next session of Parliament will, we are informed, have before it a scheme for providing a supply of sea water for London and certain places on the route. The intention is to take in the water from the sea opposite Lancing, where all the pumping machinery will be situated. It will be pumped thence to a large reservoir in an elevated position at Steyning, whence it will flow by gravitation to another reservoir at Epsom. From this reservoir it will be distributed over London, the parts to be first supplied being the West-end and central portions. It is stated that local authorities will be supplied with sea water for flushing sewers, watering streets, and other public uses, such as swimming baths, and that sea water baths will be supplied to hotels, hospitals, schools, etc. We hardly need point out that the success of such a scheme is likely to depend on the price at which the sea water can be supplied. As to any relief to present sources of water supply by using sea water for public purposes, it should be mentioned that the quantity proposed to be provided is stated to be only 10,000,000 gallons per day, while the average daily supply of water to London amounted in 1893 to over 100,000,000 gallons.

MEDICAL CERTIFICATES AND THE SCHOOL BOARD.

MR. SHARP, the Chairman of the School Accommodation and Attendance Committee of the London School Board, has published a letter in explanation of the action of the School Board in appointing medical officers to supervise the medical certificates, or, in the words of the resolution of the Board, "to examine cases in which the medical certificate produced is considered by the divisional superintendent to be doubtful." The matter has a far wider bearing than Mr. Sharp seems to imagine. It involves first the great question in medical ethics as to the propriety of any medical man visiting, investigating, and reporting upon a patient who may be under the care of another doctor. In regard to this side

of the question we cannot expect Mr. Sharp to have any sympathy, or indeed, any knowledge; he will probably dismiss it as a matter of "medical etiquette"; but, nevertheless, it is certain that the feeling in the profession is so strong on the point that few will ever be likely to undertake so thankless an office. But besides this there arises the whole question, Why should medical men go to the trouble and undertake the responsibility of giving these certificates if they are not to be accepted as excusing the children from attendance at school? If the medical certificate is not to save the parent from further trouble, there seems no reason for giving it. The resolution of the Board "That the names of the doctors selected shall be forwarded to the magistrates having jurisdiction in the division" seems to be extremely ill judged. The obvious intention of this resolution is to suggest to the magistrate that the evidence of these gentlemen is to be accepted with some special consideration. It is to be hoped that most magistrates will recognise that the evidence of official witnesses must be carefully scrutinised.

FREE DISINFECTION.

WITHOUT underrating the value and necessity of a Government audit of the accounts of local sanitary authorities, it is possible to entertain much doubt as to the value of the criticism upon items of sanitary expenditure in which some auditors are in the habit of indulging. As an instance in point, Dr. Barwise, in his annual report as county health officer for Derbyshire, calls attention to the objections raised by the auditor in more than one district to the outlay incurred by the gratuitous distribution of disinfectants to infected households. This is surely a matter of which the local authorities, under the advice of their medical officer of health, and not the auditor, are the best judges. His objection can only mean that the disinfectants should be of a cheaper kind, or distributed in less quantity, or to fewer households, or not at all. Dr. Barwise supplies several excellent and obvious reasons for leaving these questions to the discretion of the proper authorities, and for encouraging, rather than hampering, their efforts in the direction of disinfection. The object of giving the disinfectants, he says, is to protect the public rather than the household, and the ratepayers, if so disposed, may reasonably claim to be allowed to take care of their own safety at their own cost. If the matter is left to the householder, his choice may fall upon useless disinfectants, or no disinfectants at all. If it be said that the free supply should be limited to the very poor, there is no machinery, no officer whose duty it is to make the financial inquiries upon which this invidious distinction could be based. This is plain common sense, with an application to other details than those of disinfection, and we hope that the one department of the Local Government Board to which the country looks for light and guidance in the prevention of infectious diseases will take note of it.

A LINK BETWEEN HOSPITAL AND PRIVATE PRACTICE.

AN inquiry has been instituted by the secretary of a special hospital in London as to the practice current at other hospitals in regard to supplying the names and addresses of members of the medical staff to applicants desirous of privately consulting one or other of them. Information was received from 25 institutions; at 79 of these, including Charing Cross, University College, St. George's, London, King's College, Guy's, and Middlesex, in London, the custom seems to be to furnish a complete list of the staff in their order of seniority. The St. John's Hospital for Skin Diseases not only does this, but adds in red ink the time at which the members of the staff state that they attend at their private residences. At the other 15 institutions various plans are adopted; 6 of these merely refer the applicants to the *Directory*, a plan which of all others seems to be the

simplest and least compromising. Doubtless at some of the special hospitals this method of notoriety, *à la* the hall porter, may be productive of guineas, and just to that extent is to be reprobated, but we should imagine that at the large general hospitals such a mode of introduction is extremely uncommon. In any case we would appeal to the members of the staff of the great hospitals, who have doubtless not given thought to the matter, to take care that such a system of introduction is put an end to. It will be obvious that the publication of the results of this inquiry by a particular special hospital can only have been for the purpose of showing that the proceedings there current were somewhat similar to those in operation at other and much more important institutions, and of thus obtaining some countenance for its own doings. It seems to us a degrading thing that any member of the staff of a great hospital should be driven by the custom of the place so to place himself in the hands of the porter; it is a plan which is open to very serious objection on the part of the general practitioner; and on the very lowest ground, especially seeing how the example is being exploited, it may fairly be suggested that *le jeu ne vaut pas la chandelle*.

THE PORTSMOUTH MEDICAL UNION AND THE CLUBS.

WE are glad that a complete victory has been gained by the Portsmouth Medical Union, and that Dr. Frederick Lord, who has held the post of lodge surgeon for the last twenty years, has been re-elected by a very large majority. It must be a matter of satisfaction to him that he has received the united and cordial support of the medical practitioners residing in this large centre, and it clearly indicates the esteem in which he is held by his professional brethren. We desire heartily to congratulate all who have taken part in the battle, which has been fought and won by united and honourable effort. Practitioners holding lodge appointments are frequently exposed to similar unjust treatment, involving a reduction of salary in combination with increase of professional duty, and surely this triumph at Portsmouth ought to stimulate them to defend themselves, and to stand firmly shoulder to shoulder in the hour of trial. Many devices for developing new systems of medical defence have lately been freely discussed, but in conflicts of this kind it would be useless to appeal for help to any central organisation. Practitioners in every locality must look to themselves to develop an efficient system of united action, ready to cope with all such emergencies. The Branches of our great Association scattered throughout the country should form the Medical Unions of the future, and become the instruments for sustaining the rights as well as the honour of the medical profession.

SANITATION IN JAPAN.

DR. ELDRIDGE states that during the late epidemic there were 1,382 cases of cholera in Japan itself, representing, probably, the invasion of at least a hundred different localities, and yet, with the exception of certain of the military ports at which the imported cases were first received and where it has been most successfully handled and restricted, the disease has in every instance been stamped out with the occurrence of the first half dozen cases. Considering that thousands of troops and coolies are now returning to their homes the work accomplished this year by the Japanese in controlling and limiting the spread of cholera is not only marvellous but, he thinks, unprecedented. Until within a few years the introduction of even a single case of cholera practically ensured a widespread epidemic. The sanitary system of Japan dates from 1877 only, and its officers have had to be educated and trained *ab initio*. As a matter of fact the Government has had so far during the present emergency no advice or assistance whatever from foreign experts.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

WINTER SESSION, 1895.

Tuesday, November 26th.

Sir RICHARD QUAIN, Bart., in the Chair.

THE Winter Session of the General Medical Council took place at the Royal College of Physicians. This is the fifty-ninth session of this Council.

THE PRESIDENT'S ADDRESS.

THE PRESIDENT opened the proceedings with the following address:

GENTLEMEN.—In formally opening this, the fifty-ninth session of our Council, I have to express great regret and disappointment that the Council has been prevented from meeting in its own chamber, and that it may thereby be put to inconvenience. We are, however, very much indebted to the Royal College of Physicians of London for the readiness and courtesy with which they have afforded us the use of their library, as they have done on many previous occasions. I am desirous of fully informing the Council as to the difficulties with which we have been met. The freehold of our premises had been purchased, the designs for the new building had been approved of; Mr. Porter, the architect, had entered into negotiations with the owners of the adjoining premises for the purpose of arranging as to the contemplated alterations in the building, and, as far as was known, with satisfactory results. The contract having been signed, the building proceedings had progressed, the chief surveyor of the Office of Works had inspected the premises, and stated his readiness to report that the building would not interfere with their tenant of 16, Hanover Square. It was found, however, on a copy of the sub-lease to Mr. Rogers, the tenant of the house in Hanover Square, being forwarded them from the Office of Works, that besides the usual conditions safeguarding the rights and privileges of Mr. Rogers, there was an exceptional clause in this sub-lease which provided that the Office of Works must not "increase or permit to be increased the height of the building situate at the rear of the messuage and tenement and premises hereby demised and now occupied by the Council of Medical Education without the consent in writing of the said Joseph Rogers." Under this clause Mr. Rogers made certain representations to the Office of Works as to the increased height of the building, whereupon on September 18th, 1895, the secretary of the Office of Works communicated to me, for the information of the Council, that "in these circumstances the Board's solicitor advises them that they are not in a position to consent to the proposed alterations unless the Council can come to some arrangement with Mr. Rogers." Placed in this position, a communication was opened with Mr. Rogers and his representative, who made a most unreasonable pecuniary claim for so-called compensation, a demand which could not possibly be acceded to. Much time, involving great anxiety, has been devoted to the subject, with the result of preventing the continuance of the building, and its arriving, as it would otherwise have done, at completion long ere this. As a result, however, of the negotiations the plans have now been modified, and have been so far approved by the First Commissioner of Works, but these modified plans would leave the Council Room roof at a lower elevation than would be architecturally acceptable, and would leave the arrangements for the accommodation of strangers inconvenient. When finished, however, as we anticipate our chamber will shortly be, the members of the Council will, I hope, have every reason to be satisfied with the accommodation which we shall be able to provide for them. They will find that the warming and ventilation have been carefully attended to, and that the drainage, which was found to be most defective, has been effectually remedied. This has been done by connecting the house drain with the main sewer in Oxford Street at a depth of 58 feet. The Council is greatly indebted to

Dr. Thorne Thorne and Mr. Teale, our fellow members, for the trouble they have taken in reference to these particular subjects. Having thus informed the Council as to the subject of the building, I do not propose to occupy your time by any lengthened observations, for I entirely agree with an opinion expressed to me by several members of the Council that the present session should be devoted to the consideration only of matters of pressing necessity, and that other business, important but less urgent, might be postponed to the May session. The report of the Examination Committee on the Reports of the Visitor and Inspector on the Final Examinations considered as a whole, together with the recommendations of the Committee, is ready, and may be considered now or postponed, as the Council may think fit. A report is being prepared by the Public Health Committee on the examinations in that subject by some of the bodies, but there still remain two to be inspected. A report will also be presented on one out of the four examinations for licences in dentistry, but the Dental Education and Examination Committee will postpone their report thereon till the inspection of the other bodies is completed. I have pleasure in informing the Council that considerable progress has been made in the preparation of the new edition of the *British Pharmacopæia*. The members of the Pharmacopæia Committee met on three days in July—24th, 25th, and 26th—and on two during the current month—22nd and 23rd. The several valuable suggestions made by the medical authorities in this country have been carefully considered, including points of construction in the *Pharmacopæia*, alterations in the various classes of preparations, as well as in many individual preparations. The whole of the large number of suggested additions and omissions have been considered. The suggestions of the Indian and other colonial authorities have also, so far as possible at present, been dealt with. A committee of the Pharmaceutical Society has aided, and is aiding, the Council in the production of the work. The Editor reports satisfactory progress in all its sections, some portions of the work having been already set in type, printed, and placed before the Pharmacopæia Committee. The co-operation of referees, as stated in the report of the Committee in June last, has been invited and cordially rendered. In Pharmacology, Dr. Lauder Brunton, Professor Fraser, and Dr. Walter Smith are prepared to render their assistance; in chemistry, Dr. Thorpe, with Professors Tilden and Emerson Reynolds; in botany, Mr. Thielton-Dyer and Mr. Holmes. We may thus anticipate that though the period for the production of the *Pharmacopæia* may be somewhat postponed, the delay will be compensated for by satisfactory results. I have caused to be printed, for the convenience of the Council, in a separate form important documents in connection with the Conjoint Board of the Royal College of Surgeons and the Apothecaries' Hall of Ireland, which include the representation made by the Council to the Privy Council on the subject of deficiencies in the examinations of this Board, together with the observations on the subject addressed to the Privy Council by the College and the Hall; also a letter from the Lord President of the Council, in which his Grace points out that, the Conjoint Board having ceased to exist, it was unnecessary to take further action in the matter. A further communication to the Privy Council, from the Secretary of the late Board, has indicated the apparent necessity for a continuation of the proceedings of the Board for the examination of candidates who might, by their previous arrangements, have a claim to be examined. The opinion of the legal advisers of the Council will be submitted, together with the documents. It will be seen also that the Apothecaries' Hall of Ireland, regarding the Conjoint Board as having ceased to exist, makes an application to the Council for the appointment of assistant examiners in surgery in accordance with the provisions of Clauses 3 to 5 of the Medical Act (1886). In reference to the subject of penal cases, which happily on this occasion are but few—indeed, there would seem to be but one case which can be brought before the Council during the present session—I may mention that there has been, in the opinion of the Penal Cases Committee and the solicitor, no well established case of "covering," of which there have usually been several, and I trust I am not premature in congratulating the Council on its action, by which there is every prospect that this

obnoxious system is being steadily put an end to. There are two cases of practitioners on whom, in accordance with the option provided by the Standing Orders, the Council did not, on hearing their cases in November, 1894, and May, 1895, respectively, proceed to pass judgment, thus affording them an opportunity of satisfying the Council that the conduct complained of had been discontinued, and of this they submit evidence to the Council. The Council should be informed that the Solicitor has prosecuted Mr. Allinson for the continued use of a medical title of which he had been deprived. The case was heard by the magistrate at the Marylebone Police Court on June 26th, 1895, and Mr. Allinson was fined £20 and £10 10s. costs, or in default of distress a month's imprisonment. His counsel asked for a "case," which was granted by the magistrate; but I am informed that the defence has not accepted the "case" as stated, and will not proceed further in the matter. The prosecution of a similar case in Leeds has been postponed until the final decision in the case of Mr. Allinson. It will now be proceeded with. The consent of the Council will be asked for the prosecution of a person to whom the Council's attention is drawn by the Royal College of Physicians of London. The case is one in which an individual, not being registered, assumes a professional title, is engaged in the treatment of diseases, and circulates indecent publications. Communications, which will be found in the programme of business, have been addressed to the Council on matters in which the constitution and functions of the Council are concerned. It seems to me that, in my capacity as President, it is my duty to notice, however briefly, some of the suggestions which not for the first time have been made in regard to these subjects. For instance, it is suggested that an increased number of direct representatives of the medical profession should be elected on the Council, and that certain functions, in which such direct representatives would have a special interest, might then be assigned to, or undertaken by, the Council. With reference to the functions of the Council, we must remark that this Council is the creation of the Crown, acting on the advice and with the consent of both Houses of Parliament, as expressed in the Medical Acts, and created primarily in the interests of the public to secure for that public competent professional aid. As I have just said, the protection of the interests of the public is the first duty assigned to the Council, as instanced by the means taken to secure the efficient education and competent skill of the members of the medical profession. This is accomplished by improvements in the course of study and in the prolonged curriculum. It is not possible, nor is it necessary here, to enter into details as to the methods by which this has been effected. Much has been already done, and it is thus, by further improving the standard of education and exercising the powers which the Council possesses of removing unworthy members from the ranks of the profession, that our status will be elevated and the real interests of our members secured. The Council has had assigned to it the duty of forming an accurate Register of competent practitioners; and to keep that Register free from all unworthy elements. The Council has also the duty of preparing and publishing the *British Pharmacopœia*. There are many very estimable persons who would call on the Council to undertake other duties, such, for example, as taking cognisance of matters of professional etiquette and improper conduct and action, whether in the relations of the profession to the public or among members of the profession itself, and without question, many of these grievances may be deserving of investigation and censure. The duty of investigating the subjects to which I refer should come under the notice of the licensing authorities which have conferred the licence to practise on the individual complained of. Several of these bodies can and do exercise these controlling powers, and what some do all should be induced to do. By this action on the part of the medical authorities, by putting in force their by-laws and regulations, many of the grievances which our profession justly complain of might be remedied. The duties of the Council are of a far higher and a more important character, which promise every year to become of yet greater public importance, and I am satisfied that were the Council to interfere in these matters of ethical detail it would but lose its authoritative influence with the Government and would give only doubtful satisfaction to the public. In reference to the constitution of the Council argument in

favour of the election of additional direct representatives is deduced from the practice of, amongst other bodies, the Incorporated Law Society. Now, it must be observed that this Society, which is very similar in its constitution to the British Medical Association, though chartered, is a purely voluntary association, comprising amongst its members only a portion of the qualified practising solicitors. They each subscribe 1 guinea per annum. This body can and does institute inquiries into the conduct of members of the profession against whom complaint has been made by any member of the public. If the Council of the Society is satisfied that a case is made out, they appear in support of it before a Common Law judge, who gives a decision upon it. This system contrasts very much in favour of our Council, which is itself empowered to investigate charges made against delinquent members of the profession, and itself to pass upon them a judgment from which there is no appeal. It is said in favour of the election of additional direct representatives, that the medical practitioners, who contribute by their registration fees to maintain the Council, should have a larger share in its constitution. Again, a comparison may be made with the profession of solicitors. Solicitors pay large apprenticeship fees, and they have to render prolonged unpaid service to the solicitors to whom they are articled, they pay fees for education and examination, and, before being admitted to practise, they are required to pay stamp duties to the Inland Revenue authorities amounting to £110. They also pay annual fees for a licence to practise in London of 3 guineas each, and for the privilege of practising in the country of 6 guineas each. Observe, that over the expenditure of these contributions they have no control whatever. The facts just mentioned clearly indicate that members of the medical profession, who pay only one inclusive fee for life of £5 for technical admission to the *Medical Register*, should not be discontented with their position as compared with that of the legal profession, so far as the payment of fees and the control of the expenditure are concerned. According to my experience, an increase in the number of members of the Council, which is not a legislative but a deliberative and administrative body, would only tend to embarrass and delay its proceedings. The members of the Council are elected and appointed under the most varied representative conditions, but they all tend to secure the high character and ability of its members with a result which cannot be denied. Before concluding these observations I am tempted to quote from a recent address by the Lord Chief Justice of England on the subject of the improvement of legal education—an observation which has special reference to the work and constitution of our Council. His lordship says: "Compare our legal system with the elaborate care and training in the medical and surgical schools. As has recently been well said by Sir Edwin Arnold, the labours of educational preparation for these professions grow year by year harder and harder—and so they ought. To be up to the high-water mark of proficiency a young doctor must to-day be a chemist, physiologist, botanist, mechanic, and many things besides. Indeed, the history of medical education in recent years, from the time when the College of Physicians and the College of Surgeons commanded the principal avenues to the profession to the changes wrought by the legislation of 1858 and 1886, affords an instructive example of the improvements that may be effected under a body such as the General Medical Council, clothed with public responsibility, and broadly representative in its character." No more striking testimony could be borne to the constitution and position of our Council than the observation of Lord Russell, a most eminent judge and a Liberal beyond question, a man of great experience, great wisdom, most prudent and careful in all his utterances. With such an authoritative expression of opinion I am content to bring my observations to a close.

On the motion of Mr. WHELMHOUSE, seconded by Sir WALTER FOSTER, a vote of thanks was accorded to the President for his address.

RESULTS OF EXAMINATIONS FOR THE SERVICES.

Tables were received showing results of competitions for commissions in the naval medical service, held on November 4th, 1895; for commissions in the medical staff of the army,

held on August 2nd, 1895; and for commissions in the Indian Medical Service, held in February and August, 1895.

On the motion of Dr. HUNTER WATSON, seconded by Dr. McVAIL, the tables were ordered to be placed on the minutes, and a vote of thanks was passed to the heads of the departments.

REPORT OF PUBLIC HEALTH COMMITTEE.

Dr. THORNE THORNE stated that in the early part of the day the following resolution had been unanimously passed:

That the Chairman be requested to represent to the President that in the opinion of the Public Health Committee the consideration of their report, the paragraph relating to which has been struck out of the provisional programme, is a matter of urgency, and that the consideration of the subject should be proceeded with during the present session.

It would be within the recollection of the Council that the matter of the public health reports was to come forward at the last meeting of the Council, but owing to the fact that a new Committee was formed, the matter was delayed for six months. Now it appeared there was to be a further delay of six months, and the Public Health Committee thought that was very unfortunate, as that delay would cause their report practically to pass into oblivion. He moved:

That the question of the consideration of the report of the Public Health Committee be taken into consideration during the present session.

Sir WM. TURNER thought that Dr. Thorne Thorne was under a slight misapprehension as to the signification of the programme of business before them, which was not a complete programme. It was within the power of Dr. Thorne Thorne to hand in to the Business Committee a motion for business on some future day.

Dr. THORNE THORNE said that the paragraph had been deliberately struck out, and he therefore assumed that it had not been considered a matter which ought to be brought forward.

The REGISTRAR said that he had merely arranged the programme of business provisionally.

The PRESIDENT said that if Dr. Thorne Thorne would give an intimation to the Business Committee they would place the matter on the agenda, if that were the wish of the Council.

This was agreed to.

CASE OF THOMAS RICHARDS.

The Council then proceeded to the adjourned consideration of the case of Thomas Richards, registered as Mem. R. Coll. Surg. Eng. 1886, Lic. R. Coll. Phys. Lond. 1888, who was summoned to appear before the Council on November 30th, 1894, to answer the following charge, as formulated by the Council's solicitor:

That, being a registered medical practitioner, he acts as cover to an unqualified person named Hugh Owen, and permits and enables him, under cover of his (Richards's) name, qualification, and presence, to attend and administer medical treatment to patients, and to carry on a medical practice, as if he were a duly qualified practitioner, the medical practice being carried on at Llanhilleth, in the county of Monmouth.

The REGISTRAR stated that having received a statutory declaration from Mr. Richards the Executive Committee were of opinion that he might be excused attendance as he resided in Wales.

On the motion of Sir WALTER FOSTER, seconded by Dr. MACALISTER, it was agreed that Mr. Richards's name be not removed from the Register.

THE EXAMINATION IN ARTS OF THE APOTHECARIES' SOCIETY.

Mr. BRIDGMAN CARTER said that very shortly after the termination of the last session of the Council he had received a letter from the Society of Apothecaries of London as follows: "June 11th, 1895. Dear Mr. Carter.—Referring to the correspondence which passed between the Society and the General Medical Council in May, 1894, in reference to the discontinuance of the examination in Arts held by the Society, and at which time the Society saw no reason for taking such a step, I have to inform you that the Court of Assistants passed a resolution on the 26th ult. deciding to discontinue the examination in question as from the end of the current year. I shall be obliged if you will in due course, as representative of the Society, communicate that decision to the General Medical Council." He moved:

That the Master's letter be received and entered on the minutes.

Dr. MACALISTER seconded the motion, which was agreed to.

DIRECT REPRESENTATION OF THE PROFESSION.

Sir WALTER FOSTER then moved:

That a committee be appointed to consider the resolution of the British Medical Association respecting the increase of the direct representation of the profession on the General Medical Council, as printed in the minutes of the Executive Committee, and to report thereon to the Council at this session.

He said that the President, in his valuable address, had already touched upon the subject, and he did not intend to argue with reference to the principle connected with which the resolution was framed. He should not have thought it necessary to put the resolution upon the paper, if the resolution of the British Medical Association had been printed on the agenda. But as that resolution had been passed by a large Association, comprising the majority of the members of the medical profession, at the largest meeting it had ever held, namely, the meeting in London this year, it was desirable as a matter of courtesy that the Council should have an opportunity of expressing by means of a committee its opinion with reference to the proposal contained in the resolution. It was not desirable that a resolution of that kind, representing the opinion of so many members of the profession, as well as that of the Council of the British Medical Association, should be passed over without any consideration whatever. That Council had given the General Medical Council an opportunity of drawing up a statement that might induce the Association to modify its action with reference to the resolution or to take steps somewhat different from those suggested by the resolution; at all events, it gave them the opportunity of asking the Council of the British Medical Association to take one direction or the other in carrying out the resolution of the annual meeting. As it stood at present, that Council was pledged more or less to proceed with the resolution and to embody such of its proposals as it thought fit in a Bill before Parliament. He would be sorry to see any conflict between the General Medical Council and the British Medical Association in the arena of Parliament, and as the medical profession felt very strongly on the point, there being a growing feeling that something should be done, not to convert that Council into a body entirely to protect medical interests, but rather to develop the body, and give the general profession a little more confidence in its action, which he felt was a legitimate desire, he thought that a Committee should be appointed to draw up a reply. That would be the most wise, and at the same time the most courteous, procedure they could adopt, and it was purely with that desire that he moved the resolution.

Mr. WHEELHOUSE, in seconding the motion, said he had himself seen how extremely strong was the feeling that the profession was not sufficiently represented on the Council. The question had been put before the Council on more than one occasion, and each time it had been met with an adverse vote; and now, seeing that the profession would not rest satisfied under that adverse vote, and seeing that the Council did not see its way to recommend the Privy Council to increase the amount of the representation, he thought with Sir Walter Foster that the appointment of a committee to go carefully and deliberately into the question, and to lay before the Council the result of its deliberations, and then ask it to come to a definite conclusion, was the best course that could be adopted.

Dr. MACALISTER hoped that the Committee would not be appointed, for the reason that the resolution was a pistol held at the head of the Council. It rested that the Council had on several occasions been asked to make a representation to the Privy Council asking to be empowered to elect direct representatives, and then it asked them to proceed to Parliament with a Bill to compel them to do so. There was no communication to the General Medical Council, no request that they should consider the subject in an abstract way, but they were asked to appoint a Committee to consider what he had called the threat, that was, to examine the pistol and see whether it was loaded or not. Nothing could be more unjustified than for the Council to do anything of the kind. If the British Medical Association, at the meeting to which Sir Walter Foster had referred, had asked the

Council to consider the question, then he admitted it would be most courteous and dignified that they should do so; but as it was, the only answer they could possibly give was, Let them go to Parliament.

Mr. BRUDENELL CARTER said that it was a wholly new doctrine that the Council owed any duties or responsibility to the British Medical Association.

Dr. GLOVER was sorry to hear the last two speakers. So far from the shape of the resolution disposing him to vote against it, it disposed him to vote for it. It was a very temperate resolution. Mr. Carter's remark that the Council owed nothing to the British Medical Association was a very unfortunate one.

Mr. CARTER: I said "owes no responsibility."

Dr. GLOVER thought it was not very good for a body like that to speak so with reference to the British Medical Association, which included the majority of the profession which they (the General Medical Council) were supposed to represent, and he very much regretted the remark.

Sir WALTER FOSTER's motion was then put to the Council and lost, 7 voting for and 21 against.

THE EDUCATION OF THE STUDENT IN PRACTICAL MIDWIFERY.

The following notice of motion by Dr. GLOVER was next considered:

That the Medical Council, having before it the petition of the British Medical Association at its late annual meeting on the inadequacy of the recommendation of the General Medical Council with regard to instruction in practical midwifery, which petition is printed in the minutes of the Executive Committee, November 26th, 1894, resolves, that in the judgment of the Council no medical authority should require less from candidates for its qualification than attendance on thirty cases of labour under the supervision of a registered medical practitioner, or three months attendance on the practice of a lying-in hospital or maternity charity under the same supervision.

Dr. McVAIL thought the matter had better come up when they received the recommendations from the Examination Committee.

Dr. GLOVER: I propose that it be received and entered on the minutes.

Mr. WHEELHOUSE seconded the motion.

Dr. MACALISTER thought it should not go on the minutes, as it was already on the minutes of the Executive Committee. At a large meeting of the British Medical Association, at which he was present, that resolution was carried instructing the Council of that body to prepare a petition and send it to the General Medical Council. The Council had not prepared a petition, but had handed the Council the resolution without giving their opinion on the matter, and the only conclusion they could come to was that the Council, having been instructed by the general meeting to prepare a petition, desired not to do so, and had handed the Council the resolution to do what they liked with. It seemed to him they had nothing to consider and nothing to put on the minutes, and that until the Council of the British Medical Association had presented a petition their hands must be held.

Sir WALTER FOSTER said he was quite prepared to go on with the matter now, but there had been an omission somewhere with reference to the petition, and until that omission was repaired they could not say they had got the petition before them.

Mr. TRALE thought the matter should not now be discussed; it had come up on that particular occasion before the British Medical Association in reference to another question which they were raising at the same time.

Sir WM. TURNER asked Dr. Glover whether, after the expressions of opinion which had been given, he would not withdraw his motion.

Dr. GLOVER thought the objection was a technical one, but as bringing the subject forward at the time appeared to prejudice its calm consideration he would give way and withdraw his motion.

This the Council agreed to.

ERASURE OF NAMES FROM THE "REGISTER."

Dr. GLOVER, in accordance with notice, asked whether the President of the General Medical Council had heard finally from the Registrar-General since his promise to consider the

forwarding to the local registrars a notice of the erasure of any name from the *Medical Register*.

The REGISTRAR said that on June 21st the Registrar-General had written stating he would consider the matter, and no further communication had been received. He had tried to estimate the cost, and thought it would not be more than £350 including postage.

Sir WALTER FOSTER said that at the time he had been a member of the late Government and had endeavoured to get the matter dealt with. The cost was then estimated at £600, and he had had no opportunity of submitting any amended estimate to the Treasury owing to the resignation of Lord Rosebery. The best course now would be to write letters to the Treasury urging the request, and pointing out that the cost would not be £600, but probably about half that amount.

Dr. GLOVER proposed that the President be requested to communicate further with the Registrar-General, with a view to securing that local registrars be informed of the erasure of any name from the *Medical Register*.

Sir WALTER FOSTER seconded the motion, which was agreed to.

DISCIPLINARY FUNCTIONS OF QUALIFYING MEDICAL AUTHORITIES.

Dr. GLOVER then moved:

That it be an instruction to the Executive Committee to revert to the consideration of the subject of the disciplinary functions of the qualifying medical authorities and of the General Medical Council, and to report to the Council at its next meeting on the best means of further defining and confirming these functions and bringing them into harmonious and efficient co-operation.

He thought the matter was one which deserved the serious consideration of the Council.

Dr. THORNE THORNE seconded the motion.

The resolution was carried *nem. con.*

THE CASE OF ROBERT MASTERS THEOBALD.

The Council considered, *in camera*, the application of Robert Masters Theobald for a rehearing of his case. Mr. Theobald's name was removed from the *Medical Register* on December 3rd, 1894, for having, in the opinion of the Council, committed the offence of publishing and circulating a book named *Electro-Homoeopathic Medicine*, containing a description and recommendation of the so-called electro-homoeopathic cures and medicines of Count Mallet, and in which it was suggested by Mr. Theobald to persons suffering from disease that they should adopt the so-called cures and medicines.

On the readmission of strangers, the Council's solicitor, Mr. MUR MACKENZIE, informed Mr. Theobald that the Council had considered his application, and that they declined to declare the proceedings in the previous case null and void, to restore his name to the *Register*, or to rehear the case.

Mr. THEOBALD asked whether there was any method by which he could have his name restored to the *Register*.

Mr. MACKENZIE said that he could only do so by complying with the Standing Orders of the Council.

Mr. THEOBALD submitted that he had fulfilled the conditions by signing an application for the restoration of his name, and by filling up the necessary forms attested by a Justice of the Peace.

Mr. MACKENZIE said that it was a condition, both under the Standing Orders of the Council and under the Act, that before he could have his name placed on the *Register* he must show that he was in possession of a diploma or not, and that he had very strong and valid arguments in support of that view. Was it the opinion of the Council that it was a condition precedent to his name being restored to the *Medical Register* that he should obtain his restoration as a Member of the Royal College of Surgeons?

Mr. THEOBALD said that the decision of the Council was illegal, inaccurate, and altogether wrong. He submitted that the Council had power to restore his name to the *Register* whether he was in possession of a diploma or not, and that he had very strong and valid arguments in support of that view. Was it the opinion of the Council that it was a condition precedent to his name being restored to the *Medical Register* that he should obtain his restoration as a Member of the Royal College of Surgeons?

Mr. MACKENZIE said that that was so.

Mr. THORALD said that that being the case, he would ask the Council to furnish him with a recommendation to the Royal College of Surgeons to the effect that he was entitled to the restoration of his diploma, for unless he had such a recommendation it would be useless to make any application to that body.

The PRESIDENT said that it was not in the power of the Council to make any such recommendation.

Mr. THORALD asked whether he had a right to appeal to the Council against the decision of the Royal College of Surgeons.

The PRESIDENT said that he had no such power.

Mr. THORALD again protested that it was in the power of the Council to restore his name to the Register, and that they were acting illegally in not doing so.

The Council then adjourned.

Wednesday, November 27th.

SIR RICHARD QUAIN, Bart., in the Chair.

CONJOINT EXAMINATION OF THE ROYAL COLLEGE OF SURGEONS OF IRELAND AND THE APOTHECARIES' HALL OF DUBLIN.

Mr. WHEELHOUSE asked permission to make a correction to the speech which he had addressed to the Council on June 6th last, in which he was unfortunately led to make a statement which he had since understood was incorrect. In moving the adoption of the report of the Royal College of Surgeons of Ireland and the Apothecaries' Hall of Dublin he had stated that he had visited the last two examinations of the Board and had found that great improvement had been made, and that the third examination was more perfect than the first. "Efforts have been made to improve it; with the exception of medicine they were tolerably satisfied with the examination. The examination was well conducted, but the candidate to whom they took exception, although well versed in theory, knew nothing about practice." So far he thought nobody could take any objection whatever to that description of the examination, but then unfortunately he went on to add, "and he was now passed as a qualified man." It had been brought to his knowledge that that was an entirely incorrect statement, that that gentleman was not passed as a qualified man, that he was not a qualified man at this moment, and that he was not qualified because, though he had passed in medicine as described in the report, he had been already stopped at his examination previously in pathology and also in surgery. It was said that by what he then stated he had greatly and seriously prejudiced the minds of the Council in their consideration of the Irish question. If he had done so, he could only entreat the Council to dismiss all that he had said concerning the candidate's being a qualified man out of their minds, and simply to look at the report as it stood. He had been led into the mistake by the fact that he saw the candidate examined at a Final Examination. He thought a Final Examination meant the last, and that when a man had passed it he would be qualified, but he had forgotten that in that Final Examination, or as part of it, the candidate had been examined in pathology, and stopped at that point. It was also said that besides having prejudiced the mind of that Council as against the Committee of Management at that examination, he had also prejudiced the minds of the Privy Council. He could not think that that was so, because he imagined that the Privy Council would have the report before it, and would judge of the question purely upon the merits of that. He could not fancy that any few words he might have spoken to the Council would ever reach the Privy Council at all. He offered an apology to the combined examiners of the College of Surgeons, Ireland, and the Apothecaries' Hall, Ireland, for the mistake which he had made.

The PRESIDENT: Do you desire that that should appear in the minutes?

Mr. WHEELHOUSE: I leave that entirely to the Council.

SIR WILLIAM TURNER said that it was only fair that it should be stated that Mr. Wheelhouse admitted that he had made a mistake and explained how it had arisen.

The PRESIDENT: That would be quite enough.

SIR PHILIP SMYLY asked to be allowed to make a few remarks upon the general question, as to what effect the mistake

had had upon the report sent to the Privy Council; but after some little discussion

The PRESIDENT said it had been decided that the Council should send a report to the Privy Council, which the Privy Council had received and acted upon, and they could not go back upon that; it was quite impossible. The President then asked the Council if they wished to hear Sir Philip Smyly, upon which there was no voting.

The PRESIDENT: There is no voting upon it, and I must therefore ask you to stop.

SIR PHILIP SMYLY asked if it should be noted that his statement was not heard. He thought that should be done. He moved that Mr. Wheelhouse's explanation of the mistake made by him in his speech to the Council be entered on the minutes.

The PRESIDENT said it had already been arranged that that should be done.

SIR PHILIP SMYLY: Not by the Council, sir. I want to speak upon it, and to show you that we ought not to have been reported to the Privy Council; and that it was due to the mistake made by Mr. Wheelhouse that we were so reported.

The PRESIDENT: Where is the Chairman of the Examination Committee?

SIR DYON DUCKWORTH: That little *lapse* which Mr. Wheelhouse made was a perfectly microscopic affair, which has been made to assume a large mass now. It is grotesque.

The PRESIDENT said that the following resolution was the one which empowered the Council to send to the Privy Council:

That it appears to the Council that the standard of efficiency in the subject of medicine required from the candidates at the qualifying examination held by the Conjoint Board of the Royal College of Surgeons, Ireland, and the Apothecaries' Hall, Dublin, after four special inspections, has been found insufficient.

That was a general condemnation.

SIR PHILIP SMYLY said that was what he objected to—it was not a general condemnation; the last report was on the single question that the man was given a pass mark in clinical medicine—a very small item indeed—and it was distinctly upon that that the vote was taken.

The PRESIDENT said that if Sir Philip Smyly would give notice that he would move that the Council should rescind the resolution that was passed on that occasion, and that that be communicated to the Privy Council, they could understand it, but really to go back debating what they had already decided on, and what the Privy Council had decided, was quite out of order, and he must appeal to him not to go on.

The Council then proceeded to consider a communication from the Privy Council as to the continuation of the examination by the Conjoint Board of Surgeons and Apothecaries' Hall, Ireland, of candidates who may claim to be examined as having been previously engaged in preparing for examination and already passed part of it.

The REGISTRAR said that there was no notice of motion on the programme in reference to that, and if there was nothing further to be said they must pass on to the next matter.

The PRESIDENT said he desired to point out to the Council that they were asked to inform the Privy Council of the action they proposed to take upon that subject. There was no question whatever that legally and in every other sense the Conjoint Board in Dublin was at an end. If it had ceased to exist it could not go on for any purpose whatever; they could not qualify it saying that it should continue to exist for examining candidates who had a claim upon them. The simple course would be for the College of Surgeons to intimate that they intended to withdraw, but would not do so until those people had been examined, and therefore the position they would be in now would be to withdraw their resignation from the Conjoint Board, and to say that the Board should continue to examine candidates who had any claim to be examined for a certain number of years. Otherwise they might go on for the next fifty years if the candidates came up and kept the Board going. The Council would probably approve of the College of Surgeons withdrawing their resignation, and allowing the Board to go on as it was, for say four or five years, no candidates being admitted, except those who had a special claim for examination, and that at every examination an inspector from the General Medical Council should be present. That would

probably be the reply to send to the Privy Council, and if the Council would direct the President to make a communication to that effect, that would settle the matter.

Sir PHILIP SMYLY said he thought it would be found that in the notice sent to the Apothecaries' Hall it was distinctly stated that the interests of those candidates who had entered would be taken care of. As to recombining with the Apothecaries' Hall, he did not think his colleagues would do that. The report to the Privy Council had nothing whatever to do with their separating from the Apothecaries' Company; they had given notice of that considerably before there was any report to the Privy Council at all. The number of candidates who had claims was possibly sixty, but practically he thought he was right in saying that there would not be more than twenty or thirty.

Sir WILLIAM TURNER said that the first point which they had to consider was how long the conjoint examinations were likely to be continued, and the second was whether they were prepared to offer any explanations upon the letters submitted to the Lord President by the Royal College of Surgeons, Ireland, and Apothecaries' Hall, Dublin, which were forwarded to the General Medical Council on August 10th last.

Sir PHILIP SMYLY said he had not been authorised to give an opinion by his Council, and thought that the limit of time should be fixed by the Council's legal adviser.

Dr. MACALISTER said that any claim for examination on the part of the candidates would be against the Conjoint Board, not against the College of Surgeons. If the Conjoint Board said: "We cease to exist for all purposes," there was no body for a candidate to bring an action against. As a matter of fact, however, they had not said they ceased to exist for all purposes.

Dr. CHARLES MOORE said that he had a letter from the governor stating he was to be guided by the Council in regard to those outstanding men; 159 men had offered themselves for examination in the last six years, out of them 97 passed completely, and there remained 62, of whom 6 had already gone to other bodies, leaving 56, and, as there were only 56 men to pass, six years would be ample time. He had the authority of his Council to leave it to the President to fix the time.

Dr. MACALISTER proposed:

That the Conjoint Board in Ireland of the Royal College of Surgeons and the Apothecaries' Hall be requested to furnish the Council with a list of the names of the candidates, with the dates of their admission, who have already passed some of the examinations of that Board, but had not, on July 1st, 1895, completed the series of examinations required for the Board's qualification.

Sir WILLIAM TURNER seconded the motion, which was agreed to.

Dr. MACALISTER then moved, and Sir WILLIAM TURNER seconded:

That the President of the Council be requested to inform the Lord President of the Privy Council that the Council are legally advised that the Conjoint Board of the Royal College of Surgeons of Ireland and the Apothecaries' Hall, Dublin, has not yet ceased to exist so far as regards students who have entered for the examinations of the Board before July 1st, 1895; that it appears to the Council that all existing claims for admission to the examinations of the Conjoint Board should be exhausted within six years from the present date. That the Council understands that the two bodies constituting the Conjoint Board are prepared to carry out the arrangements necessary for meeting these claims for examination, of which there are probably about sixty.

This was agreed to.

Sir WILLIAM TURNER said that, having now disposed of the first question raised in the Lord President's letter, they must now look at the second question: "The Lord President desires to be informed whether the General Medical Council have any observations to offer on the explanations submitted to his Grace by the Royal College of Surgeons and the Apothecaries' Hall, Dublin, which were forwarded to you in my letter of August 10th last." He would ask the Registrar to read the reasons given by Mr. Woods to show that the Conjoint Board had not merited condemnation, and the reasons given by Mr. Tichborne to a similar effect.

The REGISTRAR: The reasons given by Mr. Woods are these: "The Council confidently hopes that it has not merited this condemnation, for these reasons: That the report had not been seen by the Council at all when the

General Medical Council passed judgment; that the Council of the College was entitled to have time for the consideration of the report and the preparation of a reply, and that no time was given for these purposes; that the report on the subject of medicine is based upon a difference of opinion between the examiners and the visitor and the inspector, and the Council points out that the examiners were entirely competent and experienced; that the judgment of the General Medical Council was influenced by emphatic statements which have been shown to be absolutely without foundation; that the union known as the conjoint scheme of the Royal College of Surgeons in Ireland and the Apothecaries' Hall, Ireland, has ceased to exist, and that when the General Medical Council reported the examination to the Lords of the Privy Council as insufficient, it knew that the scheme was within a few days of terminating." Mr. Tichborne had written as follows: "The Hall, therefore, submit that any imperfection in the conduct of the examinations has been due to causes which can be remedied, and to difficulties which can be overcome. That their undertaking to maintain a sufficient standard of medical examination should be accepted, and assistant surgical examiners be appointed by the General Medical Council. That nothing has been done by the Hall meriting disfranchisement. In several respects the examinations have been commended, and the only point of unfavourable comment in the last report of the visitor and inspector has arisen from what seems to be an error. If there is anything in the case on behalf of the Apothecaries' Hall as embodied in this letter, and the accompanying Appendices 1 and 2, which does not clearly afford a complete answer to the representation made by the General Medical Council to the Privy Council, the Hall would ask your Grace's permission to be heard by counsel on their behalf before the Privy Council."

The PRESIDENT said that Sir Philip Smyly might now make any statement he wished.

Sir PHILIP SMYLY said that the College of Surgeons had always supplied good examiners, and on the last two reports the examination in medicine was declared satisfactory, and only insufficient upon the question of marking. The statement that the College of Surgeons had not time to consider the report was absolutely true. The Examination Committee was sitting at the time the report was first handed to them; it was not sent to the two bodies to be considered, and the report was considered so favourable that Dr. Moore and he sent a wire to the Conjoint Board to accept the report of the visitor, as it was most favourable. They never thought that the fact of the marking would have the effect of causing the examination to be reported as insufficient, even if as was supposed from the statement of Mr. Wheelhouse the candidate had been passed. The visitor and inspector said: "For this reason, although we have no fault to find with the actual examination itself, the fact that a candidate was passed who exhibited gross ignorance of clinical medicine compels us to report that in medicine the examination was not sufficient. In other subjects we report that the Final Examination was sufficient." It was also stated that the examination itself itself was in every respect a most satisfactory one, and the marks awarded were strictly equitable. Under those circumstances, he thought that Dr. Charles Moore and he were justified in believing that the report of the Examination Committee would have been favourable. Their contention was that the adverse vote taken in the General Medical Council was taken upon an erroneous statement. Mr. Wheelhouse had explained that there was no foundation for the statement which he had made.

Mr. WHEELHOUSE said he had explained that there was no reason for his saying that the men had passed into the profession, but Dr. Duffey and he adhered entirely to the word "passed" as referring to the clinical examination, and he had nothing to say whatever with reference to that.

Sir PHILIP SMYLY said the statement that the men had passed into the profession was quite sufficient to mislead the other members of the Council. In the legal notice to the Apothecaries' Hall it was distinctly stated that the interests of those who had entered up to the dissolution of the body were to be taken care of.

Sir DYCK DUCKWORTH said that the report was founded upon four inspections, not on one inspection.

Dr. MACALISTER moved, and Sir WILLIAM TURNER seconded:

That the President of the Council be requested to inform the Lord President of the Privy Council in reply to the communications of the Royal College of Surgeons, Ireland, and Apothecaries' Hall, Dublin, first, that the opinion of the General Medical Council as to the standard of proficiency in medicine required by the Conjoint Board was based on the results, not of one inspection only, but of four special inspections and visitations; that the remarks made in the communications referred to have been considered by the Council, but they see therein no reason to alter their opinion as to the standard in question.

Dr. CHARLES MOORE said he wished to point out that the Apothecaries' body had suffered under peculiar difficulties in obtaining examiners in medicine. At last they had brought a gentleman 200 miles to examine, and he held that the last two examinations of that gentleman and by his colleague, a professor of the Royal College of Surgeons, had been pronounced sufficient in every respect except in one point about which they had heard. He would move as an amendment:

That the printed reports of the General Medical Council do not justify a condemnation of the Conjoint Body of the Royal College of Surgeons and the Apothecaries' Hall inasmuch as several other bodies had been pronounced insufficient in most important particulars but have not been condemned.

Sir PHILIP SMYLY seconded the motion, which was lost, two only voting for it.

Dr. MACALISTER's proposition was then carried.

On the motion of Dr. MACALISTER, seconded by Mr. TEALE, it was agreed:

That the Lord President be further informed that if and so long as the Conjoint Board's examinations continue to be deemed by the Privy Council to be qualifying examinations under the Medical Act, the Medical Council is unable to secure the maintenance of the standard of proficiency, otherwise than by repeated inspection and visitation of the Board's examinations.

Dr. HERON WATSON proposed that a deputation be sent to the Lord President.

Sir DYCK DUCKWORTH seconded the proposition, which was put to the Council and lost.

ASSISTANT EXAMINERS IN SURGERY FOR APOTHECARIES' HALL, IRELAND.

The Council then proceeded to the consideration of the following application from the Apothecaries' Hall of Ireland for the appointment of assistant examiners in surgery:—"Dear Sir, I am directed by the Governor and Court of the Apothecaries' Hall, Ireland, to petition the Council to appoint two examiners in surgery, under the provision of the Medical Act, 1868, as their conjunction with the Royal College of Surgeons, Ireland, has ceased in July, 1895. If permission is granted, the Court herewith submit two names for the approval of the Council, or will receive two names from the Council if so directed. I am requested to ask you to place the above before the Council at ensuing meeting. The Governor and Court beg to submit to the General Medical Council the following names as suitable examiners in surgery, and they have intimated their willingness to act—Francis T. Houston, M.D., R.U.I., F.R.C.S., and M.R.C.S., Surgeon to Adelaide Hospital; F. Conway Dwyer, M.B., Bae. Surg. F.O.D., Surgeon to Jervis Street Hospital.—Faithfully yours, ROBERT MONTGOMERY, M.R.C.S., Secretary."

Dr. EATY TUCK said that they had no evidence that the Apothecaries' Hall had fulfilled the requirements of the Medical Act of 1868, which stated that they should exhaust all the means in their power to join with another body before applying for the appointment of examiners; and he wished to know whether the request was in order.

Dr. MACALISTER said that as they had now agreed that the Conjoint Board was not extinct and would go on for some years, it was impossible for them under the law to appoint examiners to the Apothecaries' Hall separately. By the statute they were barred from making the application.

Dr. GLOVER proposed that the opinion of the legal adviser be taken on the matter.

Sir WILLIAM TURNER thought it would be satisfactory if Dr. Moore could state whether the Apothecaries' Hall had exhausted all means.

Dr. CHARLES MOORE said that they had applied to the

College of Physicians and the University of Dublin with regard to combination, and had been refused.

Sir WILLIAM TURNER thought they ought to have a written statement to that effect from the Apothecaries' Hall.

Dr. CHARLES MOORE said he would wire that evening, and would probably get an answer on Thursday morning.

Mr. BRUDENELL CARTER thought that the verbal information given to them by one of their colleagues was sufficient.

The PRESIDENT: Those who are of opinion that the Apothecaries' Hall has used its best endeavours to obtain combination, on the report of Dr. Moore, please signify the same.

Agreed to.

Dr. MACALISTER moved, and Dr. GLOVER seconded:

That Mr. Muir Mackenzie be asked to advise the Council whether, under Section 6 of the Medical Act, or other legal provision, the Council has power to appoint additional examiners in surgery for the Apothecaries' Hall in respect of students entering after July 1st, 1895.

This was agreed to.

Sir WILLIAM TURNER said that, as the matter would be adjourned till Friday, a statement might be asked for from the Apothecaries' Hall, to the effect that all means of endeavouring to combine with another body had been exhausted.

ALTERATIONS IN THE "MEDICAL REGISTER."

Dr. HERON WATSON moved and Sir WILLIAM TURNER seconded the following motion:

That the Council direct that the changes made by the Registrar in the General Register, whether as respects the addition or removal of names or the alteration of names or residences, be communicated twice in every month to the branch registrars in Scotland and in Ireland, and that a like intercommunication of alterations in English and Irish registers be communicated to the Irish and Scotch registrars respectively, with a view to such alterations being entered by them in an interleaved copy of the printed Medical Register supplied to the branch registrars when such Register is annually made.

CASE OF J. C. LINDOP.

The Council then proceeded to the case of John Crump Lindop (registered as Mem. R. Coll. Surg. Eng., 1862; Lic. Soc. Apoth. Land., 1863), who was summoned to appear before the Council on June 1st, 1895, to answer the following charge, as formulated by the Council's Solicitor, on the complaint of the Medical Defence Union: "That during the months between December, 1894, and April, 1895, inclusive, or some part of such period, he acted as cover to an unqualified person named Wadlow, residing and carrying on medical practice at Oundle Villa, Peterborough, and by so acting as cover to him, and by his presence and the aid of his professional qualifications, enabled the said unqualified person to carry on medical practice, and attend and administer medical aid and medicines to patients, and recover charges therefor as if he had been duly qualified."

It was stated that Lindop was summoned on May 6th, 1895. The summons was sent in a registered letter, which was returned by the Dead Letter Office about May 14th, 1895.

Mr. BRUDENELL CARTER thought that the legal advisers should be asked to bring the documents to-morrow, when they would be able to tell the Council whether there was sufficient ground on which Lindop could be taken off the Register.

This was agreed to.

The Council then adjourned.

Thursday, November 29th.

Sir RICHARD QUAIN, Bart., in the Chair.

CASE OF GEORGE FRANCIS MCCARTHY.

The Council proceeded to the adjourned consideration of the case of George Francis McCarthy, who was summoned before the Council on June 1st last for having acted as cover to an unqualified person named Francis Morley Coppen. At that session the Council passed a resolution that in their opinion he (George Francis McCarthy) had committed the alleged offence, but adjourned the further consideration of the case to the present session. The Council had now received a testimonial from Mr. F. W. Brookes, M.R.C.S., L.S.A., stating that, during the last six months, Mr. McCarthy had con-

ducted his practice entirely by himself, and with every regard to professional etiquette. Mr. McCarthy appeared in person and gave an assurance that he would not in future employ any unqualified assistant in his practice. The Council deliberated in *camero*, and on the readmission of strangers the President informed Mr. McCarthy that the Council had taken a merciful view of his case, and that in view of his statement that he would not employ an unqualified assistant in future, and the commendatory testimonial from Mr. Brookes, they had decided not to remove his name from the *Register*.

THE APPLICATION FROM THE APOTHECARIES' HALL OF IRELAND.

The President read a communication from Dr. Moore, stating that the Apothecaries' Hall of Ireland had used their best endeavours to obtain a Conjoint Board of the Apothecaries' Hall and the Universities in Ireland, but that they had failed to do so. The letter was entered on the minutes.

REPORT OF THE EXAMINATION COMMITTEE.

On the motion of Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, the Council went into Committee to consider the report of the Examination Committee embodying specific recommendations as to the Final Examinations in Medicine, Surgery, and Midwifery. The first recommendation, moved by Sir DYCE DUCKWORTH, and seconded by Mr. BRYANT, was:

That fixed intervals of time between the several examinations should be maintained, and that two academic years should intervene between the date of passing the last examination in Anatomy and Physiology and that of admission to the Final Examination in Medicine, Surgery, and Midwifery.

Dr. MACALISTER moved the following amendment, which was seconded by Dr. BRUCE:

That before any student is admitted to the Final Professional Examination he shall be required to present evidence of at least two years' clinical study subsequent to the passing of his examination in anatomy and physiology.

The amendment, on being put, was declared to be lost, and Sir Dyce Duckworth's resolution was agreed to.

The next recommendation, proposed by Sir DYCE DUCKWORTH, and seconded by Mr. BRYANT, was:

That the extreme subdivision of examinations, and particularly of the Final, as now permitted by some Boards, should not be sanctioned.

Dr. McVAIL moved, and Dr. CAMERON seconded, the following amendment:

That in the Final Examinations the subjects of Medicine, Surgery, and Midwifery shall all be passed at the same time.

The amendment, on being put, was lost, and the original motion carried.

[The remainder of the report will be published next week.]

LITERARY NOTES.

IN a recent number of the *New Orleans Medical and Surgical Journal* Mrs. H. M. Plunkett gives an interesting account of the earliest attempts to check the ravages of small-pox in America. In 1721 a fearful epidemic of small-pox visited Boston. Shortly before this the news of inoculation having been brought from Turkey to England by Lady Mary Wortley Montagu had crossed the Atlantic, and Cotton Mather, who was himself an example of what he calls the "angelical conjunction" of clergyman and medical practitioner, was much interested in the matter. It would appear, however, that he had already heard of inoculation for small-pox from another source, for he says:

I was first informed of this wonderful practice by a Garamantee servant of my own, long before I knew that any Europeans or Asiatics had the least acquaintance with it, and some years before I was enriched with the communications of the learned foreigners, whose accounts I found agreeing with what I received of my servant, when he showed me the scar of the wound made for the operation, and said that no person ever died of small-pox in their country that had the courage to use it. I have since met a number of these Africans, who all agree in one story: "that in their country grandy many dy of small-pox. But now they learn this way. People take the juice of small-pox and cutty skin and put in a drop. Then he put by a little sticky sticky, then very few little things like small-pox. And nobody dy of it. And nobody have small-pox any more." Thus in Africa, where the poor creatures die of small-pox like rotten sheep, a merciful God has taught them an infallible preservative. 'Tis a common practice, and attended with constant success.

Mather got together the doctors of Boston, then six in number, at a time when prayers were being asked for in the churches for persons smitten with small-pox at the rate of a hundred a day, and recommended them to try inoculation. Only one of them, however, followed the advice. This was Zabdiel Boylston, who, on June 27th, 1721, inoculated his only son. Afterwards, in the course of the epidemic, 240 were inoculated, of whom 6 (less than 3 per cent.) died, while the mortality among those who took the disease in the natural way was between 14 and 15 per cent. Dr. Boylston was mobbed, and Cotton Mather himself had a hand-grenade thrown in at him through his window. In spite of popular prejudice, however, many New England preachers were enlightened and courageous enough to advocate the practice in the pulpit. Vaccination was introduced into America in 1800, and in July of that year Dr. Benjamin Waterhouse of Cambridge, Massachusetts, submitted four of his children to the new process.

The *International Medical Magazine* for October contains an article on "Medicine and Surgery among the Australian Aborigines" by Dr. J. Steele Robertson, Secretary of the Medical School of the University of Melbourne. The aborigines appear to owe the introduction of most of the fatal diseases which are steadily wiping them out of the scheme of creation to the white man. Small-pox was introduced in 1789 by an English ship. Syphilis spread rapidly owing to the white convicts' lust and the accommodating habits of the natives. The degenerate aborigines who wear clothes fall an easy prey to chest diseases. The therapeutics of the native doctors consist chiefly in dances, incantations, and sleight of hand, by which the practitioner pretends to extract stones, chips of wood, bits of bone, etc., and triumphantly displays them as the cause of the trouble. Among these poor aborigines, however, as among more civilised people, faith often makes sick folk whole. Dr. Robertson thinks it strange that a native medicine man, though knowing himself to be a humbug, will yet call in a professional brother when he is himself ill. But have not scientifically-trained doctors—yes, even leaders in medical Israel—been known to turn in despair to quackery when all else had failed? The doctor, whether savage or civilised, is after all human, particularly when his own person is in question. Dr. Robertson gives some interesting details as to native therapeutics. Of surgery, beyond the use of ligatures, splints, the lancet, and the canterbury, they know practically nothing.

In the *Journal of the American Medical Association*, vol. 21, p. 577, Major and Surgeon Charles Smart, of the United States Army, published an interesting article on the Army Medical Museum. The Museum came into existence during the Civil War; in response to a circular a large amount of material illustrative of gunshot fractures and of camp diseases was accumulated and sent to Washington. This material was arranged by Surgeon J. H. Brinton, and the Museum was opened in Ford's theatre in 1867. At this time the Museum and Library received official recognition from Congress by the authorisation of certain expenditures in their behalf among the miscellaneous expenses of the Medical Department. Major Smart speaks of the great need of a good illustrated catalogue of the Museum; although the Surgeon-General has more than once urged the necessity of this, his efforts have been unsuccessful. The Museum was housed in Ford's theatre for over twenty years. In this old building the danger from fire was so great that the President of the United States embodied a recommendation for a fireproof building in his message to Congress. In March, 1885, an appropriation of 200,000 dollars was approved for a fireproof building, but as the original plans were based on an estimate of 250,000 dollars many changes had to be made involving a reduction in size and the omission of ornamentation. The new building in the Smithsonian grounds was opened in February, 1888. In June, 1894, the Museum contained 32,269 specimens; of these, 12,249 were pathological, 4,376 illustrated human anatomy, 1,717 comparative anatomy, 12,033 microscopy, and 1,894 were classed as miscellaneous.

Dr. George S. Keith's book, *A Plea for a Simpler Life*, which was first published by Messrs. A. and C. Black in the middle of September, is now in its third edition.

ROYAL COLLEGE OF PHYSICIANS.

NEW REGULATIONS FOR THE EXAMINATIONS OF THE JOINT BOARD.

An extraordinary Committee of the College was held on November 22nd, Sir J. RUSSELL REYNOLDS, Bart., President, in the chair.

The President announced that Dr. J. F. FAYNE had been appointed to deliver the next Harveian Oration, and he also made known to the College that a meeting had been held at the University of London on the previous day, under the presidency of Sir James Paget, of the delegates from the medical schools and other bodies interested, respecting the deputation to the Government to ask them to appoint a Statutory Commission to carry out the scheme for the new University.

The College seal was set to the deed relating to the Weber-Parkes Prize Trust.

A communication was received from the Royal College of Surgeons relating to recent proceedings of the Council of that body, and more particularly to the reply sent to the memorial of the teachers of the London School of Medicine for Women.

A letter was received from Sir Arthur Watson, Bart., Q.C., who had been one of the standing counsel to the College since 1873, announcing that he had retired from practice, and could therefore no longer serve the College in an official capacity, and expressing his thanks for the courtesy and consideration he had always received from the College.

The resignation was accepted with great regret, and thanks were accorded for his long services.

On the motion of Dr. J. K. FOWLER, seconded by Dr. VIVIAN POORE, it was resolved:

That leave be given to the Fellows' Club to continue to hold their dinners in the College.

The report on the arrangements of the examinations under the regulations of the five years' curriculum was then taken into consideration, the REGISTRAR giving a brief but lucid statement of the circumstances in which the need for fresh legislation on this subject had arisen.

Dr. GRIFFITH objected to the permission given to a candidate to go up for his examination in midwifery at the end of his fourth year; this was a very special subject, and men could only learn it after they had studied medicine and surgery. He noticed that amongst the delegates who had prepared these resolutions there was no representative of midwifery.

Dr. LIVING pointed out that there had been no representative of that subject amongst the delegates because there had been no intention of altering the scheme in so far as it related to midwifery, and as a matter of fact no change had been made in that respect.

Dr. CURSOW approved of the elimination of the examination in elementary anatomy, but said that the effect of this would be to cut off the first year of medical study in many instances, as the boy would be able to be registered and pass in the remaining subjects from his school. He objected to the separate paper on pharmacology, and moved an amendment cutting out this subject from the final examination and including it in the examination on medicine.

This was not seconded.

Dr. PAYNE thought it would be exceedingly difficult to limit the examination to pharmacology, and that it would be much better to include therapeutics with it. He also thought that the subject of pathology deserved more attention; only ten minutes of *visu vocis* were allotted to practical pathology both for the recognition of naked eye and microscopical specimens, which he thought was not fair to candidates.

Dr. FOWLER did not consider that pharmacology ought to be put on a level with the other great subjects and made an integral part of the examination, especially as it afforded another opportunity at which a man might be rejected. He should much have preferred to see the subject included in the papers on medicine, which might be extended to six questions each, but it was so important to pass the report that he would not move any amendment. He hoped the schedule would be leniently interpreted by examiners.

Dr. E. WATTS said he would be pleased to see the subject of

pharmacology eliminated, but he would accept it rather than let the scheme fall through or be delayed, for as a whole it had very decided merits; an undue proportion was being given to this subject, and there seemed to him to be an entire loss of perspective in this matter. The schedule, too, was a dangerous one, for the chief use of a schedule was to act as a check and restraint upon examiners, and this it would not do.

Dr. OWEN considered that it was a most important thing that pharmacology should be retained as the subject of a separate paper, and he protested against eliminating it at a small meeting of the College, and when not one teacher of the subject was present. It was of the utmost importance that a man when he got into practice should have some intelligent idea of the treatment of disease, and this hitherto he often lacked.

Dr. EWART entirely agreed with Dr. Owen in his defence of pharmacology, and then protested against the appalling ignorance displayed by candidates in the matter of writing prescriptions, which he said was due to the abandonment of Greek, the natural language of the profession, as a compulsory subject, and he hoped that some steps would be taken to remedy the defect.

Dr. GRIFFITH then moved an amendment, the effect of which was that a man could not be examined in midwifery until the end of his fifth year; this was subsequently seconded by Dr. PLAYFAIR.

Dr. LIVING said that there had always been a paper on *materia medica*, and he believed that the new paper would be very similar, though under a different name.

Dr. POORE, as one of the delegates who had drawn up the report, said that they had left the schedules untouched, and had also left the question of the examination in midwifery exactly as it was settled by the College three years previously.

Dr. CAYLEY observed that if they put the examination in midwifery at the end of the fifth year, it was practically adding six months to the curriculum, as students always took the subjects up separately.

Dr. CHURCH, premising that he did not know exactly what was meant by pharmacology, expressed the opinion that the best plan would be to accept the report, but at the same time to communicate to the College of Surgeons an expression of opinion that it was desirable that the subject should be included under medicine, and he moved an amendment to that effect.

After some remarks from Drs. COUPLAND, CHAMPNEYS, TAYLOR, and several who had already spoken,

Sir W. BROADBENT said that they ought not to discuss details, and they would be running a great risk if they did anything other than adopt the report and let it be tried.

Dr. Church's amendment was then put and carried.

Dr. Griffith's amendment, after some observations by Drs. PAYNE, HORROCKS, and TAYLOR, was put and lost.

Dr. Church's amendment was then put as a substantive motion, and agreed to.

Dr. CHAMPNEYS then moved the following resolution, of which he had given notice:

That a committee be appointed to prescribe the proper conduct of a practitioner when brought into relation with a case of acknowledged or suspected criminal abortion, with power to take legal advice.

This was seconded by Dr. PHILLIPS.

A suggestion of Dr. WATT BLACK to substitute "define in a legal sense" for the word "prescribe" having been accepted, and after some comments had been made by Drs. LEE and PLAYFAIR, the motion was agreed to, and a committee appointed, consisting of the Censor, Dr. Champneys, Sir John Williams, and Dr. Watt Black.

The following is the text of the new regulations referred to above, and contained in a report, dated November 11th, 1896, of the delegates appointed by the two Royal Colleges to consider the arrangements of the examinations under the regulations of the five years' curriculum.

1. That the Third and Final Examinations in Medicine and Surgery be replaced by a single Final Examination in each subject at the end of the fifth year of study, the examination taking practically the same form as at present, but with increased time for the clinical part of the examination. (The

Examination in Medicine and Surgery may be taken separately as at present).

2. That the time of the clinical part of the examination in each subject be extended to thirty minutes.

3. That an interval of two years, as under the four years' curriculum, be required between the Anatomical and Physiological Examination and the Final Examination.

4. That the Examination in Midwifery may be passed at any time after the completion of the fourth year of professional study, provided one year has elapsed since passing the Anatomical and Physiological Examination.

5. That the Examination in Pharmacology may be passed at any time after the completion of the fourth year of professional study, provided the Anatomical and Physiological Examination has been passed.

6. That the Examination in Practical Pharmacy may be passed at any time after registration as a medical student.

7. That no candidate be rejected for a longer period than three months except upon the special resolution of the examiners.

8. That the subject of elementary anatomy be eliminated from the First Examination.

The report recommended further that the remuneration of the Examiners in Medicine and Surgery should be the same as at present, and made certain suggestions as to the apportionment of expenses between the two Colleges.

REVISED SCHEME

The following is the scheme of the Final Examination submitted by the delegates as embodying the foregoing recommendations, namely:

FINAL EXAMINATION.

The Final Examination shall consist of four parts, namely:

I. Medicine, including Medical Anatomy, Pathology, and Therapeutics. Questions will also be set in Forensic Medicine and Public Health.

II. Surgery, including Surgical Anatomy and Pathology.

III. Midwifery and Diseases of Women.

IV. Pharmacology.

Candidates will be admissible to Parts I and II on producing evidence of having completed the curriculum of professional study, provided not less than two winter and two summer sessions have elapsed since passing in Anatomy and Physiology at the Second Examination.

Candidates will be admissible to Part III on the completion of four winter and four summer sessions of professional study, on production of the required certificates, provided not less than one winter and one summer session have elapsed since the passing in Anatomy and Physiology at the Second Examination.

Candidates will be admissible to Part IV on the completion of four winter and four summer sessions of professional study, on production of the required certificates, provided they have passed in Anatomy and Physiology at the Second Examination.

I. MEDICINE.

1. There will be two papers of five questions each, on the Principles and Practice of Medicine, including Medical Anatomy, Pathology, Therapeutics, Forensic Medicine, and Public Health.

2. Three hours will be allowed for each paper.

3. There will be a Clinical Examination on Patients of thirty minutes' duration, divided between two examiners; after which each candidate will be required to prescribe in writing for a given case or disease, and for this a quarter of an hour will be allowed.

4. The *visu vocis* and practical Examination in Medicine will be the same as at present, and will last twenty minutes.

II. SURGERY.

1. There will be one paper of six questions on the Principles and Practice of Surgery, including Surgical Anatomy and Pathology.

2. Three hours will be allowed for this paper.

3. There will be a Clinical Examination on Patients of thirty minutes' duration, divided between two examiners.

4. The *visu vocis* Examination will consist of three parts:

(a) Surgical Anatomy, Operations, and apparatus of fifteen minutes' duration.

(b) and (c) Principles and Practice of Surgery, including Pathology, each of ten minutes' duration.

5. Candidates will be required to examine microscopical specimens.

III. MIDWIFERY AND DISEASES OF WOMEN.

1. There will be one paper of six questions.

2. Three hours will be allowed for this paper.

3. There will be a *visu vocis* Examination of twenty minutes' duration, divided between two examiners.

This arrangement involves no alteration in the present form of the examination.

IV. PHARMACOLOGY.

1. There will be one paper of six questions.

2. Three hours will be allowed for this paper.

3. There will be no *visu vocis* Examination.

Among the new buildings of the University of Minnesota, which are now nearly completed, are medical laboratories estimated to cost 40,000 dollars (£8,000).

THE CARE OF EPILEPTICS.

THE new home (the Passmore Edwards House) which has recently been erected in connection with the colony of the National Society for the Employment of Epileptics was opened on November 26th by the Duke of Devonshire.

This colony has for some time back been established at Chalfont St. Peter, a village in South Bucks, on a farm given by Mr. Passmore Edwards, and there it is proposed gradually to extend operations, and erect other homes for women and also for children as means allow. The progress already made in the condition of the little group of colonists is stated to be most encouraging, as in fact there is every reason to believe that it will continue to be, for it supplies the epileptic with that which, under ordinary conditions, it is most difficult to find for him—namely, healthy and continuous occupation together with proper care whenever his malady may attack him.

THE DUKE OF DEVONSHIRE, in formally declaring the home open, drew attention to the large number and the pitiable condition of the epileptics in this country. It was estimated that they amounted to between 30,000 and 40,000, a number double as large as that of the blind, and four times as large as that of the deaf and dumb. That some idea might be obtained of the lamentable condition to which persons suffering from epilepsy were reduced, he pointed out the great frequency with which they drifted into the work-house or the union infirmary, not from any fault of their own, but in consequence of the incapacity resulting from their complaint. It was the peculiar misfortune of those who suffered from this affliction to be debarred by the nature of their malady from those modes of life which were most remedial to their condition, from regular occupation and the enjoyment of social and congenial intercourse. All physicians agreed that under proper supervision and favourable conditions there was nothing in this infirmity which need debar those who suffered from it from active and useful occupation. The utility of occupation and employment as a means of treatment had been well established at a similar colony which had been in operation in Germany for the past twenty-six years, where a large number of epileptics were engaged in the active and effective cultivation of a farm of 400 acres, and the same thing had also been shown in England. It was owing to the munificent gift of Mr. Passmore Edwards that the Society had been able to obtain this farm, which was to be the scene of the future colony, and it was largely owing to his assistance that the home which they opened that afternoon had been built, and he could only express the hope that the splendid example set by Mr. Passmore Edwards might be followed by others.

THE RETIREMENT OF PROFESSORS IN THE SCOTTISH UNIVERSITIES.

IN the report of the Treasury Committee on the question of the desirability of a fixed age for the compulsory retirement of professors serving under the Crown, which appeared at page 801 of the BRITISH MEDICAL JOURNAL for September 26th, there were two sentences of reference to the Scottish universities. In view of the development of opinion it may not be amiss to allude further to the subject.

IN Edinburgh and in Glasgow (not merely in Edinburgh as the report stated) extramural teaching practically meets the difficulty. The extramural school of Edinburgh is manned by a large staff of able and accomplished investigators, many of them also excellent teachers. When a professor lags behind the times, or from any cause becomes inefficient, his class diminishes in size, and the best students go to the extramural teacher or teachers in that subject. Until a year ago, when the new arrangement was made by the Universities Commissioners, the loss of students meant diminution of income. That indeed was the only valid argument in favour of professors directly receiving fees from their students. It was of necessity a powerful incentive to work. Then, again, it often happens that teachers in the extramural school are also additional examiners for degrees in medicine. At the present moment, for example, eight of the additional examiners at Edinburgh lecture in their respective subjects

outside the university. The professor and the examiner are thus brought into a kind of friendly rivalry, which tends to fresher and more vigorous work, inasmuch as the extramural teacher if he be also an examiner, attracts a larger audience of university students.

In the Faculty of Medicine of the University of Edinburgh three of the professors are appointed by the Crown, the principal and the other nine professors by the Curators of Patronage (a body composed of seven members, four elected by the Town Council and three by the University Court); all hold office *ad vitam aut culpam*. The principal or professors can only demit office if they be certified medically to be no longer able for the duties of their offices. It has rarely happened that a professor has, either from age or other incapacity, continued to hold his chair when he was unable fitly to do his work, and it has been even more rarely necessary to superannuate a professor because of diminished efficiency through age. Still without doubt it would be a vast improvement on the *ad vitam aut culpam* condition of appointment if a professor could, if he so wished, retire from his chair with full pension rights, say, at the age of 60 or 65, as is suggested in the Parliamentary Report on which we have based our present remarks. Good reason for retirement must be forthcoming, but the University Court might be trusted to narrowly scrutinize this.

Finally it must be admitted that the medical faculty in the various Scottish universities would have been strengthened by the appointment, as in the German universities, of active young "extraordinary professors," who, though not on the ordinary staff of the colleges, would have given competing lectures within their walls. It was indeed expected in some quarters that the Universities Commissioners would have promulgated some such scheme, but in this as in several other matters those who are zealous for the medical prestige and progress of our universities, have thus far been doomed to disappointment.

Thus far, because the Commissioners have applied for and are likely to get a further lease of life for a year from January 1st next, and there will still be time and opportunity to tackle the question of medical education in a statesmanlike way.

ASSOCIATION INTELLIGENCE.

BRANCH MEETINGS TO BE HELD.

BRIDGE AND DISTRICT BRANCH.—A meeting of this Branch will be held in the Anatomy Rooms, University College, London, on Saturday, November 23rd, at 4 P.M., to consider (1) what action, if any, the Branch should take in the matter of medical clubs, etc.; (2) the giving of chloroform for unregistered dentists.—R. G. PEAR, M.D., Anfield House, London.

METROPOLITAN COUNTIES BRANCH (SOUTH LONDON DISTRICT).—The next meeting will be held on Tuesday, December 10th, at 3.30 P.M. at the Lambeth Infirmary, Rotherhithe. Clinical cases will be demonstrated by Dr. QUARRY, Medical Superintendent. All practitioners, whether members of the Association or not, will be heartily welcomed.—H. BETHAM ROBINSON, Honorary Secretary, 1, Upper Wimpole Street, W.

BIRMINGHAM AND MIDLAND COUNTIES BRANCH. The second ordinary meeting of this Branch was held at the Medical Institute on November 14th; Dr. CARTER, President, in the chair. Forty-three members were present.

New Member.—E. P. Satchell, M.B., B.S. Durh., already a member of the Association, was elected a member of the Branch.

Proposed Ethical Committee.—The Council reported that the question of the formation of an Ethical Committee was under consideration, and the minute relative to the same was considered.

[A report of the scientific part of the proceedings will be found at p. 1394.]

SOUTH WALES AND MONMOUTHSHIRE BRANCH. The autumn meeting of this Branch was held, through the kindness of Dr. Pringle, at the County Asylum, Bridgend, on

November 19th. The President (Mr. J. Griffith Lock, of Tenby) having met with an accident, Dr. REDWOOD (President-elect) occupied the chair. There were over thirty members present.

New Members.—The following were elected: Messrs. T. M. Jones Powell, M.B., Swansea; J. J. E. Biggs (Cardiff); F. P. S. Cresswell, M.B., B.S., F.R.C.S., Cardiff; and John Marshall, M.B., C.M., Bridgend.

Vote of Sympathy.—A resolution expressive of sympathy with the President was passed.

Proposed Alteration of Rules.—Mr. E. T. COLLINS (Cardiff) moved the adoption of certain alterations in the rules of the Branch, of which he had given notice. A discussion followed, and in the end the proposed alterations were rejected.

Abuse of Medical Charities.—Mr. GARNETT HODGKIN (Cardiff) read a report drawn up by a Subcommittee appointed to consider the abuse of medical charities in Cardiff. The report was discussed and a vote of thanks accorded. The reports from the Swansea and Newport Subcommittees were not presented.

Communications.—E. LE CRONIER LANCASTER, M.B. (Swansea), showed Microscopic Slides of the Parasite of Quotidian Ague.—Dr. SHENN (Cardiff) showed (1) Large Dense Osteosarcoma involving Lower End of Right Femur, for which amputation had been done in upper third; (2) Papilloma or "Villous Tumour" of Rectum, size of an orange, removed from a male patient, aged 60.—Many papers and specimens were, owing to want of time, reserved for the next meeting.

Visit to Asylum.—The members were shown over the asylum by Dr. Pringle and his assistant medical officers, and a cordial vote of thanks was passed by the meeting.

Dinner.—The dinner at the Wyndham Hotel, Bridgend, in the evening was attended by nearly thirty members and friends.

METROPOLITAN COUNTIES BRANCH: EAST LONDON AND SOUTH ESSEX DISTRICT.

A MEETING of this District was held at Walthamstow on November 21st, Dr. DALY, Vice-President of the District, in the chair. Fourteen members and five visitors were present.

Confirmation of Minutes.—The minutes of the previous meeting were read and confirmed.

Communication.—Mr. BOWLEY read a paper on Diseases of the Throat and Nose in Childhood. He dealt with discharges from the nose, foreign bodies in the nose, atrophic rhinitis, enlarged turbinate bodies, adenoids and hypertrophied tonsils, with the causes, symptoms, and appropriate treatment in each case. In the discussion which followed, the CHAIRMAN, Drs. SHADWELL, WALKER, WARNER, and the HONORARY SECRETARY took part.

Vote of Thanks.—At the close of the meeting a hearty vote of thanks to Mr. Bowley for his instructive and interesting paper was carried unanimously.

SPECIAL CORRESPONDENCE.

PARIS.

The District System of Hospital Organisation.—Sanitation in Match Factories.—A Female Medical Practitioner at Montreal.—Professor Tillaur.—Foreign Students in Paris.—General News.

DR. A. BROCA, son of the celebrated surgeon of that name, has publicly expressed his opinion that the hospital outdoor department requires reform. The Municipal Council ratifies the argument of the hospital physicians and surgeons that it is inhuman not to allow the poor to choose their own medical adviser. M. Dubois asks if they were able to do so under the old régime, when they went to the outpatient department, and were seen by an ordinary student, or sent from one hospital to another. The *Progrès Médical* endorses this view, and medical students, if they had a voice in the matter, could do so likewise. The *circumscriptions hospitalières* will probably be maintained with some modifications. M. Peyron stated at the last meeting of the Municipal Council that he is willing to make all the improvements experience may show to be necessary.

The Minister of Finance has visited the Pantin and Aubervilliers lucifer match factories, and has conscientiously inspected the different workshops. He is said to have declared that they are hotbeds of infection into which he would not put prisoners sentenced to penal servitude. He afterwards received the Federal Council of the lucifer match hands. There was no question of increased wages; the conditions in which the hands work were solely considered. A yearly allowance of three blue linen suits was asked for for factory use; lifts and cranes for lifting and removing heavy weights, and better sanitation were also demanded. The Minister promised to carry out these reforms and to suppress the use of white phosphorus, and to have it replaced by amorphous phosphorus and other chemical products if they are recognized to be suitable. May his ministerial life be long enough for him to allow him to give effect to his good intentions!

The medical men at Montreuil-sous-Bois have refused to see out-patients at the dispensary recently organised there by the Mayor, because Mme. Bertillon, an M.D. of Paris, was asked to join the staff of the dispensary. M. Garaud, the senior of the Montreuil practitioners, has been interviewed, and states that the medical men in question give their services without fee, and that they are at a loss to understand why the communal budget should be charged with an expenditure of £60 to remunerate Mme. Bertillon for her dispensary consultation.

The banquet given in honour of Professor Tillaux on the occasion of his nomination to be a Knight of the Legion of Honour was an agreeable contrast to the usual run of festivities of this kind. Professor Tillaux was for twenty-five years Lecturer on Anatomy at Clamart. This fundamental part of medical teaching was entirely neglected at the Medical Faculty; Professor Tillaux, without any substantial remuneration, and contenting himself with the grateful appreciation of his pupils, positively inaugurated a new era in the teaching of anatomy. Before attaining the position of Clinical Professor, which was delayed by the opposition of a small but powerful clique, Professor Tillaux had done the work of half a dozen ordinary professors. He is now recognised as one of the best teachers of clinical surgery in Paris.

The statements recently made in some English daily papers that foreign students are allowed to pass their examinations in the Paris faculties with the help of interpreters is entirely incorrect. There is, however, among all students a feeling that their foreign comrades are more tenderly treated than themselves, and they explain the indulgence of their examiners by their indifference whether the foreign students are well versed in the subject of their studies or not because they will go elsewhere to practise their profession.

A fire broke out at the Pau Hospital; fortunately the patients were able to be removed. An entire storey of the new part of the building has been destroyed.

Mme. Juliette Dodu, Chevalier de la Légion d'Honneur, offers to the Paris Academy of Sciences the library of her late godfather, Baron Larrey, likewise his portrait painted by Gignoux.

VIENNA..

The General Hospital.—Professor Albert and the Medical Education of Women.—General Paralysis and Syphilis.—The Viennese Medical Chamber.

This year's session finds the large old hospital in no better state, though last year various projects arose for enlarging the clinics or transferring them to new and spacious buildings to be erected and well fitted with all the apparatus of modern medical science so conspicuous by its absence in the old house. The most promising proposal was the project of Professor Max Gruber to use the vast area of the lunatic asylum (which was to be transferred to some remoter part of the environs) for the building of new clinical institutes; it failed, as did most of the others, owing to financial difficulties. Public interest in Vienna is given up to political agitation, and the faculty is perhaps as far as ever from obtaining an adequate home. In Professor Schauta's gynaecological clinic some urgent improvements have been made.

Great sensation has been caused by Professor Albert's recent essay on Women and the Study of Medicine. Not only in the

columns of the lay press but in general conversation and at numerous meetings held to discuss it, the question is debated over and over again. Especially the fair writers and speakers are thundering most alarmingly against the learned critic of their sex, and the eminent surgeon, who desired for women in general the liberty to study medicine, seems to have gained far more rebuke than fame. He is said, however, to be preparing another extensive work on the same subject, in which he will come down upon his adversaries with heavier statistical and philosophical arguments.

In a paper read at the last meeting of the "Psychiatric Club" in Prague Dr. Hirschl, one of Kraft-Ebing's assistants, argues that paralysis of the insane is a manifestation of the third stage of syphilis. In the reports of 20 cases he finds the other etiological factors hitherto accepted wholly insignificant; on the contrary, syphilis had preceded in a larger percentage of cases than even in patients attending Professor Lang's clinic suffering from gummatus processes in different parts of the body. As to the inefficaciousness of antisyphilitic treatment, Dr. Hirschl points out gummata can only be replaced by cicatricial tissue. A man with post-gummatous scars on his arm may still be looked at as generally healthy; defects in his brain cortex, though filled up by connective tissue, make him paralytic in a remission. Hirschl sees nothing in microscopical changes that could not be taken as an effect of syphilis, the whole affection being, then, one of encephalitis syphilitica, ending in atrophica cerebro-syphilitica.

The new institution of "medical chambers" does not as yet enjoy the general interest and sympathy to which an official Board destined for the regulation and preservation of the profession's interests should seem to be entitled. Not much of real good has yet been done by these chambers, and many, noting the unsuccessful schemes of the chamber, feel keenly at the same time the hardship of the tribute it lays on them, and resent both.

FLORENCE.

An Early Physiological Institute.—Cremation in Florence.—General News.

THE academical year of the Florence University was opened on November 4th with an inaugural address by Signor Giulio Fano, Professor of Physiology, who reminded his audience that a school of biological research had been inaugurated by Cardinal Leopold dei Medici in 1657 under the name of "Accademia del Cimento" (experiment). Its members were chiefly engaged in physical research work, and their motto—"Provare e riprovare" (to test and test again)—is still retained by the Florence School of Physiology. After ten years of active work, this institution was suppressed in deference to ecclesiastical scruples.

On November 10th, the body of Baron Philip de Lopes Netto, ex-Minister of Brazil, was cremated. The ashes were consigned with the required formalities to the Marchese Luigi Nicolini, President of the Society for the Cremation of Bodies in Florence. This Society is one of fifty-two similar associations at the present time existing in Italy. It was incorporated by statute in the year 1882. The first cremation was conducted in April, 1885, and altogether the Society has cremated 214 bodies. The number of cremations performed during the last corporate year amounted to 31. The Society, which is non-sectarian, consists at present of 547 members, including the customary officers. The sum of 50 lire (francs), payable either in one sum or by monthly instalments of 5 lire, entitles the subscriber to the privileges of membership; to attend and vote at all general meetings of the Society; and in case of death the members are entitled to cremation free of all charge other than the regular taxes and municipal charges. This renders cremation more economical than ordinary burial. Membership is strictly personal, and its privileges are not transferable.

By a recent decree of the Legislature, Drs. Gabbi and Morianelli, late assistants of Professors Graeco and Pellizzari respectively, have been appointed to professorial chairs, the one at the University of Messina, the other at that of Modena. The appointment of the two young professors was the occasion of a banquet given by their colleagues of the Florence University to commemorate the event.

Professor De Renzi, of Naples, has announced the production in his laboratory of an antipneumonic lymph. The results of the experiment are described as highly promising.

CORRESPONDENCE.

THE BATTLE OF THE CLUBS.

SIR.—The Kidderminster and District Medical Society have appointed a small committee to inquire into the abuses of medical aid associations and clubs, which exist and flourish in this district, to the great injury of the medical practitioners. I should be very much obliged for any information from other medical societies as to any action that may have been taken with regard to the above question, with result up to the present time, and also as to the rules framed for the guidance of their members in the matter of dealing with medical aid associations and clubs. Our great difficulty here is that if we attempt to deal with the large friendly societies they will go over in a body to the two medical aid associations which are formed here, and so strengthen them. These medical aid associations have already, to a great extent, been boycotted (the officers included), though Birmingham and Worcester consultants continue to meet the medical officers and thereby to a certain degree countenance and help the associations.—I am, etc.,

W. MOORE,

President of the Kidderminster and District Medical Society.

Stourport, Nov. 25th.

SIR.—Ever since the dispute between the medical men and clubs in Cork I have followed the matter very carefully. The general opinion expressed is, that the profession have it in their own hands to stop the abuse by combination, but I do not think that the profession ever will combine under existing circumstances.

I have a practice in an agricultural and mining district; my income is between £700 and £800 a year, of which I am paid by clubs £350, midwifery and vaccination £100, about £100 by families of colliers who prefer to pay me privately instead of going into the village sick club; the remainder I am paid by farmers, shopkeepers, etc. There is another medical man who is paid by the colliery class one way and another about £250 a year, which makes say £600 paid every year to myself and another from the colliery and labouring class by clubs, for confinements, etc., by club members. Now, were a medical aid society started here, and a salary of £500 a year offered, with midwifery fees, how many applicants would there be for the appointment? Who could blame the referees of assistants applying? Would they not be very much better off making £500 a year among the same class of people than being paid £150 by another practitioner?

I think, however, with time and money, we could deliver ourselves. My suggestion is that every practitioner should subscribe to a fund, appoint a secretary, whose business would be to see every doctor in the country, form certain rules, in no way harsh to the poorer class, but such as must secure a fair payment from clubs; then, when we had agreed on what we considered just, to bring pressure on the influential men in the different towns, who would in their turn bring pressure on the proper authorities to make it infamous practice for any man to work for less than the minimum amount agreed upon.

I consider it would take an income of £2,000 a year for five or six years to bring such a scheme to a successful conclusion, but feel confident such an amount could easily be raised. It would be for the benefit of all medical men to have a minimum fixed by law, and it would not make it any more difficult for a man to start practice than before, but would prevent him from underselling every man in his neighbourhood.

I am quite willing to pay an annual subscription for such a purpose if the idea is taken up, but I certainly will not do anything individually to lose the practice I have now.—I am, etc.,

November 25th.

CLUB DOCTOR.

INVITATION FOR TENDERS WITHDRAWN.

SIR.—My attention having been drawn to a paragraph in the BRITISH MEDICAL JOURNAL adversely criticising my circular to the medical profession in Blackpool, I beg to withdraw my offer for tenders, and to express my regret that I have unknowingly asked medical gentlemen to do something which might be deemed to be departing from the honourable traditions of the profession. At some convenient time I will ask a gentleman to take the post of visiting physician to the Hydropathic.—I am, etc.,

Blackpool, Nov. 2nd.

SAMUEL HORROCKS.

THE BRITISH MEDICAL BENEVOLENT FUND.

SIR.—I am happy to say that we have been able to make grants amounting to £161 at the meeting of the Committee to-day, and I have still to acknowledge with very grateful thanks the following donations:

£ s. d.		£ s. d.	
Mr. Edmund Owen...	2 2 0	Mr. Brook	0 10 6
Dr. Travers	5 5 0	Mr. Wilfred Thomas	0 10 6
Mr. John King (per Dr. Travers)	50 0 0		

I am, etc.,

Brook Street, W., Nov. 25th.

W. H. BROADBENT.

THE GUILD OF ST. LUKE.

SIR.—November 30th, St. Andrew's Day, is set apart for "special intercession for missions." May I, as Provost of the Guild of St. Luke, draw attention to the demand now existing for medical missionaries? Of these about sixty are employed by the Church of England Missionary Societies, of whom a third are our associates. Several colonial bishops, also members of the Guild, are urgently needing helpers. The Bishop of Bloemfontein, himself a Fellow of the Royal College of Physicians, is now acting for a medical missionary; so is the Archdeacon of Mashonaland. The Universities' Mission to Central Africa, and the Chota-Nagpur Mission in India also crave help.

The salaries offered vary from £100 to £300 a year. The stations in which they are needed are not always unhealthy, although the demand is naturally greater where disease is most rife. The call "to heal the sick" is as incumbent upon us as to "preach the Gospel" throughout the world. May we not hope that volunteers will come forward for this work?

Men possessing knowledge of medical sanitation and tropical hygiene are specially needed. If our missionary societies could secure the services of one imbued with the spirit and the knowledge of Edmund Parkes, who would see that the mission stations were free from every removable source of danger, and who would select sites for new stations and arrange hospital accommodation for sick natives and convalescent missionaries, many valuable lives annually sacrificed would be preserved.

His Grace the Archbishop of Canterbury has promised to preach for the Guild next year. Every loyal Churchman in the profession should be stirred to do what in him lies to promote the good cause we have at heart.—I am, etc.,

E. SYMES THOMPSON, M.D., F.R.C.P.

Cavendish Square, W., Nov. 25th. Provost of the Guild of St. Luke.

VACCINATION WITH STORED LYMPH.

SIR.—I have no doubt that many of your readers, like myself, have often found vaccine lymph stored in capillary tubes to fall in its effect. I believe the reason of such failure to be this—that when very fine tubes are used and are well filled the heat employed in sealing the ends is contained along the tubes, and so sterilises the lymph wholly or in part. Whereas, if the tubes were of larger bore and stouter, and contained less lymph, the sealing might be effected without injury to their contents.

As an illustration of the above, I lately obtained two tubes of humanised lymph from the Local Government Board, with which I vaccinated nine children. Half the punctures totally failed, so that I had to vaccinate some of them again; and I attribute it to the fineness of the tubes and to their being filled nearly to the ends.

As lymph so stored must often lead to similar results, we can understand the Board's rooted dislike to anything but arm-to-arm vaccination. At the same time the failure of

stored lymph may often be set down to the defective method of storage adopted by the Department rather than to the system itself.—I am, etc.,

Guildford, Nov. 15th.

HENRY TAYLOR.

* It may be doubted whether the object desired could be secured by the use of lymph tubes of larger bore and thicker glass than those now and for some time adopted by the Local Government Board. The sealing by heat—now such a simple matter, and effected without the destruction of the tube—would be more difficult if larger and thicker tubes were used. It is unnecessary, in the majority of instances, to vaccinate so many as nine children with stored lymph, since the lymph sent out in a stored condition by the Local Government Board is intended only for the one purpose of starting a series of cases which shall enable vaccinators to continue from them a constant supply of human lymph from arm to arm, and thus obviate the many objections to any but absolutely fresh lymph. If human stored lymph be deemed unsatisfactory as a means of starting a series of arm-to-arm vaccinations, there is the alternative of stored calf lymph on points; but, whilst the objection of tubes is set aside in this case, we doubt whether the risk of failure is not greater. After all the amount of failure of stored lymph in the hands of a skilful vaccinator, such as our correspondent is, will not be large, and the arm of a selected vaccinifer having been successfully operated upon, the need for resort to stored lymph will not be great.

DIPHTHERIA ANTITOXIN AS A CULTURE MEDIUM FOR THE DIPHTHERIA BACILLUS.

SIR,—In the correspondence on this subject which has already appeared in the columns of the *BRITISH MEDICAL JOURNAL* some of the writers undoubtedly think that I am opposed to the antitoxin treatment of diphtheria. I can assure them that is not the case. Professor Wright, I am sorry to find, assumes from my letter of November 9th that I wished to impale Dr. Semple and himself upon the horns of a dilemma. If he refers to the paragraph in question he will perceive that the so-called dilemma is a personal one, and refers only to myself. However that may be, Dr. Wright readily extricates himself to his own satisfaction, and in so doing propounds a series of dual propositions, which are here reproduced in parallel columns:

- | | |
|---|--|
| 1. Alcohol is produced by the yeast plant. | 1. Diphtheria toxin is produced by the diphtheria bacillus. |
| 2. The absorption of alcohol into the system constitutes "alcoholic intoxication." | 2. The absorption of diphtheria toxin into the system constitutes "diphtheria intoxication." |
| 3. Certain drugs, such as opium or bromide of potassium, do to some extent neutralise the effects of that alcoholic intoxication. | 3. Diphtheria antitoxins neutralise the effects of that diphtheria toxin. |
| 4. Sugar solution constitutes an excellent culture medium for the yeast plant. | 4. Serum is a good culture medium for the diphtheria bacillus. |

Now, it is easy to follow the chain of reasoning through the first three propositions in each column, although some of the included statements may be questionable; but at the end of each of the third paragraphs the proverbial red herring is drawn across the scent by making two *trite* observations which no one is likely to dispute. If, in the fourth propositions, instead of the words in italics, "a solution of opium" and "diphtheria antitoxin" were respectively substituted, the context would be more logical if less convincing.

Another of your correspondents, whilst fully confirming Dr. Wright's experiment, suggests that the heat required to coagulate the antitoxin destroys its bactericidal properties. If that is so, diphtheria bacilli ought to die when floated on fresh antitoxin and kept at a body temperature. On the contrary, I am afraid that the microbes would not only survive this treatment but thrive upon it. However, this is a question which a simple experiment would at once settle.

Yet another gentleman considers that we must look to Metchnikoff's theory for the true explanation of the action of antitoxin; that this product when introduced into the

body stimulates "the living phagocytic cells." Now, if this explains the remedial process, antitoxin must act either as a general stimulant or as a special stimulant. If it acts as a general stimulant to the phagocytes throughout the body, I cannot see in what way diphtheria antitoxin differs in its action from half a score of other remedies, such as quinine or iron, which have at various times been credited with similar qualities. If, on the other hand, it is a special stimulant, and prompts these little bodies to devour only *Klebs-Loeffler bacilli* and their antitoxins, many will consider that we are asked to mentally assimilate not only Metchnikoff's theory, but "rudis indigestaque moles" besides.—I am, etc.,

Brighton, Nov. 25th.

W. AINSLIE HOLLIS.

THE GENERAL MEDICAL COUNCIL AND DIRECT REPRESENTATION.

SIR,—In these days of direct representation it is difficult to understand why we should be satisfied with the method of election of the members of the General Medical Council. Since it will be necessary to go to Parliament on the subject, it seems to me that we had better take the bull by the horns and endeavour to get direct representation *in toto*. If it is necessary that each qualifying body should send a representative, by all manner of means let it do so, but let these representatives be elected by the votes of the graduates or members of the different bodies. In this way each corporation would be represented, and yet the Council would be elected by us, who find all the funds. This seems to be the only satisfactory way of settling the question once for all.—I am, etc.,

Banbury, Nov. 25th.

JAMES GRIFFIN, M.R.C.S., L.S.A.

THE ADMISSION OF WOMEN TO THE EXAMINATIONS OF THE CONJOINT BOARD.

SIR,—I fear that Sir Joseph Fayrer's statement in the course of the debate at the Royal College of Physicians on the admission of women to the Licentiate'ship, that "he had never known any instance where in a case of serious illness any difficulty had been placed in the way of a physician or surgeon entering a harem, and if he found it necessary the patient was always uncovered," may, quite unintentionally, give too favourable an impression of the degree to which Indian women have access to skilled medical advice. His experience is just what we should expect. The English doctor hears only of such women as are permitted or will consent to see him; of the many who by strong social custom are prevented from seeing him or any other male physician or surgeon he does not hear. Probably more Indian women are treated by medical men at the present day than was the case twenty years ago. But as a qualified medical woman who has had five years' practice in India I can say that two years ago it was an every-day occurrence in Calcutta to call in a medical man to diagnose and treat the illness of a patient whom he either did not see at all, or on whom he was not permitted to carry out a physical examination. At the present day it is very much the custom to call in a medical woman at the same time in consultation, who is free to see and examine the patient. Formerly the doctor had the assistance of a midwife, trained or untrained, upon whose information his diagnosis had mainly to rest.—I am, etc.,

November 23rd.

MEDICA.

FEMALE MEMBERSHIP OF CLUBS.

SIR,—Various country newspapers containing reports of meetings of friendly societies mention the intention (carried into effect by the Foresters in at least one town) to admit women as members. I suppose the medical profession, as ratepayers and philanthropists, will welcome and support any movement to increase the wellbeing and thriftiness of our working classes, but when their women co-operate, and wish to obtain medical, gynecological, and surgical attendance, and medicines from our already far-too-much-inflated profession for a very few shillings a year each, it behoves us also to co-operate, and strenuously decline to be "swamped" any more than we have already weakly permitted ourselves to be by the men (many of whom do not belong to the working class and can well afford moderate fees) and boys by co-

lamentable want of union and *esprit de corps*. If medical practitioners would "strike" by resisting these attempts to lessen their professional position and incomes, and copy the excellent examples set by their brethren of Cork, Portsmouth, and Malvern they would win. The public cannot do without our aid; why should we, practically, give it? Why should we foolishly impoverish ourselves and our families and receive no thanks but contempt by consenting to most inadequate acknowledgment of our services? Truly the prospects of our young practitioners are most deplorable and regrettable unless we improve our position, as it is in our power to do.—I am, etc.,

November 23rd.

A STRUGGLING PRACTITIONER.

INFLUENZA: WANTED A DEFINITION.

SIR.—The following definition represents fairly accurately the way in which the term influenza is at present applied: "Influenza is a name given to every case of illness in any district in which the newspapers say that influenza is prevalent."

Among medical men there are at least two diseases—diseases as different as scarlatina and measles—classed under the head of influenza:

1. Russian influenza, which became epidemic in 1889-90, characterised by sudden invasion, often rigors, high temperature, great pains in the back, limbs, and head, and no catarrhal symptoms; it affects chiefly adults, convalescence being marked by subnormal temperature and great prostration, its chief complication, when one occurs, being lobar pneumonia.

2. Catarrh; invasion not so sudden, temperature not high to start with, catarrhal symptoms (running at the nose, cough, etc.) being present from the very first—complication, broncho-pneumonia.

We have always had one or two cases a year of No. 1, called by the common people a "thorough cold," but until 1889 they did not appear to be infectious, and now when we have cases in country practice it is almost impossible to trace the sources of infection, and the cases do not appear to breed other cases like them.

No. 2 has always been prevalent, and always looked upon as infectious. There is an old saying, "If the cat has a cold it runs through the house." But since No. 1 has been prevalent, the cases of No. 2 are followed by more depression than formerly.

Bacteriologists do not appear to have helped us much in our study of influenza, for Koch's four postulates have not yet been satisfied, as far as I can learn from studying the *BRITISH MEDICAL JOURNAL*, but the tubercle bacillus has taught us that the soil and environment are as important factors in the production of phthisis as the seed itself, and one of the old theories of influenza is possibly true—that influenza is not a specific disease, but is a climatic influence producing an intensification of the toxic power of some microbes which are commonly and universally present.—I am, etc.,

Bristol, Nov. 22nd.

GEORGE BIR, M.B.Lond.

ANTISEPTICS IN FOODS.

SIR.—In the *BRITISH MEDICAL JOURNAL* of November 16th there is under the heading "Antiseptics in Foods" an editorial note suggesting that the recent prosecution for selling orange wine containing salicylic acid raises a question as to the propriety of preserving foods by antiseptics.

Without disputing the opinion there expressed that this question is a matter for discussion, I wish to protest against some of the statements put forward as showing that the use of salicylic acid for the preservation of articles of food is injurious to health. There is, in the first place, no foundation for the statement that "salicylic acid is a poison;" and, secondly, the cases referred to, in which it is alleged that salicylic acid has produced injury, are altogether different from the case of the orange wine in question, the quantity administered in those cases having been from 135 to 2,000 times as much as the quantity of salicylic acid that would be taken in a glass of the orange wine, that being, moreover, only one-fiftieth part of the average medicinal dose.

Conclusions drawn from such cases, and from the un-

warranted assumption that salicylic acid is poisonous, cannot be of any value in regard to the use of salicylic acid in minute proportion for the preservation of articles of food, though they might tend to prejudice the settlement of the real questions at issue in the case still pending—namely, whether the small proportion of salicylic acid used for the purpose of preservation is, or is not, injurious to health, and whether the sale of such an article is to be regarded as an infringement of Section 6 of Food and Drugs Act, or as one of the exempted cases therein provided for.—I am, etc.,

Fenchurch Avenue, E.C., Nov. 23rd.

BESS. H. PAUL.

THE MARCHING POWERS OF OUR SOLDIERS.

SIR.—How Surgeon-Major F. P. Nichols, A.M.S., can possibly describe the ammunition boot, price 9s. 2d., which has been served out to the line and the militia as an excellent boot is beyond me. The waist of this boot is almost as stiff and unbending as a bar of iron. It has a clump sole; the inner edge is curved, so that it makes the scaphoid bone protrude, and cruelly lames the men. As to drying these boots in one night in camp, I can only say that it takes a valet two days to dry a pair of wet shooting boots. Dressing the boots with an oil brush with a mixture of neats' foot oil and castor-oil is far the most expeditious way of softening the leather.

As the Adjutant-General is said to approve the pattern of this boot, I hope public opinion, and the medical profession in particular, will continue to point out to this officer the unfortunate selection he has made.

For the benefit of the Aldershot staff I may point out that the waist and tread are hardly synonymous terms. The clump sole is the tread, and this crimps the foot.—I am, etc.,

W. H. ALLSOPP,
Lieutenant Colonel.

Pall Mall, S.W., Nov. 23rd.

THE CLEANING AND DEODORISATION OF CATHETERS.

SIR.—"There is nothing new under the sun." In the *Lancet* in 1883 I described a catheter made for me by Messrs. Young, of Edinburgh, with a solid end beyond the eye, and carefully bevelled off opposite the eye. These were of silver; and the next year Messrs. Maw, Son, and Thompson made for me silk web catheters of similar construction. These they now sell, and I believe my name is appended to them.

On this ground I venture to take slight exception to the letter of Dr. J. Ward Cousins, in which he says: "I again desire to accentuate the importance of manufacturing all catheters with solid points." He has invented so many useful surgical instruments that he can well afford to leave me in possession of this one little source of satisfaction.—I am, etc.,

A. OCHER WARD.

Tottenham, Nov. 26th.

THE SCHOTT TREATMENT OF HEART DISEASE.

SIR.—During last summer I spent nearly five weeks at Naheim Bad, and I had almost daily opportunities of seeing the Schott treatment carried out. Unfortunately there is no hospital at Naheim, and the treatment must be watched in private patients. We all know how much this increases the difficulty of careful study and investigation. Nevertheless, thanks to Dr. Schott and Professor Heinemann, I was able to follow several cases rather closely, and I left Naheim convinced that the value of the treatment was beyond all controversy.

As to the duration of the cure or improvement I heard of many instances in which it had lasted several years, and since my return to England I have seen two cases of dilatation, one without and one with valvular mischief, and both have maintained their improvement from July or August to the present time.

While fully endorsing what has been said of the good results of the treatment, I am not sure I should like to accept any of the explanations yet given, and I think many important questions present themselves for solution by the physiologist and pathologist. In the meantime clinical facts far outweigh either objections or explanations, and while the whole profession is indebted to Dr. Schott for discovering the value of the treatment, that of England is scarcely less indebted to Dr. Bealy Thorne for making it known here.

In some of the cases I saw at Naheim the diminution of

the dilated heart was so marked that it was difficult to believe it. Probably, however, the real diminution is less than the apparent. A transverse section of the thorax would show both heart and chest wall of circular outline, hence lines drawn from the side limits of the area of cardiac dulness towards the heart would tend to approximate, just as would lines drawn from the tire of a wheel to the hub, although, of course, to a far greater extent than in the case of the heart. This fact would explain something. It has, however, very little bearing on the diminution of the top limit of dulness, but then this diminution is never, so far as my experience goes, so great as the transverse, nor is the vertical outline of the chest wall so circular as that of the transverse outline.—
I am, etc.,
RICHARD GREENE.

Northampton, Nov. 23rd.

THE PROPOSED GENERAL HOSPITAL FOR CAMBERWELL.

SIR.—The letter which appeared in the *BRITISH MEDICAL JOURNAL* of November 23rd under the above heading, signed by nine medical gentlemen attached to the provident dispensary in Camberwell, having come under my notice, I beg you will kindly allow me a small portion of your valuable space to reply to it.

I will preface my remarks by saying that the proposed general hospital is not designed for Camberwell alone, but for South London. It will, I think, be a matter of deep regret to all who have read the letter I am referring to that these gentlemen should combine in the invidious task of opposing a philanthropic scheme for the alleviation of the suffering and misery of large numbers of their poorer fellow-citizens. That they should support their opposition by a series of misstatements detracts moreover from the significance of their openly avowed hostility to the establishment of a new general hospital for South London.

The meeting held in Camberwell Vestry Hall, to which they so slightly allude, was a public meeting duly convened by public placards—I enclose one that you, Sir, may see it—and at that meeting, at which several members of the vestry were present, the following resolution was carried unanimously:

That having regard to the grievous want of a general hospital for South London, this meeting of residents in and about Camberwell is of opinion that early steps should be taken to establish such an institution.

The nine medical gentlemen who protest against the establishment of a general hospital are, of course, perfectly entitled to their opinion. That it is of sufficient weight to influence the public is, however, quite another matter; and against their opinion I would put the somewhat weightier and more valuable opinion of the Select Committee of the House of Lords, which was appointed "to consider the evidence taken during the sessions of 1890 and 1891 with regard to the hospitals and provident and other public dispensaries and charitable institutions within the metropolitan area." That Committee, with a full knowledge of the medical wants of South London, and aware also of the existence and work of the provident dispensary to which these nine medical gentlemen belong, reported to the House of Lords as follows:

"The Committee would strongly advise that more hospital accommodation should be provided South of the Thames, and were it possible to find the site, and were philanthropic endeavours to be made for further accommodation for the sick in London, a large general hospital (say) in the densely populated district of Camberwell would no doubt be of extreme value."

"The Committee are convinced that more hospital accommodation is required South of the Thames."

I venture to think that the general public will attach very much greater weight to those strongly-expressed opinions of the Select Committee of the House of Lords, formed after a long and most searching inquiry, than it will to the opinion of the nine medical gentlemen who have availed themselves of the publicity afforded by your columns to publicly oppose the movement for the establishment of such a widely beneficial institution as a general hospital.—I am, etc.,
HENRY JEPSON.

Cornwall Gardens, S.W., Nov. 18th.

¹ See report in the *South London Press* of June 2nd, 1895.

OBITUARY.

DR. HENRY COUTAGNE, of Lyons, who has died at the age of 48, was distinguished both in medicine and in music. In his childhood he was hailed as a musical prodigy, and at the age of 8 he was already much in request as a pianist at amateur concerts. He studied medicine at Lyons, and took his degree in Paris in 1871. When the Lyons School was transformed into a Medical Faculty, Coutagne was appointed lecturer on forensic medicine, and he held an official position in connection with the law courts as a medico-legal expert. He translated Taylor's great work, and afterwards published a work of his own on forensic medicine, besides contributing largely to the *Archives d'Anthropologie Criminelle* and the *Lyons Medical*. He found time, also, to indulge his passion for music, and he earned a considerable reputation as a composer. He embodied the impressions of a trip to Denmark, Sweden, and Norway in his *Voyage aux Pays Scandinaves*, and he was also the author of an interesting book entitled *Les Anciens Luthiers de Lyon*.

DEATHS IN THE PROFESSION ABROAD.—Among the members of the medical profession in foreign countries who have recently died are: Professor W. N. Popoff, Lecturer on Physiology in the University of Dorpat; and Dr. Mannel Bertis, sometime Professor of Pathology in the Medical Faculty of San Salvador.

SURGEON-MAJOR GEORGE EDWARD DOBSON died on November 26th. He was the eldest son of the late Mr. Parke Dobson, of Killinagh, co. Westmeath. He was educated at Trinity College, Dublin, where he graduated B.A. in 1866, M.B. and M.Ch. in 1867, and M.A. in 1875. He was First Senior Moderator and First Gold Medallist in Experimental and Natural Science, Classical Honourman and Stearnes Exhibitioner, and a Member of the Senate of the University of Dublin. He entered the Army in 1868, retiring in 1888 with the rank of Surgeon-Major. His *Essay on the Diagnosis and Pathology of the Injuries and Diseases of the Shoulder-Joint* was awarded the gold medal of the Dublin Pathological Society in 1867. He also wrote *Medical Hints to Travellers*, published by the Royal Geographical Society, which reached a sixth edition in 1899. He was F.R.S., F.L.S., F.Z.S., and a Corresponding Member of the Academy of Natural Sciences of Philadelphia and of the Biological Society of Washington.

NAVAL AND MILITARY MEDICAL SERVICES.

THE EXAMINATIONS FOR THE MEDICAL SERVICES: SUCCESSSES AND FAILURES.

It appears from the table furnished to the General Medical Council that at the examination last August for commissions in the Army Medical Staff 23 candidates offered themselves for the 13 appointments; 10 only obtained the qualifying aggregate of marks, though 4 others "qualified, but their total marks did not reach the aggregate required." Of the 9 candidates rejected, 3 failed in all the subjects of examination, 1 in medicine only, 1 in surgery only, 2 in chemistry and pharmacy only, 1 in medicine and chemistry and pharmacy, 1 in anatomy and physiology and chemistry and pharmacy. At the examination for the medical department of the Royal Navy there were 22 candidates and 12 commissions were given, but 17 candidates altogether were found qualified; 3 of the unsuccessful candidates failed in four subjects, and the remaining 2 candidates in three.

At the examination for commissions in the Indian Medical Service in February, 1895, there were 33 competitors for 18 vacancies; 24 qualified altogether, and 9 were rejected. Of these 9, no fewer than 7 failed in medicine (3 of them in that subject only). In the examination for the same service held in August, 1895, there were 37 candidates for 18 vacancies; 22 qualified altogether, 11 failed to obtain half the compulsory marks, and 4 failed in one or more subjects.

It will be seen that the subject of examination in which there was the largest number of failures was chemistry and pharmacy (18), medicine comes next (14), anatomy and physiology next (9), and that the subject in which there was the smallest number of rejections was surgery (8). The same candidate may, of course, appear under more than one qualifying body. Thus 3 of the successful candidates from the Apothecaries' Society had other qualifications.

For the Indian Medical Service there were 10 candidates who were declared qualified, but for whom there were no vacancies.

The subjoined table has been compiled from these returns.

	No. of Candidates.	Successful or Qualified.		Passed for First Marks	Failures in Medicine.	Failures in Surgery.	Failures in Anatomy & Physiology.	Failures in Chemistry & Pharmacy.
		No.	Per cent.

SURGEON-MAJOR-GENERALS.

WE understand that principal medical officers of this rank will now be definitely appointed to stations for at least three years. This is considered to be a step in the right direction, and will do much to remove the complaints of the military authorities as to the constant movement of principal medical officers. As officers on promotion will take up the duties of the station where the vacancy occurs, the consequence will be that some surgeon-major generals will have all their service in the rank at home and others abroad. The new system does not extend to principal medical officers of the rank of surgeon-colonel.

THE NAVY.

SUMNER-COLONEL M. E. P. TINDALL has been placed on the Retired List, receiving a gratuity in lieu of retired pay, October 25th. He was appointed Surgeon, February 11th, 1861.

The following qualified candidates have been appointed Surgeons,
 1st Regt. N.Y. Cavalry: CHARLES H. J. ROBINSON, HAROLD HUCKINSON, M.B.,
 ERNEST S. TUCK, HAROLD G. T. MAJOR, MORRAY P. JONES, ARTHUR W. B.
 LIVESAY, M.B., HERBERT H. GILL, M.B., WILLIAM D. ADAMS, M.A., M.D.,
 WILLIAM E. TITTHALL, JOHN C. HOWAN, M.B., RICHARD A. ROSS, M.B.,
 MICHAEL J. SMITH, B.A., M.D.

The following appointments have been made at the Admiralty:—JOHN DOWSON, Surgeon to the *Basilisk*, December 10th; WILLIAM G. STOTT, M.A., M.D., Surgeon to the *Victory*, additional, for the Duke of Wellington,

ERRATUM.—In the BRITISH MEDICAL JOURNAL of November 23rd we gave the first commission of Deputy-Inspector-General KILL as bearing date March 8th, 1867. We are asked to say that it should have been July 1st, 1864.

ARMY MEDICAL STAFF.

[illegible]

Surgeon General H. T. Sargent, V.C., C.B., retired pay, is also appointed Honorary Surgeon to the Queen and Sir John Kerr, K.C., F.R.C.S., C.B., retired pay, deceased. Surgeon General Sargent entered the Army in 1880, and retired therefrom on the last day of 1901. He served in medical charge of the 61st Regiment at the siege of Boerla from July 1st, 1901, to the

Final capture of the city on September 26th. was present at the repulse of the surface of July 28th, 29th, 30th, and 31st, accompanied the regiment at the assault of the city on September 10th, and 11th, and on the 12th, 13th, 14th, 15th, 16th, 17th, 18th, 19th, 20th, 21st, 22nd, 23rd, 24th, 25th, 26th, 27th, 28th, 29th, 30th, and 31st. He was present at the first up the bank at the assault on September 10th, and 11th, and was a sergeant and a gun team leader in the assault, and recommended for promotion for "unwearied endurance and great courage in the assault during the siege and assault of Fort Mifflin, with duty and valorous conduct."

Surgeon-Lieutenant-Colonel M. D. O'CONNELL, M.D., is promoted to be Brigade Surgeon, rear C. WHITE, placed on retired pay. Appointed Assistant Surgeon April 1st, 1901. Surgeon-Major, April 1st, 1902. Surgeon-Lieutenant, April 1st, 1903. Surgeon-Major, April 1st, 1904. Surgeon-Lieutenant-Colonel, April 1st, 1905. He served in the Sudan campaign in 1898, and has the medal with clasp and two Khedive's orders.

Surgeon-Major and Honorary Deputy Inspector-General R. DOMENICETTI, M.D., is appointed Honorary Physician to the General and Honorary General J. IVINA, deceased. Deputy Inspector-General J. DOMENICETTI dates as Assistant Surgeon from April 1902, and as Honorary Deputy Inspector-General from April 1903, when he received the post. He was on the Staff of General Havelock on the first of the latter's campaigns, and was present in the action of Patana on April 18, 1857. He saw Cawnpore, Buseruckrunge, Lucknow, and Agra, and was afterwards at the Alumbagh (shook by the Fall of the latter place). He was also with the 78th Regiment during the latter's capture of General Dutton in two attacks upon his position on the 21st and 22nd.

Surgeon-General J. O'NEAL, C.B., retired pay, and Surgeon-General J. WARREN, have been awarded good service medals. Quartermasters L. GORMAN and E. ENMOUNT, both on retired pay, have received similar rewards.

INDIAN MEDICAL SERVICE

INDIAN MEDICAL SERVICE.
BRIGADE SURGEON-GENERAL COLONEL S. O'R. BAKER, Deputy Com-
missioner, is promoted to be Surgeon-General, August 1, 1904. He was
appointed Assistant Surgeon, March 22, 1878, and became Brigade
Surgeon-Lieutenant-Colonel, February 22, 1890. He was in the
Abyssinian war in 1895-96, and was at the capture of Megeleh, receiving the medal.

Surgeon Lieutenant Colonel E. B. RIVINGTON, Medical Establishment, has retired from the service, which he entered as Assistant Surgeon, October 1st, 1899, becoming Surgeon-Lieutenant Colonel twenty years thereafter.

The retirement is also announced of Surgeon Major A. S. FAULKNER, Bombay Establishment, from January 1st, 1902. He was commissioned as Assistant Surgeon dated 11th September, 1876, and that of Major on Major twelve years later. He was in the Afghan war in 1879 with the Southern Afghanistan Field Force, receiving the D.S.O.

Brigade - Major-General Sir G. H. D. S. O'Connell, Bengal Establishment, is appointed Principal Medical Officer to the Malakand Brigade, which forms part of the force remaining in Central.

SUBJ: HON. COLONEL THOMAS MAUSMILL, the late P. M. C. of Canada, who is at present commanding as brigadier-general of the General Army, has, as is indicated, been seconded for promotion to the rank of Major-General, and will proceed to Malta, where he will relieve Surgeon Major-General Inkson.

THE LESSONS OF THE MADAGASCAR EXPEDITION

[illegible][illegible]

It is the nature of surprise in love, that the troops, utterly worn and on their arrival at the capital, demanded the most abundant supplies and provisions, and that the only accommodation in Paris was in a house

state." It is stated that some of the men for the first few days drew their drinking water from a stagnant pool in Andahalo which is poisoned with sewage, and only used by the poorest inhabitants for washing purposes only. That, when the steamer arrived, a serious epidemic is certainly likely to break out in Antananarivo goes without saying.

Again at Tamatave, as elsewhere in Madagascar, the mortality among the troops—more especially among the levy—is high. The death-rate of the garrison was high, and the military burial parties were "alarmingly frequent" when the strength of the garrison is considered. Emission and retention are marked, for Madagascar fever, the French surgeons noted, induces a fatal cachexia in a far shorter time than any other tropical fever. It is ascertained that this cachexia is reported to be, with great mental depression. It is easily comprehended that "a remarkable number of the sick troops committed suicide."

At Mojanga the hospitals were full of invalided troops sent back from Moatanana and Andriba. These sick and invalided troops were sent home in batches once a month only by Messagerie steamers. Those left behind were disheartened at the prospect of waiting so long as a month before receiving the only chance of recovery, a voyage and change of air, and, losing heart, committed suicide.

The Special Correspondent ends his last letter on the steamer *Yangle*, which called at all the French stations in Madagascar, and pronounces it "a melancholy voyage." He says: "We embarked about 300 invalided officers and soldiers at Tamatave and Mojanga. Most of the men to a great extent recovered their health and spirits at sea, but the death-rate from fever and dysentery was very high; we sometimes lost several men in a day." The worst cases were sent on shore at Zanzibar, where there is an excellent hospital.

The Military Medical Service and the sanitary arrangements on board the steamer were bad. The orlop deck, where most of the sick lay, was offensive in smell, and probably overcrowded. Fortunately, cool weather was experienced in the Red Sea, or the death rate might have been much higher.

No wonder a profound impression was made on the people at Marseilles when they saw successive batches of what the *Times* correspondent terms "human wrecks" landed in their port.

The foregoing is sad reading, and we are irresistibly led to ask, Who should be held responsible? The Commanding-General (Duchesse) has from all accounts creditably conducted a difficult campaign, and the good behaviour of the troops is commendable.

SURGEON-MAJOR-GENERAL HAMILTON.

THE promotion of this distinguished officer, which was announced in the *BRITISH MEDICAL JOURNAL* of November 3rd, appears from the references to it made by the military papers to give general satisfaction in the service; it is equally satisfactory to the medical profession. Surgeon-Major-General J. B. Hamilton has served Her Majesty for some thirty-six years, nearly twenty-seven of which have been spent abroad, mostly in the tropics. He is a graduate both in Arts and in Medicine of the University of Dublin and a Member of the Royal College of Surgeons of England. Entering the army a few weeks after taking his degree, he was sent to the West Indies, and after a tour there to India, where he has served almost continuously since 1825. Throughout his service Surgeon-Major-General Hamilton has done his duty with a singleness of purpose which would have satisfied the Iron Duke himself. In conjunction with Surgeon-Major Evans he worked hard to get the "run rations" abolished, and was instrumental in bringing about the establishment of the canteen system now in force. He has written largely and effectively on subjects connected with the health and well-being of the soldier. He is the author of a monograph on enteric fever, which was very favourably reviewed in these columns, and numerous articles from his pen have been published in the *BRITISH MEDICAL JOURNAL* and the *Indian Medical Gazette*, "Cholera," "The Dark Supply for the Troops," "Nursing in Indian Military Hospitals," "Acute Hepatic Abscess," in which he condemned the use of the aspirator and advocated incision and drainage, being among the subjects dealt with by him.

Surgeon-Major-General Hamilton has always been popular with his own troops, and his real and ability have been greatly appreciated by the general officers under whom he has served.

THE ASHANTI EXPEDITION.

THE medical arrangements for the Ashanti expedition are now almost complete, and, as has been stated, Surgeon-Colonel Taylor will act as the principal officer in this department. In addition to having seen varied service in Canada, India, and Burmah, Surgeon-Colonel Taylor has only recently returned from the seat of war in the East, having been attached to the Japanese army acting against Port Arthur. He will leave Liverpool on Saturday, November 30th, accompanied by five other officers of the Army Medical Staff Corps, for the purpose of settling hospital matters in order. Besides the ordinary field hospitals on shore there will be established a base hospital at Cape Coast Castle, whilst serious cases will eventually be transferred to the hospital ship, which will be some two miles off the coast. This vessel, the *Comandant*, of the Peninsular and Oriental Company's fleet, has just arrived being rapidly equipped under the supervision of the Director of Transport and an officer of the Army Medical Department. She is fitted with the electric light, and will be supplied with refrigerators and double awnings, with the object of minimizing the effects of the tropical sun. Iron beds and bedding will be sent from the War Office Arsenal for the accommodation of 25 officers and 70 men who may be sick and wounded, together with 40 officers and 200 men, convalescent or in hospital.

Special attention is being paid to light, ventilation, and water. The *Comandant* will sail from the Royal Albert Docks on December 6th. The vessel is being fitted up by the War Department, and not by the Admiralty, the stores being those supplied to army hospitals, and differing from those provided for the navy hospitals. She will take out six tons of medical and hospital stores from West India. The ship has been chartered by Government till February 1896. Brigade-Surgeon-Lieutenant-Colonel Townend has been appointed to the medical charge, the other officers detailed being Surgeon-Majors Doid and Porter and Lieutenant and Quartermaster Lines. Three sisters of the Army Nursing Service will also form a

portion of the complement of the hospital establishment—namely, Sisters Gray, McCurdy, and Potts, and a proportionate number of non-commissioned officers and men of the Medical Staff Corps will be embarked as sick attendants. Everything that modern science and experience can contribute towards the efficiency of the hospital in the *Comandant* will be brought into use. In addition to those already named, the following officers of the Army Medical Staff Corps have been detailed for the expedition: Surgeon-Lieutenant Colonel Blennerhassett, Surgeon-Majors Wilson, Wolseley, Wilson, Beatty, Bartlett, and Hillman; Surgeon-Lieutenant Beever (Scots Guards), O'Sullivan, Jossling, Eckerley, Corcoran, Burke, Wilson, and Maher; and Surgeon-Lieutenant Spencer. Several of the foregoing officers have already had considerable experience on the West Coast of Africa.

REGIMENTAL STRETCHER BEARERS AND FIRST AID TO THE WOUNDED.

BRIGADE-SURGEON-LIEUTENANT COLONEL PETER GILES (Welsh Border Brigade Bearer Company) writes: In answer to "Inquirer," the following is the regulation in the German army: There are four classes, equivalent in the English army to: (1) Sanitat = M.O.; (2) Lazareth = M.S.C.; (3) Krankenträger = regimental stretcher bearers; (4) Hulfs-Krankenträger = extra regimental stretcher bearers, embodied only in war.

Nos. 1 and 2 are departmental. No. 3 wear the uniform of their corps, with distinctive collar and facings, and are armed with side arms and revolvers. No. 4 are only for war service; wear their corps uniform, with a red band on their left arm, worn only during an action, and are not protected by the Geneva Convention. Nos. 3 and 4 have fourteen days' instruction each year, and are four per company, raised from men serving with the colours and in the reserve from the infantry, Jäger and Schützen.

Each regiment has 3 M.O.'s, or Sanitat. Each company, troop, and battery has 1 Lazareth or M.S.C. attached to it. In war each division has a Sanitat detachment (M.O., A.M.S.C.) under a commandant and lieutenant consisting of 200 men, 46 horses, 13 wagons. Each army corps has 12 Feld Lazareth, or hospitals, each for 200 sick. There is no brigade medical unit, but in cases where brigades act independently the Divisional Sanitats detachment is split up. In war the Hulfs-Krankenträger, 4 per company, distinguished by a red band on the left arm but not protected by the Geneva convention, succour the wounded, and bring them on stretchers to the Kuppenverbandplatz, where the regimental M.O.'s (Sanitat) are collected, protected by the Geneva Convention; the Krankenträger carry the wounded thence to the Hauptverbandplatz, where the Sanitat (M.S.C.) detachment of the division is; then the wounded are taken in wagons to the Feld Lazareth, or field hospitals, of the army corps.

It will be by this clearly understood that the first line of assistance is not protected by the Geneva Cross, and are said, though double the number of those allowed by English regulations, to be admittedly far too little.

MEDICO-LEGAL AND MEDICO-ETHICAL.

SALE OF PRACTICES.

WE have received a communication from a gentleman in the north of England to the effect that recently, wishing to dispose of a small practice, he communicated with agents, and that as a result a certain doctor visited him, inspected his books, and made inquiries as to the nature of the practice. Our correspondent states that subsequently this same doctor canvassed the village to form a club, took a house, and commenced practice on his own account. Our correspondent adds that this case ought to be a warning to others to make careful inquiries as to the antecedents of persons who may apply to purchase practices. We trust that our correspondent is under some misapprehension, as such a course of conduct in a member of an honourable profession is almost incredible.

In the case of *Fisher v. Foy*, a Dublin surgeon, for *crim. con.* an application was made to the Court of Queen's Bench last week by the defendant to order plaintiff to give particulars of the alleged acts within one week, and the Court made the necessary rule. We are glad to notice that the plaintiff has since written to say that he wholly discontinues the action.

A CARD.

A CORRESPONDENT sends a specimen of a card which, he states, was given recently to one of his patients. The following is the wording of this card:

144, Brecknock Road, N.
With a view of meeting the requirements of a class of persons who are unable to meet the usual charges for Medical Attendance,

DR. MACANN
is prepared to attend Patients either at the above address or at their own homes at the following reduced scale of charges.

CONSULTATION AND MEDICINE, 1s.
Hours—Mornings before 11 o'clock.
Evenings after 7 o'clock (Except Wednesday evenings) at

144, Brecknock Road.
Visits and Medicine at Patients' own homes at any hour, 1s. 6d.

Midwifery, 21 1s. Vaccination, 2s. 6d.

"It must be concluded, from the number of advertisements of this kind which reach us in the course of the year, that this mode of making their existence and their terms known to the public is thought by a certain number of practitioners, not very heedful of the honourable traditions of the profession, to conduce to their advancement in practice. That this is a mistake they will find out sooner or later, but in the mean-

while much injury is being done to the public estimation in which the medical profession has been held. The publicity which we are able to give to such advertisements by reproducing them in these columns has, no doubt, a deterrent effect in the case of those who have not finally determined to sacrifice the good opinion of their fellows, but we look upon it as the duty of all the medical corporations and universities to make and enforce by-laws dealing specifically with the practice of advertisement by members of these bodies. If such advertisers be members of the British Medical Association, which we are glad to think is not often the case, the advertisements should be brought under the notice of the Council of the Branch.

"THE WRONG COMPLAINT."

HENRY WRITES. A. is attending a patient B., who is dissatisfied with A.'s treatment and calls in C., who tells B. that he has been treated for the wrong complaint by A., but does not communicate in any way with the latter. Would it not have been more in accordance with professional ethics and the promotion of neighbourly feeling to do so?

* The alleged conduct of C. in relation to A. is not only the reverse of neighbourly action, but in direct contravention of the following rule: "When a practitioner is called into, or consulted by a patient who has recently been, or still may be, under the care of another for the same illness, he should on no account interfere in the case, except in an emergency; having provided for which he should request a consultation with the gentleman in previous attendance, and decline further direction of the case except in consultation with him. If, however, the latter refuse this, or has relinquished the case, or if the patient insist on dispensing with his services, and a communication to that effect be made to him, the practitioner last consulted will be justified in taking charge of the case; ere assuming which, however, he should satisfy himself that such intimation has been given by the patient or family. Under such circumstances to unjust or illiberal intimations should be thrown out in reference to the conduct or practice previously pursued," etc.—*M. E. Code*, chap. II, sect. 5, rule 9.

UNIVERSITIES AND COLLEGES.

UNIVERSITY OF CAMBRIDGE.

THE VICE-CHANCELLOR.—We are glad to learn that Mr. Charles Smith is recovering from the effects of his bicycle accident; but as he is advised on grounds of health to undertake no business during the remainder of the term, he has nominated the Provost of King's College and the Master of St. John's College as *Interim Vice-Chancellors*.

LECTURES IN MEDICINE.—The *Regius Professor of Physic* (Dr. Allbutt) proposes to lecture on medicine, in reference to cases under the care of the physicians in the hospital, during the ensuing Lent Term. He desires that the names of students or graduates desiring to attend may be sent to him this week.

UNIVERSITY OF EDINBURGH.

At a meeting of the University Court on Monday, November 18th, it was intimated that Dr. Heron Watson had been re-elected and Dr. Joseph Bell elected by the General Council as assessors in the University Court.

Mr. D. A. Welsh, M.B., was appointed one of the clinical medicine tutors in room of Dr. Thillie, resigning.

UNIVERSITY OF DUBLIN ELECTION.

We are informed that Mr. Lecky's London Committee sits daily at Mr. Macorrey's chambers, 7, Fig Tree Court, Temple, and will be glad to give information to medical men in England who have votes for Trinity College, Dublin.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

The following gentlemen having passed the necessary examinations, and having conformed to the by-laws and regulations, have been admitted Members of the college, namely:

Abbott, J. E., L.R.C.P.Lond.
Ash, F. R., L.R.C.P.Lond.
Ashwin, R. H., L.R.C.P.Lond.
Austin, E. D., L.R.C.P.Lond.
Barnes, T. A., L.R.C.P.Lond.
Barnes, A. H., L.R.C.P.Lond.
Barnes, G. C., L.R.C.P.Lond.
Bath, T. D., L.R.C.P.Lond.
Barnes, M. M., L.R.C.P.Lond.
Barnes, J. H., L.R.C.P.Lond.
Barnes, E. R., L.R.C.P.Lond.
Barnes, T. A., L.R.C.P.Lond.
Barnes, A. J. H., L.R.C.P.Lond.
Barnes, L. M., L.R.C.P.Lond.
Barnes, W. I. M., M.D.
Barnes, R. C., L.R.C.P.Lond.
Barnes, H. A., L.R.C.P.Lond.
Barnes, G. E., L.R.C.P.Lond.
Barnes, A. J., L.R.C.P.Lond.
Barnes, A. I., L.R.C.P.Lond.
Barnes, W. A., L.R.C.P.Lond.
Barnes, G. I., L.R.C.P.Lond.
Barnes, G. A., L.R.C.P.Lond.

Clark, R. F., L.R.C.P.Lond.
Cooke, A. M., L.R.C.P.Lond.
Cooke, A., L.R.C.P.Lond.
Cooke, M. A., L.R.C.P.Lond.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

FELLOWSHIP EXAMINATION.—The following gentlemen having passed the necessary examination, have been admitted Fellows of the College: Mr. Thomas Eugene Gordon and Mr. George Arthur Johnston. The following gentlemen passed the primary part of the examination: Mr. Patrick Joseph Fagan and Mr. David Alexander McCurdy.

SOCIETY OF APOTHECARIES OF LONDON.

PASS LIST, November, 1893.—The following candidates passed in:

Surgery.—F. R. Baker, London Hospital; G. F. Y. Hulbert, Birmingham; P. G. Lodge, Leeds and St. Thomas's Hospital; D. Pettigrew, Glasgow and Sheffield; W. O. Piper, Westminster Hospital; E. A. B. Poole, Birmingham; E. H. Tipper, Guy's Hospital; J. N. Wall, St. Mary's Hospital; J. W. Wall, Manchester; H. C. Wainwright, St. Bartholomew's Hospital; J. Wainwright, St. Mary's Hospital.
Medicine, Forensic Medicine, and Midwifery.—W. Beaton, Charing Cross Hospital; E. G. Frederick, King's College; R. B. Jones, Liverpool; J. A. K. Henshaw, Cambridge and Manchester.
Medicine and Forensic Medicine.—F. R. Bradley, London Hospital; C. W. Moorhead, Guy's Hospital; E. H. Tipper, Guy's Hospital.
Medicine and Midwifery.—F. R. Baker, London Hospital.
Midwifery.—R. P. H. Whitmarsh, St. Thomas's Hospital; J. G. Owen, Charing Cross Hospital.
To Messrs. Hulbert, Lodge, Moorhead, Pettigrew, Poole, Reed, Wainwright, Tipper, Wainwright, and Whitmarsh was granted the diploma of the Society.

PUBLIC HEALTH

AND

POOR-LAW MEDICAL SERVICES.

TYPHOID AT PHILLACK.

The action of the Phillack Urban District Council in concerning the owners of a grain store, as having by the storage of decomposing grain caused a prevalence of typhoid fever, would be amusing if it had not its serious aspect. Nuisance, indeed, may have been caused by the decomposing material in question, but there is evidence of a polluted drinking water in the neighbourhood of the fever prevalence, and the fact that analysis had pronounced the water to be unfit for drinking purposes. The report of the local health officer shows that the attention of the Local Government Board has been called to the occurrence, and that they are sending down one of their inspectors to investigate the matter, a step hardly likely to have been resolved upon if the storage of some wheat had been in question. The Council having deemed it unnecessary to have the implicated water analysed, one of their number has had it done privately, both in dry weather and after rain. There is no compulsory notification.

Eight cases have been heard of, with one death; but other cases may be unreported. The health officer speaks of his inspection previous to the advent of the Government Inspector having revealed a state of things that would have surprised his Council had they been with him in his round. The question that occurs to us is whether the Council would not have been nearer the mark if they had censured themselves, and passed a resolution to at once remedy the evils to which their medical adviser so strongly points.

HEALTH OF ENGLISH TOWNS.

In thirty-three of the largest English towns, including London, 4,341 births and 1,362 deaths were registered during the week ending Saturday last, November 23rd. The annual rate of mortality in these towns, which had been 22.1 and 18.1 per 1,000 in the two preceding weeks, further declined to 19.0 last week. The rates in the several towns ranged from 12.6 in Brighton, 13.1 in Norwich, and 13.2 in Croydon to 27.2 in Liverpool, 27.3 in Salford, and 28.3 in Blackburn. In the thirty-two provincial towns the mean death-rate was 20.0 per 1,000, and exceeded by 2.3 the rate recorded in London, which was 17.7 per 1,000. The zymotic death-rate in the thirty-three towns averaged 2.7 per 1,000; in London the rate was equal to 3.6 per 1,000, while it averaged 2.5 in the thirty-two provincial towns, and was highest in Wolverhampton, Burnley, Salford, and Blackburn. Measles caused a death-rate of 2.5 in Salford, 2.6 in Burnley, 2.6 in Wolverhampton and in Oldham, and 2.1 in Blackburn; scarlet fever of 1.0 in Birkenhead; and "fever" of 1.0 in Salford and 1.1 in Sunderland. The 111 deaths from diphtheria in the thirty-three towns included 69 in London, 8 in Birmingham, 6 in West Ham, and 4 in Salford. One fatal case of small-pox was registered in West Ham, but not one in London or in any other of the thirty-three large towns. The number of small-pox patients in the Metropolitan Asylums Hospitals and in the Highgate Small-pox Hospital, which had been 100, 78, and 88 at the end of the three preceding weeks, had further increased to 89 on Saturday last, November 23rd; 30 new cases were admitted during the week, against 20, 14, and 28 in the three preceding weeks. There were 2 scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and in the London Fever Hospital on Saturday last, against 2, 41, 2, 47, and 2, 40 at the end of the three preceding weeks; 26 new cases were admitted during the week, against 25, 30, and 208 in the three preceding weeks.

HEALTH OF SCOTCH TOWNS.

DURING the week ending Saturday last, November 23rd, 812 births and 321 deaths were registered in eight of the principal Scotch towns. The annual rate of mortality in these towns, which had been 21.4 and 18.5 per 1,000 in the two preceding weeks, further declined to 13.1 last week, and was 0.9 per 1,000 below the mean rate during the same period in the thirty-three large English towns. Among these Scotch towns the death-rates ranged from 15.5 in Leith to 23.5 in Aberdeen. The zymotic death-rates in these towns averaged 1.7 per 1,000, the highest rates being recorded in Glasgow and Aberdeen. The 246 deaths registered in Glasgow included 7 from scarlet fever, 6 from whooping-cough, and 5 from "fever." Three fatal cases of scarlet fever were recorded in Aberdeen.

FRACTURES OF CLAVICLE IN POOR-LAW PRACTICE.

INQUIRER writes to ask whether fractures of the clavicle can be regarded as fractures of the arm, and so entitled to be charged for as extras.

"* It has been ruled that a fracture of the clavicle does not come within the regulation which allows fractures of the arm to be charged for as extras.

PUERPERAL FEVER OR SEPTICÆMIA.

DUNRO asks whether he ought to notify as puerperal fever a case of septicæmia supervening on the third day after an abortion at the third month.

"* Without attempting to supply a definition of puerperal fever for the purposes of the Notification Act, we think that it is usual and proper to notify in such a case.

NOTIFICATION QUESTIONS.

MR. WALTER CHAS. ATYWARD (Tunbridge Wells) asks for an opinion on the following case: A patient who lives near the border of two adjoining sanitary districts is attacked by scarlet fever while living in District 1, and the case is duly notified to A, the medical officer of health for that district. For the purpose of isolation the patient is removed to a cottage in District 2. Ought the case to be notified to B, the medical officer of health for District 2?

"* The case ought to be notified to B, unless the circumstances are such that the cottage in District 2 can be regarded as "a hospital in which persons suffering from an infectious disease are received."

MR. A. MAUDE (Wrexham) asks: Is it necessary under the Infectious Diseases Notification Act for a practitioner called in consultation with another to report the case simultaneously with the other practitioner?

"* According to the letter of the Act it is necessary for both to notify.

SCARLET FEVER IN EDINBURGH.

THE number of cases of scarlet fever in Edinburgh is again on the increase, nearly two fresh cases having been reported last week. Unfortunately, too, some cases of a malignant type have appeared. Hitherto the cases have been mostly mild.

MEDICAL NEWS.

THE eighth annual *conversations* of the Royal British Nurses' Association will be held at the Institute of Painters in Oil Colours, Piccadilly, W., on Monday, December 9th, at 8.30 P.M.

Two new convalescent houses, one for males and the other for females, which have been added to the Perth County Lunatic Asylum at Murthly, were formally opened on November 2nd by Lord Balvaird. The new structures will accommodate forty-eight patients and four nurses.

THE Bishop of Stepney will take the chair at a public meeting to be held at Cadogan House, 162, Sloane Street, on December 4th, at 3 P.M., to discuss the means which may be taken to encourage voice training as a branch of national education in accordance with the memorial of the British Medical Association of November, 1893.

PROSECUTION UNDER THE MEDICAL ACT.—The hearing of the case against an alleged unqualified practitioner, to which reference was made by our Bristol correspondent last week (p. 1323), was resumed on November 21st, and, as we learn from the report in the *Western Press*, again adjourned, a warrant for the arrest of the defendant being ordered.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.—On Tuesday, November 19th, the students' annual dinner was held at the Criterion Restaurant, under the presidency of Mr. Spencer, the dean of the school. A large company were present, and, besides past and present students, many of the hospital staff attended, including Dr. de Havilland Hall, Dr. Donkin, and Mr. Bond.

ROYAL BRITISH NURSES' ASSOCIATION.—The first sessional lecture of the season was given on Friday, November 22nd, at 8 P.M., at the offices, 17, Old Cavendish Street, W., by Louis H. Parkes, M.D., D.P.H., on The Importance of Breathing Fresh Air. The Chair was taken by E. A. Fardon, M.R.O.S., Medical Honorary Secretary. The lecture was well attended by members and friends.

A MUNIFICENT GIFT TO THE UNIVERSITY OF CHICAGO.—Mr. John D. Rockefeller has recently given an additional sum of one million dollars and a further contingent contribution of two million dollars to the University of Chicago. These gifts make up the entire amount of the Chicago millionaire's gifts to the University to about 7,600,000 dollars (£1,520,000). This is probably the largest gift ever made by an individual for educational purposes.

SIR CHARLES CAMERON, M.D., was presented at Glasgow on November 26th with his portrait, which bore an inscription indicating that it was given by a large circle of admirers representing all shades of political opinion, in recognition of his services to the public during his twenty-one years in Parliament. The Lord Provost made the presentation. A fountain in honour of Sir Charles Cameron will also be erected at Charing Cross, Glasgow.

THE annual dinner of the past and present students of the National Dental Hospital and College, Great Portland Street, was held at the Holborn Restaurant on November 22nd, under the presidency of Sir Dyce Duckworth. The Chairman in proposing the toast of the evening—"Success to the National Dental Hospital and College"—said that he had within the last few days gone over the hospital, and he confessed that it was a revelation to him. The arrangements were in every way adapted to fulfil the purposes for which they were designed.

MR. GEORGE WIGHT, M.B., C.M. Edin., was at the Central Criminal Court convicted of manslaughter by negligence in the management of a confinement. Mr. Justice Wright, in passing sentence, said that the sentence would have been heavy if the maltreatment had been due to intoxication. He would pass a sentence of three months' imprisonment, but, having regard to the obvious consequences to the prisoner, and the absence of bad intentions, without hard labour. Further, he directed that, until the decision of the Secretary of State was known, the accused should be placed under the care of the medical officer of the prison.

RESTORATION OF THE APPARENTLY DROWNED.—Among the recent recipients of the medals presented by the Royal Humane Society for saving life were the Misses Amelia M. and Alice M. Bigsby, of Clifton House, Deptford, to whose exertions is due the fact that a would-be suicide mother and her child were restored after hope had been abandoned, the mother after three-quarters of an hour's treatment inculcated in instruction by the St. John Ambulance Association and the study of Dr. Sylvester's method of artificial respiration, and the child in one hour and a quarter. The woman had jumped with her child into the Surrey Canal at Deptford, and after some time was brought ashore apparently lifeless. The Misses Bigsby, who had been apprised of the occurrence, hastened at once to the spot and had the bodies brought to their father's house, with the result that their prolonged efforts were crowned with success.

A PAPER on the need for a uniform curriculum for nurses was read at a recent meeting of the Matron's Council by Miss Stewart, Matron of St. Bartholomew's Hospital. Replies, including a very full expression of opinion from Miss Nightingale, received from matrons and others to questions bearing on the subject were considered in detail, and it was urged that registration of certificated nurses by the State was the only means of combating the evils due to the ease with which ignorant and unsuitable women of little or no training obtained employment as fully-trained nurses. A preliminary course of training and a preliminary examination would enable authorities better to discriminate among candidates, and would diminish the number of failures in the first year of training. The mode in which the three years of training should be spent, the establishment of a central board of examiners, the form of certificate to be granted, and the desirability of enforcing payment or an entrance fee, were also reviewed in the paper, and after some general discussion a resolution in favour of a uniform curriculum was adopted unanimously.

ROYAL SOCIETY OF EDINBURGH.—At the statutory annual meeting on November 25th the following members of Council were elected for the ensuing session:—*President*: The Right Hon. Lord Kelvin, F.R.S. *Vice-Presidents*: Professor Copeland, Astronomer Royal for Scotland; Professor James Geikie, LL.D., F.R.S.; the Hon. Lord MacLaren, LL.D.; the Rev. Professor Flint, D.D.; Professor J. G. McKendrick, M.D., LL.D., F.R.S.; and Professor Chrystal, LL.D. *General Secretary*: Professor P. G. Tait. *Secretaries to Ordinary Meetings*: Professor Crum Brown, F.R.S., and Mr. John Murray, LL.D. *Treasurer*: Mr. Philip R. D. MacLagan. *Curator of Library and Museum*: Mr. Alexander Buchan, M.A., LL.D. *Councillors*: Alexander Bruce, M.A., M.D., F.R.C.P.E.; Professor Frederick O. Bower, M.A., F.R.S.; Mr. A. Beaton Bell, advocate; Sir Arthur Mitchell, K.O.B., LL.D.; Professor T. R. Fraser, M.D.; Robert Munro, M.A.; M. D. Noel Paton, B.Sc., F.R.C.P.E.; O. G. Knatt, D.Sc.; Sir W. Turner, M.B., F.R.S.; Sir Stair Agnew, K.C.B.; James Burgess, C.I.E., M.R.A.S.; and John S. Mackay, LL.D.

LONGTON HEARTS OF OAK MEDICAL AGENCY.—The *Newcastle Guardian* gives an account of the annual dinner of this Society, from which it would appear that both the members and their medical officers are contented with the present arrangements. Dr. W. J. Dawes, in replying to the toast of "The Doctors," is reported to have said that, as "he was working in a good cause, the amount of remuneration was secondary to that which he looked on as a great pleasure, namely, doing what he could to assist an agency of this kind, where men combined to assist one another." If the remuneration is a penny a week per member, and there is no wage limit, as we believe is the case in most of the medical agencies in connection with the Hearts of Oak Benefit Society, Dr. Dawes is not to be congratulated on his sentiments, as affecting the interests of his own profession. It may be right enough for working men to combine to assist one another, but it is not quite so easy to see why this should be at the expense of the medical profession. It is equally incumbent on the latter to combine for its own protection, and the common cause is not assisted by utterances such as this of Dr. Dawes, which tend to make the public think the profession are satisfied with the present rate of payment of benefit societies to their medical officers.

THE BELFAST MEDICAL STUDENTS' ASSOCIATION.—The first general meeting of this Association was held on Friday, November 15th, Dr. Donnan, the outgoing President, in the chair. Before proceeding with the business proper of the meeting the chairman alluded to the recent sad death of Dr. Ross, and suggested that the Secretary should be authorised to send, on behalf of the Association, a letter of sympathy to Mrs. Ross in her great misfortune. The suggestion was unanimously adopted. The Secretary's and Treasurer's reports were then read, and showed the Society to be in a satisfactory condition. The office-bearers for the ensuing session were then elected, Dr. Magowan being chosen President, and Dr. Drummond, Dr. Fallerton, Dr. Donnan Vice-Presidents; W. A. Rice, B.A., Hon. Secretary.

MEDICAL VACANCIES.

The following vacancies are announced:

- BROMLEY UNION, Kent.**—Medical Officer for the No. 3 District. Salary, £70 per annum, vaccination fees, and extras about £10. Applications to Robert Gordon Mullen, Clerk to the Guardians, 60, High Street, Bromley, Kent, by December 31st.
- CENTRAL LONDON OPHTHALMIC HOSPITAL, 11, Great St. Andrew's, W.C.**—House Surgeon. Rooms, coats, and light. Applications to the Secretary by December 15th.
- CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.**—House Physician. Appointment for six months. Board and Residence provided and salary at the rate of £200 per annum. Applications to the Secretary by December 15th.
- COUNTY BOROUGH OF BOLTON.**—Medical Officer and Public Analyst, doubly qualified. Salary, £400 per annum. Applications to E. G. Hinnell, Town Clerk, Town Hall, Bolton, by December 31st.
- DENBIGHSHIRE INFIRMARY, Denbigh.**—House Surgeon; must be duly qualified to practise medicine and surgery, and be conversant with the Welsh language. Salary, £200 per annum, with board, residence, and washing. Applications and testimonials to W. Vaughan Jones, Secretary, by December 2nd.
- ENNIS DISTRICT LUNATIC ASYLUM.**—Assistant Medical Officer, doubly qualified, unmarried, and not more than 30 years of age. Salary, £200 per annum, with furnished apartments, ration, washing, fuel, light, and attendance. Applications to Dr. Oulton, Resident Medical Superintendent, by December 15th.
- GLASGOW EYE INFIRMARY.**—Resident Assistant House Surgeon. Salary £50 per annum, with apartments and board. Applications to William George Black, Secretary, 68, West Regent Street, Glasgow, by December 10th.
- HOSPITAL FOR SICK CHILDREN, Great Ormond Street, Bloomsbury.**—House Surgeon to out-patients; non-resident. Appointment for six months but a lifefirst for a second term. Salary, 2 guineas. Applications to the Secretary by December 31st.
- LONDON COUNTY ASYLUM, Claybury, Woodford, Essex.**—Lady Assistant Medical Officer; unmarried; doubly qualified. Salary, £50 per annum, increasing £5 yearly to £75, with board, lodging, and washing. Applications, on forms provided, to E. W. Partridge, Clerk to the Asylums Committee, London Asylums Committee's Office, 21, Whitehall Place, S.W., by December 31st.
- LONDON TEMPERANCE HOSPITAL, Hampstead Road, N.W.**—Assistant Resident Medical Officer, doubly qualified. No salary, but board, washing, and residence provided. Applications to A. W. Hodger, Secretary, by December 6th.
- MONKWEARMOUTH AND SOUTHWICK HOSPITAL, Sunderland.**—House Surgeon; unmarried, doubly qualified. Salary, £50 per annum with board, residence, and washing. Applications to J. G. Jordan, Honorary Secretary, by December 2nd.
- NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney Road, Shoreditch, N.E.**—House Physician; doubly qualified. Appointment for six months; at the expiration of this term he will be required, if eligible, to serve as House Surgeon for a further period of six months. Salary as House-Physician at the rate of £80, and as House-Surgeon at the rate of £50 per annum. Junior House-Physician for six months; doubly qualified. No salary, but board and lodging, including washing, provided. Applications to the Secretary, 25, Clement's Lane, E.C., by December 15th.
- NORTH-EASTERN HOSPITAL FOR CHILDREN, Hackney Road, Shoreditch.**—Ophthalmic Surgeon; must possess special qualifications. Applications to the Secretary, 25, Clement's Lane, E.C., by December 15th.
- NORFOLK AND NORWICH HOSPITAL.**—House Physician and House Surgeon; doubly qualified; unmarried, and under 30 years of age. Salary for each office, £80 per annum, with board, lodging, and washing. Applications to Poole Gabbell, Secretary, by December 15th.
- ROYAL BERR'S HOSPITAL, Reading.**—House Surgeon and House Physician. Salary in each case £50 per annum, with board, lodging, and washing. Also Assistant Medical Officer, with board, lodging, and washing provided, but not salary. Applications for six months. Applications to the Secretary before December 31st.
- ST. GEORGE'S AND ST. JAMES'S INFIRMARY, 60, King Street, Regent Street, W.**—Resident Medical Officer. Salary, £200 per annum with furnished apartments, meals, and lighting; also pension. Applications to the Secretary, 11, Upper Mount, by December 31st.
- ST. MARK'S HOSPITAL, City Road, E.C.**—House Surgeon; must possess a surgical qualification. Salary, £50 per annum, with board and lodging. Applications to the Secretary by December 6th.

SWANSEA GENERAL HOSPITAL.—House-Surgeon. Salary, £80 per annum, with board, residence, washing, and attendance. Applications to Jno. W. Morris, Secretary, 9, Castle Street, Swansea, by December 10th.

TILBURY COLLEGE.—House-Surgeon. Salary, £80 per annum, with board, residence, washing, and attendance. Applications to William McNeil, New Houses, Milne Street, Abertillery, Newport, Mon., by December 6th.

WARRENTHORPE HOSPITAL, Leamington.—House-Surgeon. Salary, £80, with board, lodging, and washing. Appointment for six months subject to re-election. Applications to the Secretary before December 10th.

WEST LONDON HOSPITAL, Hammersmith Road, W.—House-Physician and House-Surgeon. Appointments for six months. Board and lodging provided. Applications to R. J. Gilbert, Secretary-Superintendent, by December 10th.

YORK LUNATIC ASYLUM, Bootham, York.—Assistant Resident Medical Officer. Salary, £500 per annum, with board, washing, and attendance. Applications, addressed to the Committee, to be sent under cover to R. D. Harro, Secretary, by December 10th.

MEDICAL APPOINTMENTS.

AUDEN, Frank T., M.B., C.M. Edin., appointed District Surgeon for the Western District of the South African Republic, *vice* W. H. Haw, M.R.C.S., resigned.

BRACKENRIDGE, F. J., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

CARLYON, F. H., M.B., C.M. Edin., appointed Honorary Surgeon to the Royal Cornwall Infirmary; also appointed Divisional Surgeon to the Cornwall County Constabulary.

CONYFORD, G. J., B.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital (extension).

CORNWALL, J. W., M.A., M.B., B.C. Cantab., appointed Clinical Assistant in the Special Department for Diseases of the Throat at St. Thomas's Hospital (extension).

CRUICK, H. C., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital (extension).

DAVIS, H. J., M.A., M.B., B.C. Cantab., M.R.C.S., L.R.C.P., appointed House-Surgeon to St. Thomas's Hospital (extension).

DAWNAY, A. H. P., L.R.C.P., M.R.C.S., appointed Junior Ophthalmic House-Surgeon to St. Thomas's Hospital.

DIXON, W. E., B.Sc. Lond., L.R.C.P., M.R.C.S., appointed Resident House-Physician to St. Thomas's Hospital.

DYDELL, R., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

EASBY, William, M.D. Brux., L.R.C.P., L.R.C.S. Edin., appointed Medical Officer of Health to the Peterborough Rural District, *vice* W. E. Paley, M.B. Durh.

EWING, Dr., appointed Medical Officer to the East and West Ardley District Council.

FARMER, Gabriel William Stabel, M.A., M.B., M.Ch. Oxon., F.R.C.S., Radcliffe Travelling Fellow, appointed Examiner in Human Anatomy at the University of Oxford, *vice* Professor A. Thomson.

FRASER, W. D., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Electrical Department at St. Thomas's Hospital.

GENOE, G. G., L.R.C.P., M.R.C.S., appointed Junior Obstetric House-Physician to St. Thomas's Hospital.

HALL, Frederick W., M.D. & M.S. Lond., M.R.C.S. Eng., L.R.C.P. Lond., appointed Honorary Assistant Physician to the Sydney Hospital, Sydney, N.S.W.

HARDY, C. M., M.B., B.S. Durh., appointed Medical Officer of Health to the Croft Rural District Council.

HISLUCK, Mr., appointed Deputy Medical Officer of the Kidderminster Union Workhouse.

HOMER, A. L., L.R.C.P., M.R.C.S., appointed House-Surgeon to St. Thomas's Hospital (extension).

KELLYNACK, T. N., M.D., M.R.C.P., reappointed Pathological Registrar to the Manchester Royal Infirmary.

KENT, P. W., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Ear at St. Thomas's Hospital.

KROCKAN, W. D., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Special Department for Diseases of the Skin at St. Thomas's Hospital.

LAYTON, F. G., L.R.C.P., M.R.C.S., appointed Non-Resident House-Physician to St. Thomas's Hospital (extension).

MANNING, Guy E., M.R.C.S. Eng., L.R.C.P. Lond., appointed Resident House-Physician to the Sunderland Infirmary, *vice* Burdon Cox, M.B., resigned.

FRANK, J. L., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital (extension).

RANKIN, W. J., L.R.C.P., L.R.C.S. Edin., appointed Registrar and Assistant House-Surgeon at the County Down Infirmary, *vice* J. Garner, L.R.C.P., L.R.C.S. Edin., resigned.

ROBERTSON, John A., M.D. Glasg., M.B., C.M., appointed Medical Officer of Health to the Stilton Rural District.

SANDERS, E. A., M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., appointed Senior Obstetric House-Physician to St. Thomas's Hospital.

SECCOMB, T. J. A., M.A. Cantab., L.R.C.P., M.R.C.S., appointed Non-Resident House-Physician to St. Thomas's Hospital (extension).

STONE, W. G., M.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., appointed House-Surgeon to St. Thomas's Hospital (extension).

STROVER, H. C., L.S.A., J.A.H. Dub., appointed Medical Officer for the Tempford District of the Biggleswade Union.

THORNTON, W., B.A. Cantab., L.R.C.P., M.R.C.S., appointed Clinical Assistant in the Department for Diseases of the Throat at St. Thomas's Hospital.

THORNTON, F. H., L.R.C.P., M.R.C.S., appointed Resident House-Physician to St. Thomas's Hospital.

THURSTON, E. O., L.R.C.P., M.R.C.S., appointed House-Surgeon to St. Thomas's Hospital (extension).

TOOMBS, H. G., L.R.C.P., M.R.C.S., appointed Senior Ophthalmic Surgeon to St. Thomas's Hospital.

WALLACE, A. R., B.A., M.B., B.Ch. Oxon., L.R.C.P., M.R.C.S., appointed Assistant House-Surgeon to St. Thomas's Hospital (extension).

WILLS, W. Morley, M.R.C.S. Eng., L.R.C.P. Lond., appointed House-Surgeon to the Bristol Hospital for Sick Women and Children, *vice* Dr. W. Ledingham Christie, resigned.

DIARY FOR NEXT WEEK.

TUESDAY.

THE CLINICAL MUSEUM, 211, Great Portland Street.—Open at 3 P.M., Lecture at 4.

PATHOLOGICAL SOCIETY OF LONDON, 20, Hanover Square, W., 8.30 P.M.—Mr. Adams: A New Form of Steriliser and Incubator. Dr. Rolleston: 1. Adenoma of the Sebaceous Glands. 2. Dilatation of the Oesophagus. Mr. Hutchinson, jun.: 1. Gall Stone impacted in Small Intestine. 2. The Formation of Intra-abdominal Bands. 3. Traumatic Separation of the Epiphysis of the Great Trochanter.

WEDNESDAY.

WEST LONDON HOSPITAL, Hammersmith, W., 5 P.M.—Dr. Seymour Taylor: Cardiac Affections in Children (Post-Graduate Course).

OBSTETRICAL SOCIETY OF LONDON, 8 P.M.—Specimens will be shown. Papers: Mr. J. Bland Sutton: On a Case of Tubo-uterine Pregnancy; Primary Intra-peritoneal Rupture; Recovery. Dr. A. E. Giles: A Case of Uterus Bivulvatus, with remarks on the clinical importance of this malformation. Dr. Belfrage: The Effects of Lactation on Menstruation and Impregnation.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen Square, W.C., 3 P.M.—Lecture by Dr. Beevor.

HOSPITAL FOR CONSUMPTION, Brompton, 4 P.M.—Dr. Hector Mackenzie: On Thoracic Aneurysm.

THURSDAY.

ROYAL COLLEGE OF SURGEONS, 5 P.M.—Mr. N. C. Macnamara: The Bradshaw Lecture on Infective and Tuberculous Osteitis as Causes of Arthritis, and the Importance of their Early Treatment.

HARVEIAN SOCIETY OF LONDON, 8.30 P.M.—Dr. M. Handfield-Jones: First Harveian Lecture on the Heart in its Relation to Pregnancy, Parturition, and the Puerperal State.

FRIDAY.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, West London Hospital, W., 8.30 P.M.—Clinical Evening: Dr. Taylor: 1. Malignant Disease. 2. Deformity of Placenta. Mr. Keestley: 1. Radical Cure of Hernia with Undescended Testicle. 2. Loss of Memory associated with Ovarian Tumour. Mr. Paget: 1. Resection of Elbow. 2. Fracture of Sacrum. Dr. Abraham: 1. Primary Chancre in a Child aged 16 Months. 2. Congenital Syphilis. Mr. Bidwell: Sclerositis of Superior Maxilla. Mr. Eccles: Multiple Exostoses.

WEST KENT MEDICO-CHIRURGICAL SOCIETY, Royal Kent Dispensary, Greenwich Road, 8.15 P.M.—Clinical meeting. Cases and Specimens by Drs. Hershbell, E. K. Brown, Morgan Dockrell, Ezard; Messrs. Johnson Smith, Poland, the President, and others.

BIRTHS, MARRIAGES, AND DEATHS.

The charge for inserting announcements of Births, Marriages, and Deaths is 2s. 6d., which sum should be forwarded in post office order or stamps with the notice not later than Wednesday morning, in order to ensure insertion in the current issue.

BIRTH.

EVELYN.—On November 14th, at 24, Micklegate, York, the wife of W. A. Evelyn, M.D., of a daughter.

MARRIAGE.

PATERSON—AITCHISON.—On November 18th, at the British Consulate, Vienna, by the Rev. W. H. Hechler, Embassy Chaplain, James V. Paterson, M.A., M.B., C.M. Edin., to Susie, second daughter of the late John Robert Aitchison, India Office, London.

DEATHS.

BRENNER.—On November 25th, at Strathnam, Canaan Lane, Edinburgh, Bruce Allan Brenner, M.D., L.R.C.S. Edin., late of Bombay, in his 78th year.

DELACHEVOIS.—On November 18th, at West Malvern, Annie Delachevois, M.D., widow of N. Delachevois, Esq., J.P. (7th Dragoon Guards), of Balgilliam, co. Down, and daughter of the late R. J. Tennant, Esq., D.L., Rush Park, Belfast, aged 67. Cremated at Woking, Friday, November 22nd.

HUNT.—On November 22nd, at Tramore, Christchurch, Hants, Godfrey Leicester, only son of H. Rochfort Hunt, M.P., aged 2 years.

LETTERS, NOTES, AND ANSWERS TO CORRESPONDENTS.

COMMUNICATIONS FOR THE CURRENT WEEK'S JOURNAL SHOULD REACH THE OFFICE NOT LATER THAN MIDDAY POST ON WEDNESDAY. TELEGRAMS CAN BE RECEIVED ON THURSDAY MORNING.

COMMUNICATIONS respecting Editorial matters should be addressed to the Editor, 429, Strand, W.C., London; those concerning business matters, non delivery of the JOURNAL, etc., should be addressed to the Manager, at the Office, 429, Strand, W.C., London.

AUTHORS desiring reprints of their articles published in the BRITISH MEDICAL JOURNAL are requested to communicate beforehand with the Manager, 429, Strand, W.C.

CORRESPONDENTS who wish notice to be taken of their communications should authenticate them with their names—of course not necessarily for publication.

CORRESPONDENTS not answered are requested to look to the Notices to Correspondents of the following week.

MANUSCRIPTS FORWARDED TO THE OFFICE OF THIS JOURNAL CANNOT UNDER ANY CIRCUMSTANCES BE RETURNED.

IN order to avoid delay, it is particularly requested that all letters on the editorial business of the JOURNAL be addressed to the Editor at the Office of the JOURNAL, and not to his private house.

PUBLIC HEALTH DEPARTMENT.—We shall be much obliged to Medical Officers of Health if they will, on forwarding their Annual and other Reports, favour us with duplicate copies.

Queries, answers, and communications relating to subjects to which special departments of the BRITISH MEDICAL JOURNAL are devoted will be found under their respective headings.

QUESTIONS.

W. is anxious to know if any cause has been discovered for the rotting of wood in street pavements.

R. M. MEDICAL desires to hear of an institution where an imbecile female, aged 30, otherwise healthy, would be received whose parents can afford about £10 to £12 a year. Near Manchester preferred.

H. M. H. asks: What are the usual terms of contract for attending a large body of men constructing a railway? I am offered £d. a day per man, less one-sixth for collection. I am supposed to supply all medicines and appliances for this.

H. D. asks for information of the value of Haines's golden specific in chronic alcoholism, and whether any analysis of it has ever been made.

* * We know nothing of the composition of this secret alleged remedy, which has been widely advertised for a long time. We have not heard of any analysis having been made.

COMMON SALT FOR RINGWORM.

G. writes: Mr. F. J. Kelly, in his interesting memorandum on the above treatment in the BRITISH MEDICAL JOURNAL of November 23rd, p. 1295, says that he has used it for the past seven years, but makes no mention of more than three cases. He does not state the strength of the solution, nor the mode of application. I presume he only used five applications in each case. Were either of the cases chronic?

ANSWERS.

G. R.—We can only advise our correspondent to consult a surgeon.

W. P., M.B., suggests iodoform internally and as an inhalation.

W. P., M.B., in answer to Dr. J. M. Hermon, BRITISH MEDICAL JOURNAL, p. 1293, begs to refer him to the JOURNAL of 1894, vol. ii, p. 1293.

DR. W. GIFFORD NASH (30, St. Peter's, Bedford) offers to give "F. W. J." information as to Tenorville, where he spent three months this year.

W. P., M.B., writes to draw the attention of "F. W. J." who asked a question in the JOURNAL of November 23rd, p. 1293, to the BRITISH MEDICAL JOURNAL of 1894, vol. ii, p. 1414.

G. G. JAYNE (Edinburgh).—Our correspondent might apply to Mr. Martinale, 18, New Cavendish Street, London, W., or to any leading chemist.

We think that our correspondent "F.R.C.S.Ed." was well advised in desisting to give an anæsthetic to one of his patients who wished to have teeth extracted by an unregistered dental.

W. P., M.B. writes, in reply to M. B. Aberd. in the BRITISH MEDICAL JOURNAL, November 18th, p. 1273, to suggest a thorough physical examination of the lower gut, so as to exclude stricture of the smallest extent. If present, dilatation should be adopted.

ECOMA.—The meetings of the General Medical Council are held as a rule in May and November, and each session lasts from a week to ten days. The Council publishes official minutes, and its proceedings are reported regularly in our columns, as on the present occasion.

D. I.—"Dermographic" is a term applied in connection with factitious urticaria. We have never heard of *Dermographic lupus*, and it is impossible. A case is referred to in *Ames's Medicine*, last edition, in which a medical man, who was the subject of a cancer cut on the head, and was much occupied at the time with tuberculous sputum, developed lupus around the wound in the scalp within a few weeks. An interesting report bearing on the question, by Dr. Alfred Lingard, was published in the *Eighteenth Annual Report of the Local Government Board*

Supplement, containing the Report of the Medical Officer for 1894, p. 462. The report contains numerous references.

MINER.—We cannot prescribe in the BRITISH MEDICAL JOURNAL; nor is anything likely to cure this habit but the resolute and incessant exercise, at all costs, of the patient's own will. He must get good medical advice; probably he must also use means for securing his hands at night. He may find some hope in what Sir James Paget says in his *Clinical Lectures and Essays*: "I believe you may teach positively that masturbation does neither more nor less harm than sexual intercourse practised with the same frequency, in the same conditions of general health, age, and circumstance. . . . I have seen as numerous and as great evils consequent on excessive sexual intercourse as on masturbation. . . . I wish that I could say something worse on so nasty a practice; an uncleanness, a filthiness forbidden by God, an unmanliness despised by men."

REMOTE EFFECTS OF TURBINOTOMY.

MR. CARMALT JONES desires to explain that in his reply on the discussion of his paper at the Section of Otolaryngology reported in the BRITISH MEDICAL JOURNAL of November 23rd, p. 1295, he meant to convey that in some cases of children with ill-developed noses and the passages blocked with hypertrophied turbinates, he had seen the whole nose develop and grow larger after treatment had restored the function of the passages.

INFLUENZA.

DR. GORDON SHARP (Leeds) writes: I would recommend M. L. to try intralaryngeal injections of menthol (10 per cent.) in olive oil for his two influenza patients now suffering from tracheitis and cough and free expectoration. By means of a laryngeal mirror and reflector and a Belling's or Downie's syringe M. L. can, with care, inject a syringeful each night at bedtime, and so secure a night's rest for his patients, and thus do something to putting them on the highway towards recovery. The menthol solution lessens secretion and it has a most soothing effect.

A PARAGRAPH ADVERTISEMENT.

DR. G. D.—The person whose advertisement is referred to is not a registered medical practitioner, his name having been erased from the *Medical Register* some years since for "infamous conduct." His sole qualification, that of M.R.C.S., was also removed by the College authorities. He has been prosecuted for practising and using titles implying that he was registered, and convicted, but, having paid the penalty, continues his practice and assumption of medical titles as before. In any amended Medical Act improvement should be an added penalty in cases where the offence is continued after previous convictions. The paragraph referred to is an advertisement, and paid for, no doubt, handsomely. The newspaper press has a great deal to answer for by the insertion of such, but no amount of moral pressure we can exert, and have exerted, will check the scandal; it is unfortunately a matter of pounds, shillings, and pence.

DENTAL IRREGULARITIES.

A CORRESPONDENT sends us a handbill, or rather a portion of a handbill, issued by a chemist in the South of London. In it the chemist announces that he has made arrangements with "Mr. W. Alfred Allen, D.D.S., Dental Surgeon, to attend daily," and states the "moderate prices" at which artificial teeth are provided, and the charges made for extracting, stopping, and scaling. Such arrangements are to be deprecated, and the circulation of such trade circulars is most derogatory.

ANOTHER CORRESPONDENT inquires whether any means can be adopted to prevent the practice of dentistry for gain by chemists and other unqualified persons, who put "Dental Surgeon" on their plates. To this we may reply that no person can legally call himself "Dentist" or "Dental Surgeon" or by any such title unless he be on the *Dental Register*, published by the General Medical Council. Persons who practised dentistry before the passing of the Act of 1878 were entitled to have their names registered in the *Dental Register*, whether they possessed a dental qualification or not, but the use of the letters D.D.S. (Registered Dental Surgeon) appears to be calculated to mislead the unwary.

We understand that cases in which it is alleged that the provisions of the Dentists Act have been violated will be investigated by the British Dental Association, with a view to action if information is given to the Secretary of that Association, 28, Leicester Square, W.C.

NOTES, LETTERS, Etc.

PRECOCIOUS MATERNITY.

IN the New York *Medical Journal* of November 10th, Dr. C. W. Gleaves, of Wytheville, Virginia, reports the case of a girl born on July 14th, 1894, who on September 10th, 1894, was delivered of a well-formed child, weighing 5 lbs. The ten-year-old mother has menstruated regularly since she was 3 years old, but in development she is still a child. There is no enlargement of the breasts and no secretion of milk. The labour was short and easy, and two hours after delivery the girl wanted to get up and dress. She is now playing about as if nothing unusual had happened. Her baby, which only lived a week, was suckled by its grandmother, who had had a child a few months before.

JUNIOR HOSPITAL ATTACHMENTS AND LOCAL CANDIDATES.

A CORRESPONDENT has sent us an extract from the *Manchester News*, containing a report of the proceedings at a meeting of the governors of the Whitehaven and West Cumberland Infirmary, held for the election of a house-surgeon. The Medical Committee, from thirty-five candidates, sent up six names, arranged in order of merit. The two last names on the list being those of gentlemen whose relatives resided in the district. When the votes were taken the medical was seen to lie between the two local candidates, and one of these was elected. Our correspondent thinks that any but local men might have been spared the trouble

of applying. We gather, however, that the Medical Committee would have preferred that one of the non-resident candidates should have been appointed, on the ground that his qualifications for the post were higher. Under these circumstances we do not see how the applications of non-resident candidates could have been ruled out from the beginning. It is, no doubt, a hardship that young men should be put to the trouble and expense of becoming candidates when the appointment of a local candidate is a foregone conclusion, but this does not seem to have been the case in this instance. The Medical Committee were surely justified in supposing that the governors would take their advice on a point on which the committee were specially competent to form an opinion.

CHURCH CATANTRIL.

REFERRING to a paragraph which recently appeared on this subject in the *BRITISH MEDICAL JOURNAL*, a correspondent in the *Standard* calls attention to the absence of a cloak room as one of the contributory causes of illness in those who attend places of worship. We merely drew attention to one matter pertaining to the church itself, and we by no means suggested that many other conditions might not work in the same direction. There can, we think, be little doubt that there are many evils connected with the too common practice of importing into the sacred edifice wet or snow-laden overcoats, caps, and handkerchiefs, and even umbrellas, to exhale during the service a "pestilential miasma" in immediate proximity to the worshippers, and to render the general atmosphere additionally retentive of the morbid influence of a congress of animals, as described in the *Standard*. The art of making churches comfortable, and providing for their frequenters those luxuries which are taken for granted at all other places of public resort, except perhaps political meetings, is in a somewhat backward state, and in many such matters there is a good opening for reform. We have not yet heard it put forward that church going is regarded by church teachers as a matter of penance, and even if it were, it might be whispered that the artifice attributed to the monks of old of boiling the peas with which on days of pilgrimage their shoes were stuffed, is not unworthy of imitation, and that comfort even in well-doing is not to be despised.

CARBOLIC ACID IN PEMPHIGUS.

DR. T. CHURTON (Leeds) writes: I should be glad to be allowed to correct two slight errors in the report of some remarks of mine at the Leeds and West Riding Medical Society on November 1st. (1) The blood from a patient with typhoid fever showed (not absence of, but) diminution in the number of leucocytes—a condition alleged to distinguish this from the other specific fevers. (2) I have looked in vain for four years—that is, since hearing Dr. Lancaster's paper at the Clinical Society—for any distinctive urticarial rash; and I related a case in which universal pemphigus did not follow but immediately preceded nephritis, the latter disease appearing after recovery from the pemphigus, and being attributed by the patient to chill consequent upon removal of lint, ointment, and bandages from the body generally. With the nephritis she had endocarditis and capillary bronchitis, but recovered in three or four weeks. The cure of the pemphigus after some weeks' duration was very rapid, as often happens; it followed saturation of the blood with carbolic acid applied in a lotion to ulcers on the legs. A recent but earlier and less severe case has also recovered with equal rapidity (two or three days) under the same treatment; but I have seen a sudden recovery when no carbolic acid has been known to be used.

RABIES AND CATS.

AN epidemic in Paris of "enraged cats," as the French call them, says the *Morning*, has called forth some interesting statements from Dr. Chailion, of the antirabic staff at the Pasteur Institute in that city, where from 1,500 to 1,800 persons bitten by mad animals are treated annually. "Contrary to the popular belief," he says, "cats go mad frequently, and about 5 per cent. of the cases we treat are caused by bites inflicted by them. Horses and other domestic cattle are rarely subject to madness. The bites of cats which have gone mad are generally serious and difficult to treat, for two reasons. First, the teeth of the cat are fine and sharp, and the wounds they make are deep, introducing the virus into the system thoroughly. The dog, on the other hand, has larger, blunter teeth, which tear rather than penetrate. Cauterisation is excellent if done immediately in the case of a dog bite, but when the wound is caused by a cat's teeth it is impossible to cauterise more than the edges, while parts below the surface remain impregnated with the virus. In the second place, the dog bites at the hands or legs of the person he attacks, and not often at the face, while the cat almost always attacks the face first, for it can jump more easily and clings with its claws to the clothing. Bites in the face are much more dangerous, because of the proximity of the point of entrance of the virus to the nerve centres, it having a much shorter distance to traverse than if it entered the body through a wound upon the legs or arms. One thing that makes a cat much more dangerous when it goes mad is that it seems to become furious and attacks whatever it sees, while a dog frequently will crouch in a corner and seem to be subject to a sort of partial paralysis."

SCALE OF CHARGES FOR ADVERTISEMENTS IN THE BRITISH MEDICAL JOURNAL.

Eight lines and under	£0 4 0
Each additional line	0 0 6
A whole column	1 17 6
A page	5 5 0

An average line contains six words.

Advertisements should be delivered, addressed to the Manager, at the Office, not later than noon on the Wednesday preceding publication; and if not paid for at the time, should be accompanied by a reference.

Post-Office Orders should be made payable to the British Medical Association at the General Post-Office, London. Small amounts may be paid in postage-stamps.

N.B.—It is against the rules of the Post Office to receive letters at *Postes Restantes* addressed either in initials or numbers.

SOME RECENT OBSERVATIONS [ON INFANT FEEDING.

By Sir WILLIAM O. PRIESTLEY, M.D., LL.D.,

Consulting Physician to King's College Hospital, London.

[The following fragment, read by desire of the East London and South Essex District of the Metropolitan Counties Branch, does not claim any originality. It was intended only to call attention to M. Budin's recent observations, and elicit discussion upon them.]

In the early summer of this year I paid a visit to Paris, mainly for the purpose of seeing my old friend, the celebrated M. Pasteur. He was then so feeble that I feared it was the last time I should see him alive, and he has since gone to his rest amid universal mourning.

While in the French capital I took the opportunity of inquiring what advances were being made in the departments of obstetrics and gynecology, and I was particularly impressed by the admirable and original work respectively of M. Budin and M. Pozzi. I was especially interested in the clinic of M. Budin, where a series of investigations had been undertaken concerning the best way of feeding newborn infants. It is on these investigations I propose to say a few words in the present paper.

A large proportion of medical men in general practice, as well as obstetric physicians, have constantly to consider and give advice on the management of newborn children, and it is a subject which so nearly touches the affections and interests of so many households, that any fresh contribution, placing it on a scientific and successful basis, must necessarily be welcomed by all of us.

In truth, the well-being of infants is so important not only in a domestic sense, but in its relation to the State, that it may well engage the best faculties of the medical man, and not to be left, as it too frequently is, to the bungling mismanagement of ignorant and opiated nurses.

We are all aware that the mortality of children during the first year of life is very large in all countries. In certain portions of France, not more than ten years ago, it amounted to more than 50 per cent.; at Lille in 1850, it actually amounted to 80 per cent. Even in Paris, no longer than ten years ago, it was found by Dr. Lede to be more than 27 per cent. In this country the percentage is apparently not quite so large, but the Registrar-General's reports show a large preventable mortality, and the question for medical men to solve is, how these deaths of young children are to be obviated.

When we look at the domestic surroundings of the poor, the bad sanitary conditions in which we live, and the ignorance from a scientific standpoint they show of the proper methods of feeding and rearing children, we cease to wonder that so many children die in infancy; we rather wonder that so many survive. Unfortunately, of those who live, many, as the result of mismanagement in the early months of life, emerge from infancy enfeebled and stunted in growth; eventually, if they live long enough, they themselves become the parents of a degenerate race. But it is not among the poor only that newborn children are mismanaged; the children of the rich are commonly entrusted to the care of women nurses, imperfectly educated for the important duties they undertake. If they are quick enough, they generally contrive to pick up a little traditional lore from other nurses, whose sources of information are anything but scientific, and who make up for their lack of knowledge by self-assertion and depreciation of the interference of the doctor. The wildest prevailing fallacy among these women is, that infant's food cannot be nutritious unless it is thick, and hence they feed infants soon after birth with various admixtures of farinaceous stuffs which the young stomach cannot assimilate.

All instructed medical men now know that some form of animal milk, without the admixture of any farinaceous material, is the most suitable food for children during the first months of life, but the difficulty hitherto has been to find with exactitude the best substitute for mother's milk, and to prevent misadventures when for any reason the child

cannot be suckled by its own mother. The researches of M. Budin and of his assistant, M. Chavane, have shown conclusively that one of the chief difficulties in the artificial feeding of infants is in keeping the milk of the cow or other animal free from contagion of bacilli which are always floating in the atmosphere, and which, when introduced into the digestive organs, produce green motions and diarrhoea. Milk of every kind is found to be an admirable medium for the cultivation of these microbes, and its exposure to the air for even a short time, more especially with a warm temperature, is sufficient to favour their very rapid development. The result of imbibing these organisms, even in small quantity, is that the child is seized with diarrhoea and vomiting, and these unchecked speedily exhaust vitality and extinguish life.

MM. Budin and Chavane start with the proposition which they cannot too strongly emphasise, that of all ways of feeding a newborn infant, that of suckling by the mother or by a healthy wet nurse is the safest and the best. The substitute of a wet nurse when the mother for any reason is unable to suckle her child is much more prevalent on the Continent than in Great Britain. Even in hospitals, when a woman cannot nurse, the State provides a wet nurse, and there seems to be no difficulty in providing an adequate supply of wet nurses. M. Budin has charge in his maternity hospital of a department in which all the premature babies born in certain parts of Paris are brought together. Here are dozens of small and imperfectly developed infants, some being kept in *cuvettes*, or incubators, to maintain their bodily temperature, and all except those suffering from syphilis or other diseases are nourished from the breast. I saw several of these wet nurses suckling two diminutive babies at the same time, one at each breast. Those whose condition rendered it inexpedient to put them to the breast were fed either with human milk drawn previously from a woman, or on cows' or asses' milk specially prepared for the purpose. In Great Britain there is a certain prejudice, besides the difficulty and expense of providing a wet nurse, and feeding by hand is much more universal.

Most of us know something of the difficulties surrounding hand-feeding, of the small or more serious ailments which spring up in connection with it, and the constant need of prescriptions to combat these inconveniences. But all of us may not have appreciated the true causes of these inconveniences, nor understood that they represent but another link in that chain of microbe pathology which we owe primarily to the researches of the great man who was finally interred, with such well merited honour, at the Pasteur Institute, on November 25th. We have rather been disposed in past times to attribute the derangements of digestion to that indefinite change in the milk which we call "turning sour," or to the casein of cows' milk being too strong for the infantile stomach, and the necessity of further dilution with water. This idea has been strengthened by observing the masses of undigested curd passed in the evacuations. When some other food has been added to the milk, this perchance has been blamed for the derangement.

M. Budin's researches clearly indicate that next to mother's milk, the milk of some other animal, like that of the ass, the goat, or the cow, and thus undiluted with water but properly sterilised, is absolutely the best. As the milk of the cow is the most readily available, this is used by M. Budin, and his experiments were made chiefly with cows' milk.

Since it was discovered that various zymotic diseases have been produced by drinking infected milk, various sanitary authorities have impressed upon us as a measure of precaution the necessity of always boiling milk for household purposes, and there can be no doubt that boiling is a very effective method of sterilising milk. But boiling milk has unfortunately the effect of giving it a disagreeable taste, and it seems besides to have the effect of so firmly coagulating the casein as to render it less easily digestible for the infantile stomach. The method of sterilising milk recommended by M. Budin is to allow it to remain in a bath of boiling water, a *bain marie*, as he calls it, for forty minutes. The apparatus he advises consists of a series of bottles, each capable of holding a child's meal, and furnished with india-

rubber stoppers. These bottles are placed in a pan of water or water bath, which is kept boiling for the prescribed time. The covers or stoppers are so adapted that they allow vapour to escape during the heating process, but as the bottles cool they are drawn down into the opening by atmospheric pressure, and fit like suckers into the orifice, thus showing that they are airtight. It is a notable fact, not generally known, that it requires a higher temperature to boil milk than water, and consequently milk can be immersed in boiling water for forty or more minutes, without being itself boiled. The temperature is, however, raised high enough to disinfect it of all the commoner germs of disease, while the flavour of boiled milk is not imparted to it; indeed, the taste is little altered from that of new milk. But the additional advantage gained is that the curd of the milk is separated into minute particles or flocculi and so softened that it does not form hard concretions in the digestive tube of the infant. It is much better adapted, therefore, for infant feeding, and is likely also to be of great use in the case of adults who have feeble digestion, or for other reasons find ordinary milk objectionable. M. Budin deprecates very much diluting milk with water or even barley water for infant feeding. He holds that it is much wiser, and more in the interests of the child, to give a smaller quantity of pure milk properly sterilised than a larger quantity diluted with water. In all the observations made in reference to this point he found that the greater quantity of fluid, necessitated by dilution, tended to derange digestion, while the normal and progressive increase of weight was not maintained. Always supposing that too large a quantity of sterilised milk was not given, and it was regulated in accordance with the age or needs of the child, there was no difficulty in the assimilation of the pure milk.

M. Budin insists that both in hospital and private practice the progressive wellbeing in the infant is best ascertained by weighing it. In his hospital the children are weighed every day, and their weight is registered, so that an increase or diminution is readily observed. He has constructed an ingenious table which serves as a register. In the first column are figures in grammes, the lowest ones at the bottom, with an ascending scale. The days and weeks are indicated along the top, and thus a curve may be traced with pen or pencil, as in temperature charts. Even under normal circumstances the weight of the child drops a little during the first week after birth, but after that time it ought steadily to advance. In the charts alluded to, whenever water was added to the milk there was always a little drop in the curve, showing that less nourishment had been absorbed, and a like drop was noticed if, perchance, the child had diarrhoea, or catarrh, or other infantile ailment, showing that nutrition was impaired. To make the sterilisation of milk effective, great care must be taken to exclude every source of infection from germs which may get access to the milk after the process is completed, either in the vessels themselves or in the apparatus used for feeding. Many of the misadventures were found to arise from lack of precaution in this respect. Sometimes the milk, after being duly sterilised, was again exposed for some time to the air before being used, and thus became again the medium for development of bacteria, more especially in a warm atmosphere. The Académie de Médecine in Paris does not think it beneath its dignity to express an opinion on babies' feeding-bottles, because it concerns a matter of vast importance to the community, and it has emphatically condemned all feeding-bottles with long and complicated tubes, because it is impossible to keep them clean and sterilised. Consequently they become the nidus for bacterial development, particularly at the joints. The simplest bottle, which can be sealed throughout is the best, but there may be great difficulty in persuading poor women to adopt them, because although a siphon bottle may be the means of poisoning her baby, yet she can put it beside the child in its cot and go about her other occupations, leaving it to absorb its nourishment automatically.

If pathogenic organisms can be prevented getting access to the digestive organs of young children, one of the most fertile sources of infantile diarrhoea would be removed and the mortality from this cause greatly lessened.

Sterilised milk seems in certain cases actually to be a remedy for infantile diarrhoea, for always supposing that a

fresh supply of irritating organisms is not poured continuously into the digestive canal, Nature will eliminate the poison up to a certain amount, and then untainted milk is retained and becomes nutritious.

If M. Budin's deductions turn out to be correct—and he is a careful and earnest observer—the use of condensed milks may to a large extent be discarded; these have crept largely into use, and no doubt are very convenient in emergencies. They may seem to answer for a time, but in my experience they are very defective sources of nourishment, and should never be employed when fresh milk can be procured. Dr. Barlow, who has written so ably on infantile scurvy, believes that by the condensing process milk loses its antiscorbutic property, and so favours scurvy in children. This may possibly occur when milk is boiled, but the risk is minimised when it is simply sterilised and not boiled.

To sum up M. Budin's conclusions, therefore, one may say:

1. That he regards breast milk as absolutely the best and safest nourishment for an infant, and that when a mother cannot nurse her own child the best substitute is a good wet nurse.

2. When artificial feeding must be had recourse to, cows' or another animal's milk sterilised by the method alluded to is by far the best substitute, but even when milk has been sterilised it must be guarded by certain precautions, and the simplest feeding bottle is the best.

3. Sterilised milk is best given undiluted with water, the quantity given to vary with the age of the child and other circumstances.

This, I presume, implies that the child is in normal health. If any derangement of the digestive organs or other abnormal condition is present, dilution with barley water or other modification of food, may be required as well as medicines.

He objects to all farinaceous forms of food during the first year of life.

The method of sterilisation of milk as recommended by M. Budin is not new, and he does not claim any originality in this respect. Inexpensive apparatus for this purpose is to be found with many instrument makers. I learned quite lately that the calves used for vaccination at the National Vaccine Institution are now fed on sterilised milk to keep them healthy. It would certainly be a satire if we were not to adopt the same measures of safety for human beings which we provide for the lower animals. Sir Dyce Duckworth, who has just returned from America, tells me that a system is gradually making way there in which medical men habitually write prescriptions, expressing the exact amount of casein of cream and of sugar which milk is to contain in accordance with the age and condition of the infant. The milk is at the same time carefully sterilised. In Boston and New York especially laboratories have been established to make up these prescriptions. Sir Dyce has furnished me with a pamphlet by Professor Rotch of the Harvard University, in which all the details are set forth with great ingenuity and clearness.

This is bringing the science of feeding children to very exact proportions, but entails great trouble and possibly expense. Budin's and Ohavane's method, if generally successful, can be more readily adopted for domestic use, as it is very simple and entails little expense. The more elaborate one may be reserved for special cases or until it is more generally available.

INTERNATIONAL PRIZES IN BACTERIOLOGY.—The Argentine Medical Club of Buenos Ayres has decided to honour the memory of Pasteur by offering prizes for bacteriological research. Competitors must submit original unpublished researches relative to some point of bacteriological technique, or to the bacteriology (etiology, diagnosis, prophylaxis, and treatment) of the infectious diseases of man or animals, or to the industrial applications of microbiology. Papers, specimens, preparations, cultures, and photographs must be sent before May 31st, 1897, to the President of the Argentine Medical Club, Calle Corrientes, 2038, Buenos Ayres. Papers, which must be authenticated by a motto in the usual manner, may be written in Spanish or in French. The first prize will be a sum of £80, the second £40, the third a diploma of honour.

ON THE MANAGEMENT OF CASES DURING THE PERIOD IMMEDIATELY FOLLOWING OPERATION.¹

By SIR THORNLEY STOKER, Hon. M.C.H.R.U.I.,

President, Royal College of Surgeons, Ireland; Surgeon to the Richmond Hospital and to Swift's Hospital; Fellow of the Royal University.

WHEN I last had the honour of addressing you from this chair, I took occasion to apologise for speaking on a vulgar instead of an obscure or novel subject, and I am again disposed to use my opportunity to a like effect. I do not presume to address myself particularly to the more senior portion of my audience; but there are a large number of the younger members of the Academy present, and to them I venture to say something about a subject which exercised me much in my younger days, which does so still, and which is important because of its very commonness, and worthy of attention because it is sometimes overlooked.

I refer to the management of patients during that oftentimes critical period between the performance of a surgical operation and the moment at which, the risks consequent on it having passed, the patient becomes free from immediate and non-particular danger. This is the period occupied by two conditions of depression common to any or all operations, and therefore to be considered by themselves, apart from special dangers proper to individual surgical procedures. They are (a) shock and (b) exhaustion consequent on vomiting.

They may not be present, or being present, may vary in duration from a few minutes to several days. Their intensity cannot be foretold; it may be but slight or may be grave even unto death, and nothing in the condition of the patient, the nature of disease, or the character of operation can afford any reliable evidence as to their possible severity. They may be serious in those who are vigorous, and unimportant in those who are weak; the very young and the aged may suffer from them but slightly and persons of middle life may be in peril; they may follow the most trivial operation and be absent from the most severe.

Those who have had experience in surgery know how often they meet surprises in the immediate consequences of operation. Sometimes the experience is the pleasant one of finding the treatment borne better than was expected; sometimes it is the sad one of danger following an operation when it was not looked for. The lesson we learn is never to neglect during and after operations every detail which can lessen danger by diminishing the chances of shock or exhaustion, and which can assist subsequent reaction.

The causes which tend to produce shock are numerous, and for the most part obscure. There are many states of enfeebled health, of particular debility, and of other recognised conditions which predispose to it. But there are unseen and often unexpected circumstances which may lend themselves to its production. Operative measures should, therefore, never be approached without the most careful general examination of the patient and the most thoughtful consideration of his physical position. It is impossible to formulate exact laws in this direction: these perceptions are largely matters of experience, and only time and clinical study can develop them. But from long observation we know that such considerations of the general state of a patient about to be submitted to operation are often overlooked or disregarded, and I suppose most of us have had bitter regret of our want of perception.

In addition to general matters concerning the patient there is one particular which is proper to the surgeon, and in which great error is common—I refer to the undue prolongation of operations. Two circumstances have, in our generation, lent themselves to this: one is the facility afforded by the use of anesthetics; the other the extreme care, conservatism, and attention to detail, begotten by the in-

roduction of antiseptic methods. There is no one circumstance which so tends to the production of shock and to the exhaustion produced by subsequent vomiting as prolonged anesthesia. I have had this impressed on me by severe lessons, and I am satisfied that we should watch ourselves very closely in this direction, and sacrifice detail and conservative measures in instances where they demand the unsafe prolongation of anesthesia. I can look back on cases where I regret the time spent on an operation; for instance, the only example of elected operation for the radical cure of hernia which has ever proved fatal in my practice was one in which, in my anxiety to conserve the testis in an extremely complicated rupture, I prolonged the dissection to such an extent as to produce shock from which the boy never rallied. I know now that had I removed the organ I could rapidly have concluded the treatment and saved the patient.

What I have said of the production of dangerous shock is largely true of exhaustion immediately following operation. Given the conditions, known and unknown, which predispose some patients to it more than others, prolonged anesthesia, with its often attendant vomiting, is its most usual provocative. We will generally see post-operation vomiting proportionate in severity and persistence to the duration of anesthesia.

So much for causes of shock and vomiting: what of the means of avoiding them, and of relieving them if they occur? It is a truism to say that prevention is better than cure, and it will be seen from what I have said that a due despatch in the performance of operations, and a consequent shortening of the period of anesthesia is the most important direct measure to attend to. To an audience like this I need not elaborate this part of my subject; indeed, I could not if I would, for there are a hundred various conditions and circumstances which must guide us, and their knowledge and application are among the matters which make the difference between one surgeon and another, and which lend themselves to our successes or contribute to our failures. Shock and vomiting are so much due to the same causes, and so subject to the same remedial measures, that it is difficult to consider them apart. I have learned to rely on three agents only for the relief of shock: (1) Heat; (2) alcohol; and (3) morphine or opium. Concerning the first of these, we generally find that if the surface of the body can, by the use of hot applications, be brought to a wholesome warmth, the danger has been overcome. If to the use of hot water, contained in bottles, or, better still, in small india-rubber bags, we add rubefacient applications of mustard to the extremities, about the region of the solar plexus, or over the heart, we have a valuable armament for the inducement, not only of heat, but also for the production of a physiological stimulation.

If these measures fail, or response to them is too slow, alcohol must be resorted to. It should be given by the rectum, not only because vomiting may exist, or may be induced by the introduction of stimulants into the stomach, but also because when shock is present the stomach has little or no power of assimilation. The possible necessity for rectal stimulation and alimentation after operation is one of the reasons why the bowel should always be thoroughly cleared before any procedure, however slight, in which anesthesia is to be employed.

Failing by these measures to induce reaction, opium or morphine has to be resorted to. If rapid effect is sought morphine is the most useful agent, and it is also that which best controls vomiting. But where there is no vomiting, and where the stimulating effect of the drug is our chief aim, opium itself is to be preferred; it must be given by the rectum. No rule can be laid down for the dosage in these cases, beyond the two points that are to be borne in mind: first, that opium is tolerated in large quantities by persons suffering from shock, very much as those bear it who have lost much blood; and, secondly, that it must be given intelligently, that is to say, given watchfully, dose following dose, until the due effect is produced. The value of morphine given hypodermically, or of opium administered by enema in all cases of depression due to shock, cannot be overestimated. I can look back on lives lost after operation from shock and exhaustion, which greater clinical experience and more courageous use of morphine

Address delivered at the opening of the Surgical Section of the Royal Academy of Medicine in Ireland for the session 1895-96.

or opium would now enable me to save. If it be sought to study the effect of opium as a stimulant, it cannot be better seen than by watching its effects in the shock and collapse following extensive burns. I have to thank the help afforded by modern nursing developments for much wholesome change of opinion in these matters. It has only been since the introduction of trained women to the bedside, with their watchful intelligence and careful skill, that I have learned properly to deal with cases after operation. That intuitive faculty, amounting to what used to be miscalled an "instinct," and which is the special property of women, finds its best expression in the study and management of difficulties like those I speak of.

Of the treatment of the usually more persistent condition of vomiting, with its attendant exhaustion, much need not be added to the limited list of measures employed in the treatment of shock. Warmth, rectal stimulation, and the hypodermic syringe again find their use. If to these I add rubefaction, or occasionally limited blistering over the stomach, I have enumerated all the means I find most excellent. The host of drugs recommended to check vomiting are, in my experience, worse than useless; they are not only ineffectual, but they add seriously to the gastric disturbance. One measure, introduced of late, we are trying in the Richmond Hospital. I mean the use, for some hours after operation, of a mask charged with vinegar. We are not yet in a position to speak definitely about this treatment, but it seems to give promise of success in cases where chloroform has been the anæsthetic. The rationale of its action is simple; the chloroform which is exhaled by the lungs is decomposed during expiration into chlorine and formic acid. The chlorine, by its irritation of the tracheæ and larynx, is probably the cause of vomiting, and being taken up by the acetic acid, is rendered harmless. But so far as present experience carries us, the hypodermic use of morphine is the cardinal remedy for the species of vomiting of which I speak. It must be used intelligently, fully, and fearlessly, and will exercise its effects both as a stimulant and as a gastric sedative far beyond those of any other remedy.

If it be conceded that it is useless to introduce stimulant or aliment into the stomach of a patient suffering from shock, it will be granted that it is not only useless but improper when vomiting is present; and here a previously cleaned rectum serves its owner well. Stimulants associated with such nutriment as can be readily absorbed should be periodically introduced. It is generally found that vomiting any more than shock does not persist with a warm surface, and therefore the three remedies I have indicated should be employed in the same sequence as in shock; first, heat; second, rectal stimulation and nourishment; and third, morphine.

The distressing symptom of thirst is one which gives great trouble. There is nothing I have learned to discredit more thoroughly for the relief of thirst than ice. It increases thirst both directly and by the induction of vomiting. The emesis it produces is due to the quantity of water the sucking of ice insidiously introduces into the stomach. Nothing should be put into the stomach in these cases, so that ice is not only useless, but hurtful. Thirst is best relieved by frequent rinsing of the mouth with hot water, and by the occasional introduction of two or three ounces of warm water into the rectum.

In what I have said I have avoided speaking of details and methods; I have remembered that, although some of us are younger and less experienced than others, all of us in this room are educated in the factors of surgical science, and I have therefore tried to be suggestive rather than didactic, and to avoid details except in so far as they were necessary to the elucidation of principles.

If I may reduce to formulae the matters I have referred to, I would put them thus:

1. That the tendency to prolong operations must be carefully guarded against, as it is a grave cause of danger.
2. That in the treatment of shock and vomiting following operation we get no help from the stomach, and must rely on the rectum as its substitute.
3. That heat, alcohol, and opiates are our best remedies; and that the latter are well borne, and must be intelligently used to their full effect.

4. That drugs of the class ordinarily used to check vomiting are of little or no use in the cases under consideration.

5. That ice does not relieve thirst, and does harm by introducing water into the stomach and so provoking vomiting.

THE BRADSHAW LECTURE ON INFECTIVE AND TUBERCULOUS OSTEITIS AS CAUSES OF ARTHRITIS IN CHILDHOOD, AND THE IMPORTANCE OF EARLY TREATMENT.

Delivered before the Royal College of Surgeons of England.

By N. C. MACNAMARA, F.R.C.S.,
Surgeon Westminster Hospital.

I PROPOSE in this lecture to consider how it is that the extremities of the long bones entering into the formation of various joints are peculiarly liable during childhood to become the breeding ground of certain forms of micro-organisms, and so to be affected with osteitis, and then to inquire by what means we can best dislodge such parasites before they have destroyed the tissues among which they may have taken root. It will be necessary to confine my remarks to a typical example of acute and of chronic inflammation of bone produced by two well-defined microbes, and to illustrate the subject by reference to disease of the knee; this joint, being one of the largest and most superficial articulations of the body, affords us a favourable opportunity for determining the nature of any morbid action taking place in the bones entering into its formation.

The condyles of the femur at each step we take have to bear the weight of the body, which in like manner is supported on the upper surface of the head of the tibia, so that these opposing portions of bone are constantly subjected to considerable pressure and to concussion. This pressure, in consequence of the comparatively soft condition of the osseous tissue in childhood, is largely distributed throughout the trabecular tissue contained within the extremities of the bones which enter into the formation of the joint. The trabecular network within the extremities of the long bones is also subjected to traction, especially at the point of union between ligaments and tendons with the bones. So intimate is this union that in cases of violence tendons not infrequently tear away portions of the cancellous tissue as well as the compact outer layers of the bone into which they are inserted. It follows, therefore, that the trabeculae contained in the extremities of these bones have to bear their share in the frequent wrenches and strains to which the joints of children are subjected; and it is within the meshes formed by the interlacing of these trabeculae that the red marrow of the bone is contained; red, because it is full of blood, and among the other functions which it has to perform is that of manufacturing the red blood corpuscles. Beyond this the trabeculae are lined with cells from which in childhood the growth of the epiphysis, and at the juxta-epiphysal line the increase in length of the shaft of the bone takes place, necessitating active and extremely complicated physiological changes in the organic matter through means of which growth is effected.

We may form some idea of the activity of the work going on within the bones entering into the formation of the knee-joint from its abundant supply of blood vessels; the four articular arteries, the azygos, and branches of the tibial and femoral vessels all send numerous offsets into the bones; in fact the condyles of the femur and head of the tibia are riddled with openings through which vessels pass into and leave the cancellous tissue. Within the bone the arteries break up into narrow vessels which open into a plexus of peculiarly wide venous capillaries, and these into veins which have to pass out of the bone through unyielding channels which perforate the dense external layers of the bone. The circulation of blood, therefore, through the thin-walled venous capillaries in the marrow of bone is much delayed, and it is in this sluggish stream of blood that the nucleated cells are converted into red blood corpuscles.

Within the cancellous tissue of the long bones we have therefore highly vascular delicate soft structures through which the circulation of blood is much impeded, and these tissues during childhood, as already explained, are peculiarly liable to contusion by external force. Beyond this the marrow contains numerous cells through means of which the growth and repair of the bone is effected. We are apt to overlook the important and extremely complex nature of the process of growth; it means a vast expenditure of physiological action, and an almost inconceivably complicated arrangement of the constituent elements of the organic matter engaged in the process. But the more complicated the machine, the less its stability, and consequently the greater the danger of its component parts being disarranged. And it is in organic matter which has been contused, or in which the constituent parts have otherwise been much disturbed, and its vitality thus lowered, that micro-organisms take root, and so we can comprehend why it is that the marrow of the cancellous tissue in the ends of the long bones during childhood are not infrequently the breeding ground of various forms of microbes.

The vulnerability of the tissues of young persons to the action of microbes is exemplified by the eruptive fevers from which they suffer; also by the susceptibility of European recruits to tropical influences on their arrival in India. As we advance in life the ends of the long bones become surrounded by layers of dense unyielding osseous tissue, which to a large extent preserves the soft structures contained within the cancellous tissue from injury; the process of growth has also been completed, and the tissues have become more stable; it follows therefore that acute infective or tuberculous osteitis seldom commences in the joints of persons who have passed the age of childhood.

It is hardly necessary to observe that the bones increase in length by the growth of osseous tissue at the juxta-epiphyseal line, and that at this line in the growing bone the trabecular network is composed of temporary, that is of brittle, bone in which the venous radicles pass up to the epiphyseal cartilage, and there form loops more like sinuses than ordinary veins. One or two arteries from the diaphysis pass through the cartilage into the epiphysis, but by far the greater part of the blood supply of the epiphysis is independent of that of the diaphysis; in fact, the shaft of one of the long bones may become necrosed and be removed, and yet the epiphysis may continue to live and grow. Muscular force is capable of causing the complete detachment of an epiphysis, and fractures not infrequently occur through this line. Short of such extensive injuries, ecchymosis and laceration of the fragile and rapidly growing structures at the juxta-epiphyseal line must be of common occurrence in childhood.

The circumference of the epiphyseal cartilage is prolonged into the deep layer of the periosteum of the diaphysis, and its cells produce the osteoblasts of that layer; the extremities, therefore, of the diaphysis in the growing bones of children are enclosed in a cup-like cavity of cartilage, and if acute inflammation should occur in the brittle tissues at the juxta-epiphyseal line, the products of the inflammatory action must find an exit either through the trabecular network of the extremity of the diaphysis into the medullary canal, or between the deep layer of the periosteum and the outer surface of the bone. In either case the blood supply of the diaphysis is cut off, the periosteum being stripped from the bone, and the pressure of the inflammatory products against the unyielding trabeculae and Haversian system prevents the circulation of blood through the shaft of the bone, and it consequently becomes necrosed; but the deep layer of the periosteum having been forced outwards with the surrounding vascular structures may continue to live and form a case of new bone around the necrosed diaphysis.

Professor Ollier, in the year 1881, published the results of some experiments he had made on the dead bodies of children which illustrate the point above referred to. He found that only slight force applied in certain directions was sufficient to injure, and often to lacerate the soft tissues at the juxta-epiphyseal line. If the force was increased the injured structures could without difficulty be squeezed outwards beneath the deep layer of the periosteum, but not into the external soft tissues or round the epiphysis. Ollier also

states that in the case of children who had died from tuberculous or from septic poisoning the structures at the juxta-epiphyseal line were peculiarly friable. Without doubt a young and healthy bone, like that of a branch of a living tree, is a very different thing from the same part after death; but among our poor, neglected, anemic, London-bred children the tissues are often, as regards their vitality, not far removed from dead structures. We can readily conceive that the organic matter which forms the bodies of these children is less capable of resisting the attacks of micro-organisms than those of more robust and well-cared-for beings. One seems to realise this difference when before the days of Listerian surgery one saw the swarms of ants and flies which attacked in a climate like that of Calcutta the wounds of persons whose vital powers were at a low ebb. And so with micro-organisms; their opportunity is in structures which have been contused or their vitality depressed by some other cause; it is in organic matter of this kind that microbes take root.

Bacteriologists teach us that micro-organisms of a dangerous character may remain quiescent in our bodies; at any rate they can live there without exciting any active disturbance, for they seem to be under the control of constituted authorities which they evidently respect; but if these salutary forces are incapable of performing their functions, or if the microbes alight on a soil composed of weak or injured tissues, they fix themselves on such matter and grow with amazing rapidity, and by means of the irritating chemical compounds they cause inflammation in the neighbouring tissues.

To illustrate this point we may again refer to the East: there at the end of the hot season we pass over a large expanse of land with no vestige of animal or vegetable life on its surface, the earth is bare, scorched and fissured in all directions, having for weeks been exposed to the uninterrupted heat of a tropical sun. Suddenly a storm bursts over the country and a deluge of rain falls; with its first drops the whole plain is alive with a multitude of insects and frogs, whose loud croaking fills the air; a mere shower of rain has been sufficient to bring a vast amount of dormant life, including the cholera and other bacilli, into active being. And so with the human body. I must have swallowed large quantities of water infected with the cholera bacillus during my service in Lower Bengal, but on one occasion only, and that from my own fault, they found my intestinal canal unprepared to resist their attack, and then they nearly killed me; the shower of rain had come for them and they took advantage of it. In like manner we can account for the action of unripe fruit or unwholesome food, saline purgatives, and so on, as predisposing causes of cholera; they prepare the surface of the intestines as a fit breeding ground for the cholera bacillus.

Clinical experience had convinced me some twenty years ago that cases of acute inflammation at the juxta-epiphyseal line depended on causes such as those described, that is, on injured tissues which had fallen a prey to a specific microbe. These ideas have since been confirmed by experimental research, for Mr. A. H. Tabby has shown that among animals acute inflammation of the structures forming the juxta-epiphyseal line may with certainty be produced if this part be mechanically injured, and then the staphylococcus pyogenes aureus is introduced into the circulation of the animal. The result of this treatment is an intense inflammation of the injured osseous tissues, which rapidly swarms with this microbe, leading to dangerous septic poisoning. In animals where similar injuries had been inflicted at the juxta-epiphyseal line, but in which the staphylococcus had not been introduced into the blood, no acute inflammation occurred in the damaged tissues or in any other part of the body.

And so if one of our weak city-bred children—especially those who have lately passed through one of the eruptive fevers—happens to suffer from traumatism at the juxta-epiphyseal line, say of the upper extremity of one of his limbs, and if at the same time the part becomes infected by the staphylococcus pyogenes aureus—probably introduced into the circulation through some open sore—acute inflammation is excited in the injured bone, so acute and so dangerous that more than half these patients die within the course of a few days. Should the child outlive the onset of the disease, pus forms in the inflamed bone, and for reasons already given it burrows into the diaphysis and between the

deep layers of the periosteum and the bone, leading to necrosis of the shaft of the tibia. In the less severe cases the inflammatory action may be limited and produce a circumscribed and chronic abscess in the extremities of the bone, such as those first described by Sir B. Brodie. It is quite possible, when the juxta-epiphyseal line of the upper end of the tibia is involved, that pus may pass into the knee joint—a condition described and figured by Mr. Thomas Smith in his paper on this subject published in the *Bartholomew's Hospital Reports* for 1877; in these cases it is probable that the infective micro-organism from the juxta-epiphyseal line finds its way along the walls of one of the vessels which pass from the diaphysis through the epiphyseal cartilage, and so reach the joint. However this may be, the knee may become acutely inflamed, but is by no means necessarily involved in cases of acute infective osteitis.

If, therefore, we rightly comprehend the nature of this form of disease, its treatment would seem to be clearly indicated, for it is evident that we must endeavour to destroy the living organism which is at the root of the mischief. Incisions into the periosteum, however important they may be, do not reach the source of the disease; to do this we must open the bone at the juxta-epiphyseal line and wash out the infected tissues with a germicide, subsequently maintaining free drainage from the interior of the inflamed bone outwards into antiseptic dressings. We do wrong to wait for pus to form in cases of this description, or in delaying opening the bone for an hour after we have diagnosed the nature of the disease; for the micro-organisms which are at the root of the mischief, as a rule, live and multiply with great rapidity in the part until within a short period they destroy the life of the individual they inhabit, or cause their own death in the suppuration they give rise to in the tissues. The question, therefore, as to when we should operate in cases of this description is answered by directing the bone to be opened immediately we have determined the nature of the disease; remembering that the operation is attended with no danger, but if delayed for a few hours it may be too late. In cases of strangulated hernia and in acute glaucoma we have come to recognise the fact, that so soon as the nature of the disease has been diagnosed we are bound to relieve the constriction in the one case, and the tension in the other; so in acute inflammation of the bone, having determined the nature of the disease, not mistaking it for acute rheumatism of the joint, a free opening should be made into the part, the bone must be opened, and the focus of the inflammatory action reached, if possible, before suppuration has taken place in the osseous tissue.

An Esmarch's band having been applied to the thigh in a case such as that we are considering, a free incision is made through the soft tissues down to the epiphysis and along the shaft of the bone so as to expose the juxta-epiphyseal line. A trephine, about an inch in circumference, is then—with a light hand, so as not to splinter the bone—to be passed through the whole thickness of the tibia. Another incision is to be made through the soft tissues down to the point at which the trephine has perforated the bone, so that a passage is formed through the limb, including the small tunnel in the bone, from either end of which free drainage can take place outwards beyond the surface of the skin. The opening in the bone should be thoroughly and repeatedly washed out with mercurial solution, and then filled with iodoform, after which the limb, having been packed in antiseptic dressings, the elastic band may be removed from the thigh. As a rule neither drainage tubes nor sutures are required in these cases. The limb should be secured by an interrupted splint, so that the dressings may be changed without disturbing the parts operated on; in fact, the subsequent treatment of the case is very much that of a compound fracture. If pus has passed into the knee-joint it will be necessary to follow the treatment as regards the inflamed bone already described, and in addition to open the joint and wash it out with mercurial solution, treating it as we should do an acute abscess in any other part of the body.

The following case is an example of the results of the early treatment of acute juxta-epiphyseal osteitis.

T. E. J., aged 7 months, was admitted into the Westminster Hospital under my care on May 19th. She was a delicate little being, and suffering from whooping-cough. Thirty-six hours before admission into hospital, there being no history of any injury to the part, the child's right leg

became excessively painful and greatly swollen, the infant screaming whenever the infant the limb was moved. The child was at once taken to the hospital, and Mr. De Santi, who first saw the case in the out-patient department, ordered her into my wards, and that I should be sent for. Some four hours after admission the child's temperature was 104°, her right leg from the knee to the ankle was of brawny hardness and exceedingly painful. An incision was at once made down to the bone at the juxta-epiphyseal line of the upper end of the right tibia, and a tunnel made through the bone with a trephine; in fact, the patient was treated in precisely the manner already described. The child's temperature on the day following the operation had fallen to 100°, and the next day it was under that point. After three weeks the child was removed into the country, and two months subsequently, when I again saw her, all trace of the osteitis from which she had suffered had entirely disappeared, a result attributable to the fact of the diseased bone having been freely opened and washed out with mercurial solution and iodoform within forty-eight hours after the commencement of the disease.

TUBERCULOUS OSTEITIS.

Having described the conditions which render the marrow contained within the extremities of the long bones peculiarly liable to become the breeding ground of micro-organisms, it is unnecessary to enter further into the subject: the question we have to determine is, whether the chronic joint disease of childhood depends on tuberculosis of the marrow contained in the extremities of the bones entering into the formation of the affected joint. Unless we can satisfy our minds on this point, it seems almost impossible to arrive at any rational conclusions as to how we should best treat the early symptoms of such cases. The difficulty surrounding this question arises from the fact that pathological specimens of these joint affections in their early stages are seldom met with, and the osseous tissue is by no means an easy one in which to detect the presence of a few tubercle bacilli; moreover, in the early stages of these diseases of joints only a limited area of bone is involved, and within this area probably only a few bacilli exist.

During the past fifteen years, in the surgical wards of the Westminster Hospital, three children, while under treatment for the early stages of serofulous joint disease, developed tuberculous meningitis, and died. In these three cases (one a knee, and the other two hip-joint disease) we had an opportunity of examining the condition of the affected joints at quite the commencement of the disease. In the knee-joint case, a spot of inflamed osseous tissue was found at the insertion of the tendon of the extensor muscle to the tubercle of the tibia; in this congested portion of bone tubercles were discovered. In the two cases of hip-joint disease, in inflamed spots of bone near the circumference of the neck of the femur, on the distal side of the epiphyseal cartilage, distinct tubercles were found, and in these tubercles a few bacilli were detected. The ligaments, synovial membrane, and other joint structures, were very carefully examined, but no trace of tubercles was found in them. A somewhat extensive examination of specimens of chronic joint disease enables me to state that when the synovial or other joint structures are affected with tubercles, tuberculosis of the bone also exists; this remark applies to the more advanced stages of the disease, a subject upon which we cannot enter in this lecture.

My fellow student, Charles Price, as far back as the year 1865, from his own experience in excision of the knee-joint, arrived at the conclusion that disease met with in this articulation as a rule commenced in the ends of the bones. Volkmann was of opinion that strumous disease of joints commenced in the osseous tissue, and his opinion was to a great extent founded on his own observations of the early stages of joint disease. Ollier, and Gibney of New York, are of much the same opinion. Sayers has decided views as to the origin of these chronic joint cases in tuberculosis of the bones entering into the formation of the affected articulation. But we require further pathological evidence on the subject of tuberculosis of bone in the early stages of the joint disease of childhood. Such evidence as we have points to the presence of tuberculous osteitis as being the starting point of what are commonly called serofulous joint diseases. Pathologists, as a rule, further agree in considering that the outer layers of the cancellous tissue of the bone are the most frequently affected in the early stages of tuberculous osteitis. This fact, as already mentioned, is due in all probability to the marrow in this part of the bone being injured from the action of the tendons or ligaments on the osseous structure into which

they are inserted. In the acetabulum the disease not infrequently begins in the attachment of the ligamentum teres to the innominate bone. In other cases, from the pressure to which the soft structures in the deep layers of the articular cartilages are exposed, they become crushed against the plate of bone upon which they rest, and so form a favourable soil for the growth of tubercles. Bearing on the pathological evidence in favour of tuberculous osteitis being at the root of the chronic joint disease of childhood, we cannot overlook the fact that of all the joints of the body the spine is most frequently affected, the diseased action commencing in the cancellous structure of the bone in these cases. The same remark applies to the head of the first metatarsal bone, the os calcis, and the astragalus. Lastly, in all advanced cases of the chronic joint disease of childhood there is ample evidence of tubercles in the affected structures.

When the tubercle bacilli have found a favourable resting place in one or other of the tissues of the medulla of bone, they speedily become surrounded with layers of cells which protect them from leucocytes or other blood scavengers. Within this nest of cells the microbe multiplies, and its offspring produce either isolated, or it may be disseminated, tuberculosis of the surrounding medulla, and in the course of time the synovial and other joint structures are invaded by tubercle bacilli. Before the disease has advanced to this stage, and when, as in many cases it is certainly confined to the bone, is the time the surgeon may with the greatest advantage attack it in the hope of destroying the microbe which has started the mischief going on within the joint.

We may, however, approach this subject from another point of view. Without doubt a large majority of the cases of chronic joint disease we meet with can be traced back to an injury of some kind; nevertheless, in children injuries to the joints are incapable of causing chronic joint disease such as that which is seen so frequently in general hospitals throughout Europe. This is an important point, because if it can be shown that injuries in themselves are not a sufficient cause to give rise to the disease we are considering, it follows that in such cases there must be something beyond the traumatism to account for this slow but most destructive form of inflammation. Surgeons practising in all parts of India tell us they seldom, if ever, meet with cases of serofulous joint disease among native children in that country. These children, however, are subject to the same kind of accidents and injuries as Europeans; they are no better fed or housed than the corresponding classes in Europe, and yet practically they are free from these chronic joint affections which are so frequently seen in our hospitals, and which, from a pathological point of view, we have come to think depend on tuberculosis. In this way we are led to think that the tubercle bacillus is the something in addition to a traumatism which is necessary to produce chronic joint disease in childhood. But it may be argued, The tubercle bacillus exists in India; why should native children therefore escape tuberculosis of the joints? It is true this bacillus can live and thrive in India, but tuberculosis is certainly much less common in that country than it is in Europe; and we cannot overlook the fact that hereditary tendencies form an important element in a question of this kind. Beyond this, native children in India live day and night for the greater part of the year in the open air, and in much bright sunshine—conditions which, as we well know, exercise a vast influence on living organic matter; beyond this the native child has a cold bath every day. That sunlight, fresh air, and cleanliness have an important share in preserving living tissues from the inroads of certain forms of micro-organisms is apparent from the following, among other reasons. In the lower animals, such as monkeys, if left in their natural condition in tropical forests, we have no reason to suppose they suffer from tuberculosis; but if these same animals are confined in close sunless cages in our zoological gardens they die off in numbers from phthisis. Or, take another case, the children of our upper classes suffer little from chronic joint affections in comparison with their poorer brethren living in the dark dirty slums of our large cities. Physicians recognise the importance of fresh air and sunlight in the treatment of the early stages of phthisis and other tuberculous affections, with unquestionable advantage they order such persons an open-air life on

board ship during the summer, and a residence in the pure atmosphere of the higher Alps in the winter. The early stages of tuberculous testicle and of other glands seem to be amenable to similar treatment.

From a study, therefore, of the biological relation of the marrow contained in the ends of the long bones, from its physiological functions, and from the teaching of pathology, we are led to believe, as a rule, that chronic or serofulous diseases of joints are due to tuberculosis commencing within the cancellous tissue of the bones. Without question, such disease may and does begin at times in the deep layers of the articular cartilages; it may commence in the synovial or other soft structures surrounding a joint, but in the case of children we have no evidence to prove that such is the case, but rather the reverse.

Then comes the question, Can we fix on the site occupied by the tubercle bacillus in the early stages of joint disease? In cases of this kind there is always some tenderness over the whole of the joint; but if pressure is made with the tips of the fingers and thumb over the bones entering into the formation of the articulation, we come upon spots which are not only tender but which on pressure cause the child to cry out with pain. These painful spots are permanent; if we examine them to-morrow, or a week hence, there they are; and they indicate definite areas of tuberculous osteitis—the commencement of the disease—which at any moment may extend to the synovial or other tissues of the joint. Doubtless in instances of hip-joint disease in its early stages there is difficulty in ascertaining the precise position of tender areas of bone such as those referred to; the disease may commence in the acetabulum or beneath the articular cartilage of the head of the femur; but it most frequently begins in the neck of the bone, as in the two specimens already referred to, and it is because it begins in this locality and on the distal side of the epiphysal cartilage, that bacilli often extend down the shaft of the femur, and so, after excision of the head of the bone, the disease continues in the trochanteric portion and upper end of the femur.

In the early stages of tuberculous osteitis, as before stated, the symptoms are frequently referred to an accident or injury of some kind; the patient suffers from pain and stiffness of the articulation, and has difficulty in fully extending or flexing the joint without increasing the pain. On pressure over fixed points in the bones entering into the formation of the articulation, the pain is much augmented. These symptoms vary in intensity, but they persist for some weeks, and are increased if an effort is made to use the limb. Within a short period the patient's sleep is disturbed at nights by the spasmodic and painful movements of the limb. There may be little, if any, increase of the synovial fluid in the joint, but its temperature will be found higher than that of the sound limb.

The question then arises as to how we may best treat such a case, and this must depend upon the belief we hold as to the nature of the disease. If we believe, with many surgeons, that these chronic joint affections of childhood are in the majority of cases due to tuberculous osteitis, then it is certain we must direct our best efforts to destroy the tubercle bacillus which has found a breeding ground in the bones entering into the formation of the diseased joint. We had in India at one time a famous general who, with reference to a more substantial but hardly less dangerous form of being than we have to deal with, was wont to say: "When your enemies are in the open go straight at them, keep them moving; if entrenched go at them until you have turned them out of their position"—advice which we may with advantage apply to the case of the micro-organisms we are considering.

We are, however, bound to examine the opinion of surgeons who prefer less active measures in dealing with the early stages of tuberculous joint disease, and who hold that the best thing we can do in such cases is to lay the patient on his back in bed, with proper extension applied to the limb until the diseased joint can be flexed and extended without pain, and on pressure over the bones the patient no longer suffers from pain. Treatment of this kind always takes months, and may require two or three years before complete relief from pain is secured; even after so lengthened a period of treatment there can be no certainty that the

tubercle bacilli had ceased to exist in the previously diseased bone, and only waits a favourable opportunity to recommence its most destructive influence on the tissues. Beyond this we should hardly rest content with having nothing more in the way of treatment to recommend these patients than rest in bed for twelve months, and it may be two years and upwards, and that at the joyous period of childhood, a time when these little beings are overflowing with restless energy, and when constant motion seems almost necessary to a healthy development of body and mind. Nor can one help feeling, as in the case of the lower animals, that life under such unnatural conditions may predispose the individual to the attacks of various forms of micro-organisms. Further than this, surgeons in charge of our London and other hospitals throughout this country and the Continent have reason to believe that in many cases rest and extension are by no means all that could be desired in the class of cases that come under their care.

For instance, Mr. Howse, in his valuable paper published in *Guy's Hospital Reports* for 1892, has brought together the details of 130 cases of excision of the knee-joint in children treated by himself in Guy's and the Evelina Hospitals from the year 1875 to 1891. The cases are not brought down to a later date because, as Mr. Howse remarks, in a question of this kind it is all-important to ascertain the result of treatment some years after the patient has been "cured" according to our most misleading hospital nomenclature. One-half of the cases of excision of the knee joint operated on by Mr. Howse are stated to have been treated by rest, and many of them by extension for upwards of two years before excision of the joint was deemed necessary to save the limb or life of the patient. The other half of Mr. Howse's patients had been under similar treatment for less than two years, and yet their condition was such that this kind of treatment had to be given up and excision of the knee-joint performed. Do what we will in cases of chronic joint disease among the poorer classes of our larger cities, our efforts are in too many instances unsatisfactory, for many of these children suffer from the stain of hereditary disease which the hand of the surgeon cannot wipe away.

One of my former colleagues, Mr. R. Davy, was at one time rather fond of excising the bones entering into the formation of the knee-joint, both in the early and later stages of tuberculous disease. He was not at the time in the habit of employing antiseptics, and he adopted the open system of dressing wounds; no special care was taken to remove infected bone or other tissues. Nevertheless, most of these cases made admirable recoveries so far as the union of the diseased bones was concerned, and the cessation of the unhealthy action of the previously affected structures. There are, however, serious objections to excision of the knee-joint in children unless to save the limb or life of a patient, and under any circumstances this objection cannot be entertained as applicable to the early stages of the disease with which we are alone concerned at present. But one could not help feeling that the favourable results noticed in the cases referred to must have been largely due to the copious flow of blood which took place at the time and subsequently to the excision of the joint; the ends of the bones and surrounding tissues were thus flushed out and their embarrassed circulation relieved, so that the natural foes of the tubercle bacilli had an opportunity of going straight at their enemy. The subsequent free drainage through the open wound doubtless materially aided the salutary action going on within the tissues. By means of the trephine, however, we may not only secure free hemorrhage from the interior of the bone, but also make a tunnel through it which will ensure continued and efficient drainage, and further allow the free introduction of a germicide into the affected tissues. All this may be done at an early stage of the disease without running the slightest risk of inflicting any serious injury on the bone or soft tissues provided strict antiseptic precautions are followed.

Having given the reason and method of operating on bones affected with acute infective osteitis, it is unnecessary to make any further observations on the subject, except that a precisely similar proceeding should be carried out in cases of tuberculous osteitis in its early stages; before we have reason to think that caseation or caries of the bone has occurred.

Spots in the tender bones should be exposed, and a trephine of about an inch circumference employed, so as to remove one or more small columns of inflamed bone from the affected joint. After such an operation, the limb should be securely fixed to a splint, so that the dressings can be removed without disturbing the part; at the same time extension must be employed, and kept up for six weeks or so, after which we may omit the extension during the day and employ massage. In another ten days the patient should be placed under an anæsthetic, and complete flexion and extension of the joint carefully made. From that time gentle passive motion of the joint and massage should be employed daily, and the child, if possible, removed to the country and allowed to walk about, taking at first only gentle exercise, the amount and kind being guided by the freedom or otherwise with which the patient experiences from pain.

From considerable experience in the use of the trephine in the early stages of tuberculous osteitis, I am able to state with confidence that it is possible in not a few cases to cut short disease of the knee and other joints; and to prevent it spreading to accessory tissues entering into the formation of the affected articulation. Treatment of this kind may, without question, be carried through without running any risk which may not be safely undertaken, if the alternative is either caries of the affected bones or rest for long months in bed. It seems that as in life, so in operative surgery, we too frequently begin at the wrong end; if the experience we gain as we grow in years had been at our command at the commencement of our career, it would have been better for some of us and for many of our patients. And so with surgery, all our knowledge and skill should be applied to preventing and cutting short disease in its early stages; it is then that operative surgery may achieve its greatest triumphs. In this belief I have endeavoured to explain what seem to be the correct principles, and to deduce therefrom the line of practice to be followed in cases of acute infective osteitis in its early stages, and the far more common and hardly less mischievous tuberculous disease of the extremities of the long bones in childhood.

REMARKS ON THE EDUCATION AND TRAINING OF GIRLS OF THE EASY CLASSES AT AND ABOUT THE PERIOD OF PUBERTY.¹

By W. S. PLAYFAIR, M.D., LL.D.,

Professor of Obstetric Medicine, King's College; and Physician for Diseases of Women and Children, King's College Hospital.

In the few remarks I propose to make on my subject I do not, of course, aim at laying before you any novel matter. What I have to say is merely a little common-sense statement of general principles familiar to us all, but too often neglected. I have rather selected this subject as one which may possibly give rise to a discussion of interest, since it refers to matters constantly coming within the province of practitioners to whose charge the health of families is entrusted, and whose opinion on the questions raised may often be sought. We are all willing to admit, theoretically, that "prevention is better than cure"; practically we are apt to overlook prevention, and limit our efforts to cure. My object to-day is to insist on the endeavour at a peculiarly sensitive age in girls of so regulating their lives as to avoid sowing the seeds of mischief, which may, and often do, in future years develop into a disastrous crop.

What I think we ought especially to bear in mind is the highly sensitive nervous organisation of the human female, the development of the emotional element which distinguishes the woman from the man, and influences the character and progress of all kinds of disease in women, but much more especially diseases of the reproductive organs. Up to the time of puberty there is comparatively little difference between the sexes in health, in disease, or in any other condition. Conventionally they are separated, and different modes of education and training will soon make such difference as there is more marked, but boys and girls

¹ Read in the Section of Obstetric Medicine at the Annual Meeting of the British Medical Association, held in London, July-August, 1895.

will play together, work together, and so on, and are generally on a footing of perfect equality, there being little essential which distinguishes one sex from the other.

As soon, however, as the great function of menstruation is established, the sexual period of a woman's life begins, which must henceforth dominate her whole existence to a greater or less degree during the continuance of menstrual activity. The entire system now undergoes a marked change, the asexual child becomes a woman; her body shows the characteristic modifications fully described in all works on physiology and obstetrics, and with them are to be observed the not less important changes in character and in the general development of the nervous system which distinguish the woman from the girl. It is at this important time that the conduct of the health of the growing girl may influence for good or for evil the whole future of the woman. Judiciously managed, she may be so trained that she will be able to meet successfully the strain on the nervous system which she has so often to cope with in after-life, such as the duties of a wife and mother, or the struggle with domestic anxieties, worries, and sorrows which are rarely altogether absent from the lot of women. Injudiciously managed, as so many are at this important epoch, all these things which the strong-bodied and healthily minded woman may bear with no permanent bad results will tell terribly upon her. She will have no stamina, no power of resistance, and she may become the wretched broken-down invalid so often met with in the present day, especially in the upper ranks of life, in which the evil effects of unbalanced culture, and the bringing-up of girls like hothouse plants are so frequently seen.

These are my reasons for asking your attention to a few words on what should and should not be done in the education and training of girls before and after the establishment of puberty. This is all the more necessary since the higher education of women has taken such enormous strides of late years, so that it is now regularly recognised and is almost universal. Everywhere the so-called "high schools" for girls are to be met with, and the still more advanced colleges of the type of Girton and Newham are increasing in number, and are full of students. The old-fashioned girls boarding schools, with their perfunctory education and their elegant accomplishments, are driven out of the field, and a movement, which at first was scoffed and jeered at, has now gained the day.

Let me say at once that with limitations which are essential because of the question of sex, which cannot be got over, the movement is one which seems to me an enormous gain, and which I write of in no spirit of opposition. This statement is needful, since there is an unfortunate tendency on the part of many mistresses of high schools to listen to the warnings of medical men with incredulity, to accuse them of narrow-mindedness and opposition, which, as a matter of fact, the great majority of them are in no way guilty of. The recognition of and warning against possible evils are neither the one nor the other.

The one great fault which those who manage these educational establishments appear to commit is that they have started on the absolutely untenable theory that the sexual question is of secondary importance, that there is little if any real distinction between a girl between the ages of 14 and 20 and a boy of the same age.

I know of no large girl's school in which the absolute distinction which exists between boys and girls as regards the dominant menstrual function is systematically cared for and attended to. Indeed, the feeling of all schoolmistresses is distinctly antagonistic to such an admission. The contention is that there is no real difference between an adolescent male and female, that what is good for one is good for the other, and that such as there is is due to the evil customs of the past which have denied to women the ambitions and advantages open to men, and that this will disappear when a happier era is inaugurated. If this be so, how comes it that while every practical physician of experience has seen many cases of anæmia and chlorosis in girls, accompanied by amenorrhœa or menorrhagia, headaches, palpitations, emaciation, and all the familiar accompaniments of breakdown, an analogous condition in a schoolboy is so rare that it may well be doubted if it is ever seen at all? It is certainly not necessarily from work. The successes of women in the schools

have been so striking and numerous that their capacity for intellectual work cannot be doubted for a moment. One chief reason probably is that the male's work is safeguarded by an amount of physical exertion in the way of sports, which tends to keep him in health. It is true that in a few girls' schools attention has of late been paid to this point, but it is in a perfunctory sort of way at the best. There may be a gymnasium or some form of game, but while at a boys' school cricket and football are compulsory, to say nothing of the natural disposition of a boy to athletic pursuits, at a girl's it is merely optional, and if a pupil tending to ill-health avoids exercise little or no attention is paid to it.

As an evidence of this within the past week, I have been consulted in the case of two young ladies, aged respectively 11 and 16. One was chlorotic, and her menstruation had ceased for a year. On taking her time table at a well-known high school, I found she had 7½ hours of work, an amount not in itself, perhaps, excessive in a healthy girl. From 2.30 to 4 there were no lessons, and, if the weather permitted, she might if she liked take a walk, but it was not insisted on, and being naturally languid and listless, as all such cases are, she rarely did so. There was no other opportunity for exercise at all.

The other suffered from pronounced menorrhagia, anæmia, and debility. Her time table also was seven to eight hours, and she "occasionally took a walk."

In neither of these cases had the school authorities ever inquired into the state of an all-important bodily function which in both was very markedly aberrant, and yet, considering the paramount importance of such symptoms of impaired health in girls of these ages, it might fairly be held to have been part of the duty of those in authority in such schools to make the necessary inquiries which might have led to some alteration in the course of study or in her general mode of life.

While it is questionable whether in boys' schools the attention given to exercise and athletics may not be excessive, in girls' schools it is, on the other hand, not nearly sufficient. And yet this is a fault which might very easily be remedied. It would not be difficult to make games compulsory as they are in public schools for boys, and there are some which are admirably adapted for women, as, for example, golf, or rowing when it is feasible, or it may be by cycling. Each of these exercises the muscles generally, without those spasmodic efforts required in cricket, football, or even lawn tennis, which are, perhaps, too violent for girls. The results when well and freely used must be well known to all who have a knowledge of what a thoroughly healthy English girl may be. No better description of this could be given than that contained in a leading article in the *Speaker* on what the writer calls "the lawn tennis girl."

Sensible people have long ago agreed to accept this new type of womanhood as distinctly admirable. She has made her influence felt everywhere, both in real life and fiction. In real life we meet her in every country house, in every foreign hotel, and in almost every London square. And everywhere we meet her we come upon an excellent example of the healthy, well-developed, and well-balanced girl who does not think it necessary to devote herself to the study of her own anæmia, and who finds in a life of physical exercise an antidote to the mental fancies which are too apt to creep into the minds of the idle and self-indulgent.

This is an excellent description of a type we are all familiar with, and which, it is needless to say, we all admire. If high class educational establishments could succeed in turning out girls of this kind in larger numbers than they do at present they would do more towards lessening the number of neurotic women that the medical profession has to deal with than the medical profession can possibly do by any exercise of its own art.

One other regulation in girls' schools I should like to see made compulsory, and that is that no form of corset should be worn. The evils of these have so often been pointed out that it is needless to dwell on them in such a paper as this. Possibly in adult women the exigencies of dress and of custom make it hopeless to expect that more rational dresses should be adopted, and it may even be that in child-bearing women they have certain uses. In adolescent girls, however, who are still in *status puerilis*, nothing can be said in their favour, and it would be very easy for schoolmistresses to issue a sumptuary law prohibiting their use altogether.

It is an obvious corollary from what has been said that it is

the bounden duty of mistress, parent, and doctor at once to insist on the cessation of all severe study as soon as any of the physical signs of illness have shown themselves, such as it is impossible to be mistaken in, as, for example, chlorosis, amenorrhoea, or menorrhagia, wasting, complete loss of appetite, and the like, and yet this is not generally done. Quite recently I was consulted by a medical man, whose daughter was a pupil at one of the principal and best known colleges for girls. Her menstruation had ceased for a year, and she had lost over a stone in weight. On this account her father, as I think very properly, removed her, on which the head mistress remonstrated, and wrote saying that they considered the menstrual function was not of consequence, and that when it was in abeyance for a time it came all right afterwards, when the girls left school. Any theory more unphysiological and more likely to lead to subsequent shattered health in girls it would be difficult to imagine.

It is not work which, in my judgment, hurts, but the perseverance in work after Nature has hung out its danger signals, work in an unhealthy body; the attempt, in fact, to fight Nature. Then, indeed, the careless, prejudiced, or unwise mistress or parent may well find that "over-pressure," the very existence of which so many deny, is a stern reality, which may shatter the whole future of the girl.

ON SOME SUPERFICIAL AFFECTIONS OF THE RED PORTION OF THE LIPS.

[WITH A COLOURED PLATE.]

By W. ALLAN JAMIESON, M.D., F.R.C.P.E.,

Physician for Diseases of the Skin, Edinburgh Royal Infirmary, etc.

It is somewhat singular that disorders of the vermilion portion of the lips receive in general but scant notice in most works on dermatology. Some of these are not rare, while all are both annoying to the patient, and troublesome either by their obstinate tendency to recur, or by their intractability to treatment.

The best known of these is the common herpes labialis, so often met with in association with an ordinary catarrhal attack, or in some febrile conditions with the subsidence of the pyrexial symptoms, but occurring, also, quite independently of any such state. The patient, who is either quite young or at least under middle life, finds, rather suddenly, part of his lip swollen, perhaps hot and painful. The upper is more frequently attacked than the lower, and the same situation is prone to be implicated in successive seizures. On examination there may be only very slight redness, but if so there soon appear one or more groups of small vesicles seated on a swollen and reddened patch. These, if undisturbed, dry up in course of from three to six days into a brownish crust, or if disturbed too early, a weeping surface remains, to heal more slowly, and to occasion a thicker crust.

Should the weather be frosty, or a chill wind prevail, the lip is apt to become dry and chapped, as a result of the continual and involuntary moistening with saliva by the tongue, to replace the arrested secretion of the labial glands interrupted by the inflammation. In some districts infection from kissing is popularly blamed as a cause, possibly rightly in some instances. However this may be, the proclivity once induced, the ailment is liable to reappear at irregular and often inconvenient times. In both sexes it, like its congener herpes progenitalis, grows rarer as years advance, to cease finally at or soon after forty.

In treatment the administration of arsenic in small doses seems to control to some extent the repetition of the process, while locally painting the erythema or vesicles, as soon as they appear, with a film of flexible collodion, checks the further progress and expedites the cure. In those of the male sex the protection of the beard and moustache when worn is a valuable prophylactic.

Another and more troublesome affection of the lips is the formation of a small though deep and painful fissure in the centre of the lower lip, where the two halves from which it is developed become fused into one; or at the angles of the mouth, or, but less commonly, in the upper lip, on either

side of the central portion of the three parts, from the coalescence of which it is formed. Those in the centre of the lower lip and in the upper are seen usually in women, and the cause is, at least sometimes, the bad habit of biting and dragging the thread before passing it through the eye of the needle. Those at the angles of the mouth occasionally own a syphilitic origin. They are often accompanied by a sort of intertrigo, the surface in their neighbourhood is soddened, and may even pour forth a degree of purulent secretion. The treatment of the fissures in the centre of the lip consists in scraping the whole surface carefully but thoroughly with a fine curette; then when the bleeding has ceased, having approximated the edges by pressure, a film of salicylic wool is placed on, and secured in place by painting over with flexible collodion. Great care must be enjoined to avoid stretching the part till firm union has been secured. Thus a very small spoon should be used, the morsels introduced into the mouth must be restricted in size, while fluids ought to be imbibed through a feeding cup. Those at the angles of the mouth, if antisyphilitic remedies are not called for, can usually be cured by cleanliness and the employment of an antiseptic ointment, such as 10 grains of salicylic acid in 1 ounce of cold cream.

Eczema limited to the exposed portions of the lips is comparatively rare. The best account is that given by Besnier and Doyon.¹ In one of the few instances which have come under my notice, the patient was a girl, aged 8, sent to me by my friend Dr. Underhill, in the end of October, 1893. The eruption tended to recur every winter. There was a thinly-crustated patch on the left side of the lower lip. The child was at the time somewhat pale. Another was a young lady, anemic, though with some colour in her cheeks. She lived in the country and had a good appetite, but the bowels were constipated, and the periods were irregular. She had suffered for seven years from the complaint. Both lips were covered with thick yellowish crusts. The lips themselves were swollen, and felt painful when she was in a warm room, and were extremely tender to contact with any hot substance or fluid. At times there was considerable suppuration, and the lips became so stiff as to be nearly immovable. In both cases cure, apparently permanent, was accomplished by softening and removing the crusts by aid of boracic starch poultices applied cold. Strips of Unna's zinc ichthyol salve muslin were closely and constantly laid on at night, the salicylic cold cream already mentioned repeatedly smeared on during the day, and iron prescribed for internal use. It seems doubtful if eczema of the seborrhoeic type alluded to by Besnier and Doyon, and well described by Dabreuilh,² ever occurs on the lips alone.

The case represented in the coloured illustration is a peculiar one, and though it bears a considerable resemblance to eczema, yet the careful investigation into its morbid anatomy made by Dr. Leith, pathologist to the Royal Infirmary, brings it into closer association with epithelioma.

B. S., aged 33, a Jew, native of Russian Poland, but employed in Edinburgh as a tailor in rubber works, was admitted to Ward 37 on June 26th, 1895. Though pale in complexion he had suffered from no ailment save an attack of piles six years previously. There was no history or suspicion of syphilis. His family was apparently vigorous, as his father (80) and his mother (85) were well. He was himself a great smoker of cigarettes till his lip was affected. The complaint began three years since, on the left side, as a scaly spot. This continued much the same for two years, then it extended, and the whole lower lip has been involved for the last seven months. The lip was swollen to double its normal size and everted. Its extremelower edge for about an eighth of an inch in the centre appeared healthy; then there was a white cicatricial condition on each side of the lip close to the skin margin. The central portion was partly reddish and granular, partly covered with dirty yellow crusts, partly cicatrised, the scar being soft, white, and tender. The inner surface showed a whitish pellicle over the red mucosa, becoming gradually lost towards the gums. The gums themselves, particularly the interdental prolongations, were swollen and fungating. The lower teeth were brown and en-

¹ Kaposi, *Verh. d. Ges. der Anat. u. Physiol. de la Peau*, Traduction Française 1891, T. 1, p. 694.
² *Annales de Derm. et de Syph.*, 1892, p. 221.

TO ILLUSTRATE DR. ALLAN JAMIESON'S PAPER.

crusted with tartar. At times pain of a darting character was experienced in the lip, or a sensation of burning. The surface bled readily. The treatment consisted in the first place of the application of borie starch poultices till the lip had been thoroughly cleaned from all accretions. It was then cauterised with 50 per cent. lactic acid in water, the acid being pressed firmly in with a swab of cotton wool, and subsequently dressed for some days with zinc ichthyol salve muslin, when the cauterisation was repeated. This occasioned considerable pain, but the appearance improved very materially. He was made an out-patient, and instructed to protect the still tender surface by investing it with a film of salicylic wool painted over with flexible collodion. In October there were no longer any crusts; the central part had a roughish and granular aspect, though everywhere there was an epidermic covering, and it could be handled without causing pain but it was still swollen to some extent. When he was admitted, a wedge-shaped portion of the lip was cut out from the left side, placed in corrosive, and from this vertical sections were made by Dr. Leith, who thus reports on it:

1. *The Epidermis*.—This formed an even and unbroken layer upon the surface: (a) The stratum corneum was slightly and somewhat irregularly thickened; (b) the stratum granulosum was fairly normal; (c) the stratum Malpighii was well developed, its interpapillary processes varying in length and thickness. Several of these were branched at their ends and sides, a few slender processes dipping rather deeply into the dermis. The cells of the germinal layer mostly showed a separation from one another, with well-marked prickles, or, in some cases, larger branched, filamentous, processes. Some were roundish, oblong, long, flattened, or of irregular shape. Further out the cells were mostly very large, with large nuclei, containing one or two large nucleoli. A few here and there had lost their nuclei, and their protoplasm stained badly, an appearance not unlike an early stage of colliquative necrosis. The lymph spaces everywhere between the cells were notably very large, were crossed by faintly stained prickles, and here and there contained leucocytes. At one or two places there was an appearance suggestive of a slight colloid degeneration of a cell or cells.

2. *The Dermis*.—This was extremely cellular, due to a leucocyte infiltration, shown abundantly everywhere except in that part just superficial to the orbicularis muscle. The blood vessels of the papillae were of normal calibre, but no nerves could be detected. A few of the papillae were encroached on at their apices and sides by ingrowths from the stratum Malpighii. There were at least two small islands in the substance of the dermis, containing active-looking epithelial cells, with evidence of invasion of the rete by an upgrowth from the dermis. Nowhere could any trace be found of the minute racemose labial glands which lie between the epithelium and the muscle.

3. *Muscle*.—The muscular fibres were practically normal. Their lymph spaces were, however, somewhat enlarged and were crammed with leucocytes, which were also seen in small numbers here and there between the fasciculi.

On these pathological appearances Dr. Leith makes the following remarks: "There were here essentially only three abnormal conditions: (1) great enlargement of the lymph spaces, with oedema; (2) a moderate overgrowth downwards of the stratum Malpighii; (3) an abundant small round celled infiltration of the dermis. As a deduction from these, only two classes of lesions suggest themselves to which the disease of the lip seems allied, namely, (a) a true dermic inflammation of a chronic nature, secondary to the epidermic changes, and (b) a mild form of epithelioma; if the former, it shows nothing distinctive of the kind of inflammatory process present, such as tuberculous—neither tubercle bacilli nor any other micro-organisms were found—syphilitic, or otherwise. The marked oedema is a noticeable feature, which, so far as the sections indicate, is not accounted for by any widespread obstruction to the lymphatics or the veins. The moderate downgrowth of the stratum Malpighii is not inconsistent with the inflammatory nature of the lesion, as even more pronounced proliferation of the interpapillary epithelium is frequently noticed in various forms of chronic inflammation in the dermis. At the same time, it is impossible, after a careful consideration of the sections, to shut out the probability of the second alternative, namely, that the

disease is primarily epitheliomatous in its essence. The appearances undoubtedly point to a primary epidermic affection. The local well-marked thickenings of the corneous layer suggest a form of psoriasis, but this is not supported by the other characters nor by clinical evidence. A diffuse or spreading variety of papilloma might be surmised, but many of the appearances are not consistent with this disease. It is much more probable that it is a form of epithelioma. The long, slender epithelial processes invading the dermis here and there, the small islands of epithelium found in it, support this opinion. The appearance of early colloid degeneration is significant of imperfect cell nest formation, while the small round celled infiltration of the dermis is characteristic of epitheliomata."

The conclusion arrived at by Dr. Leith from the microscopical examination is the same as that drawn by myself from the clinical aspects. The case in many particulars resembles one already briefly recorded by me as an example of epithelioma,³ though the diagnosis was not confirmed by any biopsy. Certain very superficial epitheliomata of the skin can spontaneously cicatrise, or are curable by mild treatment, just as some instances of cutaneous tuberculosis may heal though uninterfered with by curative methods—and *sponte*, in fact. How far the relief afforded in B. S.'s case may be lasting, or whether a deeper or more active form of disease may eventually supervene, time only can determine.

The case in recent literature which bears the closest similitude to it is that of chronic exfoliating inflammation affecting the lower lip, related by Dr. James Galloway.⁴ In his case, however, there was a tendency to seborrhoea of the face and scalp, absent in mine. It differs also from the cheilitis glandularis of Volkmann and Purdon,⁵ since in the latter there was

Fig. 1.—Microphotograph of vertical section × 25. The irregular thickening of the cutaneous layer, the ingrowths from the stratum Malpighii and the leucocyte infiltration, can be readily made out. The break in continuity towards the upper right is accidental.

distinct evidence of hypertrophy of the labial glands.

The coloured plate shows the appearance of the lip previous to the institution of any treatment. The epidermic accumulations, the granular surface, and the oedematous swelling are all visible.

Other occasional disorders of the lip may occur. Small warty growths may form. Such generally appear on the lower lip. They are annoying from their presence, and may long remain superficial, analogous in that way to the warty

³ *Journal of the Royal Society of Medicine*, 1894, p. 342.

⁴ *Brit. Jour. of Dermatology*, 1895, p. 117.

⁵ *Ibid.*, 1893, p. 23.

stage of rodent ulcer. In the end, however, such warts on the lip are apt to degenerate into deeply penetrating epitheliomata.

Vascular growths may form on the lip, usually assuming the form of venous naevi, dark purplish, soft prominences, of the size of half a pea or larger. They are not very uncommon on the underlip of elderly women, cause no subjective sensations, but are disfiguring. They can be dealt with very satisfactorily by electrolysis.

Fig. 2.—Microphotograph $\times 100$. One of the slender epidermic processes invading the dermis, the abundant small, round celled infiltration, even the enlarged lymph spaces, are perfectly brought out. At the lower part, to the right, is seen one of the epithelial islets.

One instance has come under my notice where the little tumours of molluscum contagiosum occurred on the proboscium. They were not limited to that region, and if the view be accepted that the ailment owns a glandular origin they may have taken their rise in the labial glands.

ON A PREPARATION OF MILK FOR DIABETIC PATIENTS.

By SYDNEY RINGER, M.D., F.R.S.,
Physician, University College Hospital.

THE extremely meagre and distasteful diet of diabetic patients induces me to draw attention to a preparation of milk which I hope may be found useful and not distasteful.

In the *Journal of Physiology*, vol. xi, p. 473, and vol. xii, p. 164, in recording experiments with caseinogen and casein, I drew attention to a method of preparing caseinogen from milk, which is freed from all sugar (and salts). The following is the method: Add to a pint and a half of milk about 90 c cm. of a 10 per cent. solution of acetic acid. This precipitates a curd-caseinogen. It should be allowed to settle, and the clear fluid siphoned off and distilled water added. After settling, this should be decanted or siphoned off, and the curd should be filtered and well washed with distilled water. If it is then rubbed up in a mortar with some calcium carbonate, and water is added, and all the caseinogen becomes dissolved, the calcium carbonate soon settles and the milky fluid can be decanted off. The dissolved caseinogen behaves just like milk. If rennet and a calcium salt is added, and the mixture is heated to 40°C ., it quickly clots, the caseinogen becomes changed into casein, which precipitates by combining with the calcium salts.

My friend, Mr. Martindale, with the aid of his able labora-

tory assistant, Mr. Lee, has lately made some of this solution of caseinogen, or in other words, milk without the sugar of milk. They find that the caseinogen settles better after the addition of the acetic acid if the milk is diluted with an equal quantity of water, and they filter and wash the precipitated caseinogen on a coffee filter, which allows the washing to be made quicker than in my experiments where I used filtering paper.

On the addition of about 2 per cent. of glycerine to the mixture of caseinogen a not unpalatable form of milk is produced.

THE RED LIGHT TREATMENT OF SMALL-POX.

Copenhagen.

HISTORICAL.

THE method here treated of, which is the result of half-forgotten empiric experience and modern scientific investigations of light, is of considerable medico-historic importance. In the Middle Ages small-pox patients were treated by wrapping them in red coverings and by putting red balls in their beds. John of Gadesden treated a Prince of Wales for small-pox by surrounding him with red objects. According to information which has appeared in connection with the new red light treatment, red is as yet much employed in different places in the popular treatment of small-pox. In Roumania, according to Dr. Capitanowitz, the small-pox patient's face and hands are covered with red cloths; Dr. Lassabatie informs us that in Tonkin the patients are placed in alcoves which are closed with numerous red carpets, whilst Dr. Sassakawa reports that in Japan the patients are covered with red blankets, and children with small-pox are given red toys.

This remarkable and uncertain employment of the red colour in the treatment of small-pox has naturally been looked upon as a mediæval superstition, but the numerous new experiments which proved the importance of the red light treatment must undeniably lend them something more than a historic interest.

Whilst engaged upon some investigations as to the effect of light upon the skin, my attention was drawn to some old reports (Pieton,¹ 1830, Black,² 1867) on the favourable results arrived at by the exclusion of light in cases of small-pox. As everything, from a theoretical point of view, was in favour of the correctness of the observations, and as at the same time practical experience proves that the pock-marks are thickest on the face and hands—that is, those parts of the skin which are most exposed to the light, I drew (without having any knowledge of the mediæval treatment) attention in an article in *Hospitalstidende*, July, 1893, to this treatment, but proposed at the same time the use of red light instead of complete darkness—that is to say, the exclusion of the light's chemical rays. Shortly afterwards this modified treatment was tried in Bergen (Norway), where Drs Lindholm and Svendsen³ treated 8 patients in red light. Of these 8, 4 were unvaccinated children, of whom some had confluent small-pox; they were all cured without suppuration, without secondary fever, and without pitting.

These favourable results, and the explanation which I had given at the same time led to the method being tried in various places. Before proceeding to the reports which have appeared on the subject, I purpose giving a short theoretical account of the effect of light upon the skin, which is of course the basis for an understanding of the method.

THE EFFECTS OF LIGHT ON THE SKIN.

It has for a long time been a recognised fact that sunlight can produce an irritation of the skin of a greater or less intensity, from a slight erythematous redness to the formation of vesicles, and desquamation (erythema or eczema solare). It was formerly believed that this was caused by the heat rays, and the erythema was therefore called erythema calori-

¹ On the Exclusion of Light as a Means of Preventing the Pitting in Small-pox; the *American Journal of Medical Science*, 1832, p. 119.

cam. More recent investigations (especially by Charcot,⁴ Widmark,⁵ Unna,⁶ Hammer,⁷ Maklakoff,⁸ Robert Bowles,⁹ and myself¹⁰) have proved that the inflammation is not due to the solar heat rays but to the most refrangible, the so-called chemical rays. This also explains various practical observations. For instance, when climbing glaciers, even when the temperature is below freezing point, the skin is liable to light erythema, which is principally due to the strong reflection of the light from the ice fields. Very strong electric light, such as that produced by the electric welding of metals, can cause a severe inflammation of the skin and of the mucous membrane of the eye, which is much more violent than that caused by solar light. The Russian physician, Maklakoff, who exposed himself to this influence of light, describes the phenomenon as follows:—All those parts of the skin which were exposed to the light became severely inflamed, the face was brick red, swollen and painful, the skin of the eyelids baggy so that it was impossible to open the eyes. After two days had elapsed the symptoms improved, and a few days later the skin peeled off in large flakes, as after scarlet fever.

The inflammation of the skin caused by the chemical rays of light differs macroscopically from that caused by heat, inasmuch as it appears from a couple of hours to half a day after the exposure, whilst, as we know, a burn appears at once; further, it is followed by a pigmentation of the skin. Microscopically it differs, as I have proved by experiments on tadpoles,¹¹ from all other forms of inflammation, inasmuch as the red blood corpuscles are much contracted.

Erythema solare is most frequently observed in the spring and in fair persons—that is, when the pigment of the skin is impoverished. The pigment of the skin is, in fact, principally a defence against the inflammatory influence of the chemical rays, and we are doubtless right in supposing that this is still the principal reason for the negro's blackness, and for the circumstance that the skin of the different races becomes darker the nearer we approach the equator.

It will then be seen that the chemical rays are capable of producing an inflammation of the skin, and that Nature finds it necessary to protect even a healthy skin against these rays; it is, therefore, not surprising that when diseased, as for instance in small-pox, the skin requires still more protection. This protection is best and most pleasantly given by excluding the chemical rays, as I have recommended, and allowing the light to be filtered into the patients' room through red glass or red curtains.

It is curious to observe that many of the methods which have been employed to prevent pitting in small-pox have had as a main feature the exclusion of light, and in all probability their utility has been due to this circumstance. I may mention painting the skin with tincture of iodine, with strong solutions of nitrate of silver, and in particular the covering of the face with a mask, or with compresses. Great stress has been laid upon the fatty substance or other matter with which these compresses should be impregnated, but this question is of secondary importance, the main point being the exclusion of light. Various authors, among others Stokes,¹² have observed that scars were formed only where the mask or compress left the face uncovered, but not where the skin was entirely covered. Stokes was of opinion that this was owing to the action of air upon the skin; his observations were excellent and correct, only he attributed to air what was due to light.

The objection may be brought forward that the faint light which comes into a sick room would not be sufficient to cause an inflammation of the skin or to increase the inflammation already present. To this we can reply that the skin in certain cases and under certain circumstances is remark-

ably sensitive to the influence of the chemical rays. There are many accounts of such particularly sensitive skin; for instance, Velel¹³ mentions a lady whose skin was so sensitive that even when sitting in her room the side of her face nearest the light became slightly inflamed. Velel advised her to wear a thick red veil with favourable results.

Another interesting circumstance is that cattle and sheep, which have eaten buckwheat get an eruption when they stand in the sunshine or ordinary light, but not when they stand in dark sheds. This is known to farmers, and has also been made the subject of scientific investigation by Vlchow and Wedding.¹⁴ It is interesting to learn that it is only light-coloured cattle which are subject to the inflammation, not the pigmented, and a white cow which Wedding tarred on the one side did not get the inflammation on that side, but only on the other. This is another good example of the protective qualities of pigment.

It is, then, evident that ordinary daylight can produce an inflammation of the skin where there was none previously. It is, therefore, much easier to understand that ordinary daylight can increase an inflammation already existing, as is the case in small pox.

RESULTS OF THE USE OF RED LIGHT IN SMALL-POX.

After the favourable results of Lindholm and Svendsen mentioned above had been published, the method was tried in various places, and there are already numerous reports on the subject from the following various authors: Feilberg¹⁵ (Copenhagen), Benckert¹⁶ (Göteborg), Strandgaard¹⁷ (Amsger, Denmark), Krohn¹⁸ (Helsingør, Denmark), Mylius¹⁹ (Nakskov, Denmark), Oettinger²⁰ (Paris), and J. W. Moore²¹ (Dublin). The results obtained by all these authors²² have been extremely favourable. The total number of patients treated by them was about 70, and the method failed in only one case (Benckert).

It must be observed that these reports are of considerable value, as the authors as a rule were evidently exceedingly sceptical before they had tried this strange method. Some few of them have confined themselves to mere reports of the history of the cases, and have otherwise been extremely reserved in their expressions of opinion; some (Feilberg, Svendsen) have for certainty's sake made controlling experiments; others (Oettinger, for instance) chose the most severe cases to experiment with.

CASE.—The illustration on p. 1414 shows the condition of the face of O. B., aged 48, on the eighth day of the disease. She was treated in the Copenhagen Small-pox Hospital, and was kept in red light from the third to the twelfth day of the disease. She was discharged twenty-four days after the day on which the photograph was taken, and then did not present any pitting whatever. The temperature chart, which is also reproduced, shows that there was not any secondary fever whatever.

By comparing these reports and the results obtained, the following view of the action and importance of the treatment will be obtained: When the patients come under treatment early enough—before the fourth or fifth day of the disease—suppuration of the vesicles, even in unvaccinated persons and in cases of confident small-pox, will be avoided—I exception out of about 70; as a rule, the secondary

fever does not appear, but even when it does the temperature is lower and the fever of shorter duration than is usually the

Case of small pox; Treated in Red Light; no subsequent pitting.

case. As a result of the absence of suppuration the disease becomes of shorter duration and less dangerous, as the greater number of complications do not show themselves; further, the patient escapes pitting. Some authors have observed "minute scars" on the nose and fingers in some few cases; but this only proves that what are generally known as "pock marks" are done away with. It would seem that children—perhaps on account of their fine epidermis—are more completely exempted from scars than adults. It must, however, be mentioned that this treatment does not prevent the skin becoming hyperæmic where the vesicles have been; the hyperæmia, however, disappears after six to eight weeks, and it is then impossible to see that the person in question has suffered from small-pox.

From the above it is evident—so much so that I need hardly point it out—that this treatment is only a skin treatment; upon the infection itself it has no influence, or at least so slight a one that it is not worth noticing. Should the patient come under treatment after the fifth day of the disease, it is uncertain whether the suppuration can be avoided; sometimes this is the case, sometimes not; but it would appear that in such cases the treatment renders the suppuration less severe and less malign. Some authors (Feilberg) advise the use of the red light even when the suppuration is commencing.

METHOD OF CARRYING OUT THE TREATMENT.

As far as the carrying out of the treatment is concerned, the following main points must be noticed:

1. The exclusion of the chemical rays must be absolute; even a brief exposure to daylight may produce suppuration and its sequelæ. In other words, the skin during small-pox is as susceptible to daylight as a photographic plate, and must be kept from the chemical rays in the same way and almost as carefully. If, therefore, red window glass is employed, it is necessary for it to be of a deep red colour, and if curtains are used, they must be very thick or in several layers. When the patient takes his meals, or during the physician's rounds, artificial light—for instance, faint candle light—may be used without any danger. As even a brief exposure to daylight can produce suppuration, and as this treatment is somewhat burdensome for the nurses, so that they are often tempted to draw back the curtains, it is necessary when they cannot be depended upon to take care that the treatment is carried out correctly, for instance by nailing the curtains.

2. This method does not prevent but allows the employment of any other treatment which may be considered necessary.

3. The treatment should be commenced as early as possible; the nearer the commencement of the suppuration the smaller the chance of success.

4. The patient must remain in the red light until the vesicles have dried up.

A CASE OF MYOMATA OF THE UTERUS, WITH PREGNANCY OF FIVE MONTHS' DURATION: TOTAL EXTIRPATION OF UTERUS AND TUMOURS: RECOVERY.

By MURDOCH CAMERON, M.D.,

Professor of Obstetrics and Gynecology in Glasgow University;
Physician for Diseases of Women, Western Infirmary.

THE following case is of interest from the rapid development of the tumours during pregnancy, and the almost complete obstruction of the parturient canal caused by them:

Mrs. C., aged 36, was admitted to the Western Infirmary under my care on July 16th, 1895, complaining of great distension of the abdomen. The patient considered herself about five months pregnant, but as the abdomen was so much distended she consulted me regarding her condition. She stated that she had always enjoyed the best of health until the spring of the present year, that menstruation commenced at the age of 15 and continued perfectly normal and regular until February, 1895, that she had been married for

about two years, and had had no children and no miscarriages.

About eight years ago the patient noticed for the first time and quite by accident a swelling in the left iliac region. It was about the size of a hen's egg when she first felt it. For a month or two it increased in size slightly, then ceased growing and remained stationary until she became pregnant at the end of February. On February 19th she menstruated for the last time. Three or four weeks after she began to be troubled with morning sickness, and about the middle of June she felt foetal movements for the first time. She was quite satisfied that she was pregnant; but what troubled her was the fact that her abdomen became so rapidly distended. It was, however, during the six or seven weeks previous to her admission into hospital that the distension seemed to increase most rapidly.

Her general condition on admission was not very satisfactory. There was great oedema of the legs and thighs but apparently no ascites. There was some dyspnoea. The mucous membranes were of a good colour. She had no difficulty in passing urine but her bowels had been very constipated. There was nothing abnormal in the lungs and heart; milk could be expressed from both breasts. The abdomen was much distended, presenting the appearance of a pregnancy at full time. It measured 37 inches at the level of the umbilicus. On palpating the abdominal tumours, a large smooth, round, hard swelling was found to occupy the left side. It crossed the middle line, and was continuous with a swelling on the right side, from which it was separated, however, by a sulcus. This swelling on the right side was elastic in consistence, but two or three hard rounded nodules could be distinctly made out upon its anterior surface. The uterine souffle could be heard over it, but no foetal heart sounds could be recognised.

On vaginal examination, the whole cavity of the pelvis was filled up with a hard mass firmly impacted into it, and continuous with the tumour above. So completely did this tumour block up the pelvic cavity that the forefinger could with difficulty be passed up the vagina. The uterus appeared to be very much drawn up, as the examining finger could not reach the os externum.

On July 19th, the patient was examined under chloroform, but nothing further was made out.

On July 22nd abdominal section was performed. On opening into the abdomen a large irregular tumour was met with, the left portion consisting of an interstitial myoma, the right of the distended uterus. In addition, implanted on the upper and posterior uterine walls, were several subserous myomata, varying in size from a walnut to an orange. Having made an incision through the anterior wall, a foetus of 8 months was removed. It was perfectly formed, and had evidently only quite recently died. The placenta was well developed, and was easily detached. An elastic ligature was passed round the uterus and tumours as close as possible to the cervix and secured, after which the uterus with the tumours were cut away. The uterine and ovarian arteries could now be more easily reached and were ligatured. The ovaries and tubes were also removed. The tumour blocking up the pelvis was with some difficulty drawn up on account of impaction and adhesions. Having enucleated this mass of tumour nothing remained but the cervix, which was also separated from its connections. The peritoneum was stitched round and round with catgut ligatures to the mucous membrane of the vagina. These ligatures were then drawn down into the vaginal canal by means of a pair of long forceps passed up into the abdomen through the vagina. The abdominal wound was then closed with silk worm sutures; no drainage tube was used. The parts removed weighed 27 lbs.

The patient made a good recovery. She had a little sickness on the third and fourth day, when the temperature thrice registered 100° F. After that it never rose above 100°, and fell to normal after the ligatures were discharged from the vagina on the tenth to the twelfth days. She left the hospital in the seventh week after the operation perfectly well.

A POST GRADUATE School of Medicine has recently been founded in Washington, where it is said to be much needed, as there is no school of the kind south of New York and Philadelphia.

THE TREATMENT OF MALIGNANT TUMOURS BY THE TOXINS OF THE STREPTOCOCCUS ERYSIPELÆTIS AND BACILLUS PRODIGIOSUS.

By JAMES SWAIN, M.S., M.D. LOND., F.R.C.S. ENG.,
Assistant Surgeon to the Bristol Royal Infirmary.

THE treatment of inoperable malignant disease has hitherto proved so hopeless that it is not to be wondered at that we have been slow to believe that any remedy can do good in such cases, and that therefore the method indicated by the title of this paper has scarcely received the attention it deserves, although in proportion to the hopelessness of the case we should be glad to welcome any gleam of hope.

Malignant tumours have been known to disappear occasionally after the patient affected had suffered from an intercurrent attack of erysipelas, and when Fehleisen¹ made the important discovery that he was able to produce a factitious erysipelas by inoculating pure cultures of the streptococcus erysipelætis, he applied this knowledge to the treatment of malignant disease. Although only 1 of the 6 cases which he inoculated was reported as being well six months after inoculation, other inquirers were stimulated to work in the same direction, and Bruns,² Kleeblatt,³ Coley,⁴ and others have published cases in which an accidental or factitious erysipelas has exerted a beneficial or curative effect in cases of malignant disease. Sarcoma has generally been more amenable than carcinoma, and Bruns, in his record of 14 cases of malignant disease associated with erysipelas, found that of 5 cases of sarcoma in which the diagnosis was confirmed microscopically 3 were permanently cured.

Coley⁵ has collected 38 cases (including his own) of malignant disease, in which erysipelas occurred either accidentally or intentionally. "Of these 38 cases the erysipelas occurred accidentally in 23 cases, and was the result of inoculation in 15 cases." Seventeen cases were carcinomata, of which 3 (17.6 per cent.) were cured and 1 (5.9 per cent.) died; 17 were sarcomatous, of which 7 (41 per cent.) were cured, and 1 (5.9 per cent.) died; 4 were either carcinomata or sarcomatous, of which 2 were cured. "Grouping by themselves then the cases where the erysipelas was artificially produced, we find 7 cases of carcinoma, 1 cure or 14.3 per cent., and 8 cases of sarcoma, 2 cures, 25 per cent." From these figures it appears that a factitious erysipelas has not been attended with such good results as regards disappearance of the tumours as an accidental erysipelas.

The reaction following inoculations (for Coley repeated them in the same patient) usually subsided in 36 to 48 hours, unless a definite attack of erysipelas was produced; but as the effect on the patient and the tumour was much the same in either case, Coley argued that the effects must be due to the toxic products of the streptococci rather than to the active development of the organisms themselves, and he therefore determined to experiment with filtered cultures. "The germs having been removed by means of a Kitasato filter, without subjecting the filtrate to heat."

Roger's⁶ researches pointed in the same direction, but he further found in experiments upon rabbits that the bacillus prodigiosus has the power of intensifying the action of the streptococcus erysipelætis, and therefore the toxins of the two germs were mixed—the filtrate in each case being obtained by means of a Kitasato filter as already explained. The advantage of using these filtrates, if successful, lay in the fact that the danger of an attack of erysipelas would be removed, and that isolation of the patient would not be necessary.

This was a great advance, and Coley⁷ confirmed the fact that the mixed toxins had a more beneficial effect than when used singly, and also found that in a certain proportion of cases (only 4 out of 10) the tumours disappeared. He subsequently thought that the filtration method failed to utilise anything of value in the bodies of the organisms themselves, and he therefore prepared the toxins "by subjecting the cultures to the lowest temperature (25° C.) that would suffice to destroy the germs." In this way Coley⁸ has treated 13 sarcomata, with 3 cures, and 11 carcinomata with improvement only; or,

counting all cases of sarcomata in which the mixed toxins have been used, we find 38 cases with 9 cures.

The toxins prepared in the way last stated represent the present method of dealing with these cases. I am aware that Coley² has treated several cases with blood serum obtained from animals inoculated with the two organisms under discussion, but I am informed by my friend Dr. Parker (Clifton) that Dr. Coley has told him that the results are unsatisfactory.

The following is a brief record of a case which I treated unsuccessfully in this way, the toxins being obtained from America, where they had been prepared according to Coley's directions.

G. K., aged 48, had the right upper jaw removed on April 10th, 1894, for malignant disease. Microscopical examination of the growth showed it to be round-celled sarcoma. On December 3rd, 1894 he again came under my care with a recurrence, and the remainder of the malar bone and part of the zygoma were removed.

On June 2nd, 1895, he was admitted to the Bristol Royal Infirmary for the third time. There was then a large recurrent sarcomatous growth occupying the whole of the right cheek, and extending into the orbit and towards the base of the skull. There were enlarged lymphatic glands in front of the right ear, in the right submaxillary region, and at the angle of the jaw. There was also a secondary subperiosteal deposit in the frontal region immediately above the root of the nose.

On June 3rd, injections with the toxins were commenced and continued until July 9th. In all the patient had twenty-eight injections, which at first were given daily. The quantity of injection used was gradually increased from $\frac{1}{2}$ up to $\frac{1}{2}$ xvij, according to the effect produced. The first eleven injections were given either under the healthy skin, or into the affected cheek or glands. $\frac{1}{2}$ ij into the cheek was the smallest dose which produced a rise in temperature, but as no temperature reaction followed the injection of $\frac{1}{2}$ vij under the healthy skin, all the later injections were given either into the affected cheek or lymphatic glands. The maximum temperature recorded was 103.8° F. Rigors frequently followed the injections. The details are as follows:

June 4th. $\frac{1}{2}$ ij injected into affected cheek. One hour afterwards complained of feeling cold but there was no rise of temperature.

June 5th. $\frac{1}{2}$ ij injected into gland in front of ear, followed by rigor, and temperature rose to 100°. Complained of severe burning pain in throat, and was very restless.

June 10th. $\frac{1}{2}$ iv injected into gland in front of ear, followed by rigor and temperature of 101.8°. Centre of affected cheek had become softer and more prominent, and on the following day the skin "broke," and pus was discharged.

June 12th. $\frac{1}{2}$ v injected into cheek. There was a slight rigor but no rise of temperature occurred. Complained that it "made him feel ill." The gland in front of the ear was found to be fluctuating.

June 13th. $\frac{1}{2}$ vij injected into cheek. Two hours afterwards had headache (which was an usual result), followed by muscular pains in limbs. Vomited twice.

June 20th. $\frac{1}{2}$ xij injected into cheek. No rigor had occurred since June 12th. The discharge from the cheek still continuing. Several other parts of the growth where injections had been given were softening, and some appeared less in size. Patient had lost 2 lbs. in weight since admission.

June 27th. $\frac{1}{2}$ xiv injected into gland at angle of jaw. Temperature rose to 101.5°.

June 28th. $\frac{1}{2}$ xv injected into gland in front of ear, followed by rigor and temperature of 103°. Patient had lost another $\frac{1}{2}$ lb. in weight. Feels weak and ill. Gland at angle of jaw rather larger, but softer. Gland in front of ear and secondary deposit on forehead both smaller and softer.

June 30th. Gland at angle of jaw breaking down rapidly.

July 1st. Portion of growth near right side of nose into which the last two injections had been given getting softer. $\frac{1}{2}$ xvij injected into gland at angle of jaw, followed by rigor and temperature of 103.2°.

July 2nd. $\frac{1}{2}$ xvij injected into gland at angle of jaw, followed by rigor and temperature of 103.8°. Although the parts into which the toxins have been injected appear to rapidly soften, the general infiltration of the growth is over a more extensive area.

July 5th. $\frac{1}{2}$ xvij injected into portion of cheek adjacent to the upper lip. Rigor and temperature of 101.4°.

July 6th. The soft area at the angle of the jaw almost "bursting."

July 7th. The portion of growth injected on 5th has now "broken down." Patient has lost another $\frac{1}{2}$ lb. in weight.

July 9th. The area injected on 5th has now "burst," and is discharging pus freely. The patient, who was much weaker and very depressed, decided to have no more injections.

The patient ultimately died at the end of September, 1895.

This case was doubtless an unfavourable one for injection with the toxins, but the rapid necrobiosis which occurred in the neighbourhood of the injections gave some hope for the future. Moreover, it is desirable that unsuccessful cases should be reported, so that we may form a proper estimate of

the value of this method of treatment. McBurney¹ has also recorded three unsuccessful cases.

It is, perhaps, interesting to speculate how the toxins act in these cases. Although tumours have been known to disappear in the course of infectious fevers other than erysipelas, I cannot think that temperature alone is the cause of the rapid destruction of the sarcomatous tissue, for in the case above recorded the temperature was at no time very high and never continued much more than twenty-four hours after injection. From the marked difference in action between the injections placed under the healthy skin and those into the growth itself it appears as if the toxins exerted some direct influence on the sarcomatous tissue, but whether of a specific or non-specific character it is difficult to determine.

Can it be that the lowly-vitalised cells of a malignant growth are more easily destroyed than the stable and resistant cells of normal tissue, by such baneful influences as toxins and febrile conditions acting in a non-specific manner? Whether this is so or not, I am unable to admit that there is necessarily any specific action of the toxins, or that the results support the theory of a bacterial origin of sarcoma and carcinoma upon which the streptococcus erysipelas has a directly antagonistic effect. Bruns seems unable to account satisfactorily for their action.

That all cases should be equally affected by the toxins is not to be expected. According to Coley, the osteo-sarcomata are least benefited, and from the fact that in the case reported above the effect was greater and more rapid when the injections took place into the growth itself, it seems that the more superficial forms of sarcoma would be more hopeful than those in which the growth has extended very deeply.

It is scarcely necessary to point out that this method of treatment should not be thought of except in cases that are unfit for operative interference. My chief object is to draw attention to a therapeutic measure which may have some good in it, and in such deplorably hopeless cases as inoperable malignant disease we may surely give it a fair trial; but in order that we may not arrive at false conclusions it is necessary that the diagnosis should in all cases be supported by microscopical examination.

A CASE OF CELLULITIS TREATED WITH MARMOREK'S ANTISTREPTOCOCCIC SERUM.

By FRANCIS HEATHERLEY, M.B., B.S., F.R.O.S.,

New Ferry.

On July 2nd I was asked to see J. P. B., aged 15 years, an engineering student, previously healthy except for an attack of acute rheumatism two years ago. He had a suppurating boil below the right angle of his mouth, which had been coming some days, and was making him feel ill. The temperature was 103° F. The boil was incised and some thick creamy pus let out. The patient felt faint. No enlarged glands were to be felt. During the next few days the swelling gradually spread over the right side of his face, becoming red and brawny, and being surrounded by an advancing zone of oedema; points of slough also appeared on the mucous membrane of the lower lip. The swelling was attended with very little pain, but the patient rapidly became weaker and was restless at night. The ordinary treatment of cellulitis, including incisions, was carried out, but apparently without benefit; the tissues, when incised, cut like potato, and bled slightly.

On July 6th nearly all his joints were painful and tender, but not enlarged nor red. He complained also of pain in the left side of his chest, and a pleuritic rub was heard in the axillary line. The surface of the brawny swelling was mottled in colour, and there was no fluctuation; the right half of his upper lip and the adjoining part of the cheek were 1 inch in thickness; there was tenderness over the region of the liver; there was no albuminuria.

For the above condensed notes of his progress I am indebted to my friend, Mr. E. W. Phillips, who had charge of him from July 2nd to July 8th. When I saw the patient again the swelling of the right side of the face made him almost unrecognisable. He was weaker, his sensibility blunted, and there was more restlessness than pain. He was in charge of a trained nurse, to whom great credit is due for the way he took his nourishment throughout his illness.

July 9th. No rub to be heard in the axilla, but there is a rub below the apex beat synchronous with the heart's action. This lasted two or three days, but was not followed by signs of effusion nor of pericarditis. He had a dry tongue, and was troubled with tenacious mucus accumulating in his mouth. He was at times slightly delirious. Some of the incisions, from which serum previously trickled, now exuded small quantities of thick pus on pressure.

On July 9th he was worse, and owing to his desperate condition, which was evidently tending to a fatal termination, I thought myself justified in trying the effects of Roger and Charrin's antitoxin. Having obtained his parents' sanction to the experiment, I telegraphed to London, but failed to hear of a supply. I accordingly tried Paris, and received two bottles from Dr. Marmorek on July 11th.

jaw extended backwards to the angle. On the right side the brawniness extended down to the clavicle. The ears were not affected. The patient was taking food well, but was weaker and apathetic. He did not flinch when his eye was syringed. The pulse was bad at times, and his back was beginning to look red. Fig. 1 is from a photograph taken on this date, for which and Fig. 2 I am indebted to my friend, Mr. Frank H. Elsby.

At 3 p.m. the serum arrived from the Pasteur Institute. At 4 p.m. a portion of skin over the right buttock was well scrubbed with soap and water, and washed afterwards with 1 in 20 carbolic lotion; 10 c.cm. of serum was injected deeply from a new syringe which had previously been soaked in 1 in 20 carbolic solution, then well washed out with boiled water, and the needle passed several times through the flame of a spirit lamp. The site of the puncture was covered with lint and strapping. The lad did not seem to feel the injection. In the evening two capillary tubes were charged with serum from the right temple and forwarded to Guy's Hospital for examination. The conjunctiva of the right eye gave way towards night, and serum began to trickle from it down the cheek.

On July 12th there was no increase or extension of the swelling. There was dysphagia, and he had coughed up

Fig. 1.

On that day the swelling extended over the forehead to the edge of the hairy scalp, to the middle line at the back of neck, beyond the clavicle in a downward direction, and slightly across the middle line of the front of neck. There was a pyramidal swelling upwards from the root of nose, in which the thrombosed frontal vein could be felt. The right eye was closed by brawny swelling of the lids, and was considerably protruded owing to the process having spread into the orbit. There was chemosis of the ocular conjunctiva. On separating the lids the patient said he could see quite well, and counted fingers held up before him. The nose was red and slightly swollen, and there was some oedema of the left eyelids. Both lips were much swollen, and the right halves brawny, making the use of a feeding-cup difficult. Brawny swelling of left cheek over region of lower

Fig. 2.

several lumps of bloody mucus. The pulse was running. In the afternoon the respirations were deep and laboured, and he appeared to be moribund. At 4 p.m. the rest of the serum, 13.5 c.cm., was injected. This lot of serum was slightly flocculent. In the evening he appeared rather brighter, although there was no other improvement apparent.

On July 13th the swelling of the right eye was less, and the eyeball less protuberant; the swelling of the nose and the left lids had gone; the lips were less swollen and the neck softer.

On July 14th the swelling in general was less, and the cheek was becoming less brawny. As his pulse and temperature remained up, it was decided to give him the benefit of a fresh supply of serum which had arrived from Paris. At 6 p.m. 21 c.cm. were injected into the right buttock. There were no signs of local trouble at the sites of previous injection.

tions. He flinched when the serum was injected, and whenever his eye was syringed. Fig. 2 represents his appearance on this day.

On July 15th the swelling of the face was less in the morning, and diminished visibly during the day. He was ordered calomel gr. iij. He slept fairly well during the night, and on July 16th was much brighter, although still very weak and with a running pulse. The swelling everywhere was less and much softer; the skin was becoming more natural in colour over the swelling. Owing to the reduction in the swelling the thrombosed frontal and submental veins were more prominent. He turned his head about in bed to see who was coming in, and showed some choice as to his food. He opened his right eye pretty freely. He complained of his limbs aching very much. Owing to the calomel not having acted, the dose was repeated in the morning, and that having no effect, he was given ol. ricini ʒij in the evening.

On July 17th he was much worse; the bowels acted six times during the night and early morning. He was very low and apathetic; the circulation was evidently failing, although he was still taking nourishment well.

At 3 A.M. on July 18th he became very collapsed, and, although he rallied for a time, he eventually sank at 6 A.M.

Throughout his illness he took on an average in twenty-four hours milk 3 pints, eggs 4, meat extract ʒij, brandy ʒiv, champagne ʒj.

Report on Specimen of Serum by Guy's Pathologist.—Microscopic examination of serum showed the presence of a staphylococcus (probably staphylococcus pyogenes albus) in large numbers, whilst a blood serum cultivation gave abundant colonies of the same organism at the end of twenty-four hours.

REMARKS.—My friend, Mr. R. W. Murray, of Liverpool, who was very interested in the boy, and saw him with me on several occasions, agrees with me in the following notes. In the first place, I think the case worth recording, being, so far as we know, the first instance of the remedy having been tried in this country. Secondly, up to the date of the first injection the disease was, in our opinion, proceeding to a fatal termination, and in the natural course of events one would have expected the swelling to have increased rather than diminished as the end approached. The way in which the process stopped spreading and then diminished was, in our opinion, more than a coincidence. Thirdly, we should like to draw attention to the temperature, which, on reference to chart, will be seen to have risen after the first and fallen after

the second and third injections. Probably, at the advanced stage of the disease which our patient had reached it would have been better to have given 20 c.cm. as a first injection. There were apparently no bad results, either local or general, attending the use of the serum. We consider that if it had not been for the regrettable over-stimulation of the bowels the boy would probably have pulled through. Our experience of the serum in this case will encourage us to have recourse to its use earlier in the course of any future case.

Lastly, I take this opportunity of expressing my indebtedness to the Pasteur Institute for so promptly supplying a foreigner and complete stranger gratuitously with the serum in this case, as they did last year in the case of the diphtheria antitoxin before a supply was established in London. It may be hoped that this remedy will prove in its own way as valuable in a class of cases where in the past our efforts have had to be confined practically to keeping up the strength of the patient until the disease wore itself out, or vice versa.

A CASE OF ERYSIPELAS NEONATORUM TREATED BY ANTISTREPTOCOCCIC SERUM.

By ERNEST A. T. STEELE, L.R.C.P., M.R.C.S.,
Plaistow.

THE male child of Mrs. B., aged 3 weeks, presented on October 4th, 1895, dusky redness spreading downwards from the umbilicus over the hypogastric and iliac regions, buttocks, and upper part of the thigh. The redness also involved the penis and scrotum, which were very much swollen. Above the pubes the skin was of a purplish red colour, and pitted deeply on pressure. The umbilicus was not yet healed. The child was very ill, and refused the breast. The temperature was 102° F., the pulse 150. I gave an injection of 6 c.cm. of Ruffer and Robertson's antistreptococcic serum between the shoulders.

On October 5th the temperature was 101.2° F. The child was taking the breast, and looked better. The redness had not extended, had lost its defined margin, and the skin was not so tense. The scrotum was more swollen. Another injection of 6 c.cm. was given.

On October 6th the redness was fading, patches of normal colour appearing in affected area. The temperature was 100° F., and the general condition of the child much better.

On October 8th the child was doing well, but a fresh patch of redness had appeared on the left thigh, and the scrotum was sloughing in one place. The temperature was normal. A further injection of 5 c.cm. serum was given.

October 13th. Since the last note all has gone well, and were it not for the slough on the scrotum the child would be quite well. The slough is about the size of half a crown, and separating nicely. It involved the whole thickness of the skin and subcutaneous fissures. The slough separated on October 19th, leaving a granulating surface with healing margins. The ulcer left by the separation of the slough had healed on October 26th, and the child is now quite well.

REMARKS.—In the practice of the Plaistow Maternity Charity I have seen a fair number of cases of erysipelas neonatorum, but I have never seen one recover when the disease was so far advanced as in this case. I am convinced that the child's recovery is due to the antistreptococcic serum. No other treatment of any kind was adopted.

A CASE OF MULTIPLE ENLARGEMENTS OF THE (LONG) BONES WITH SPONTANEOUS FRACTURES.

By GEORGE GUNN SINCLAIR, L.R.C.P. Edin.,
L.R.C.S. Edin.,
Esh, co. Durham.

I WISH to bring under notice the following case, not only on account of the rarity of the disease, but also on account of the curious history of accidents which preceded it. The case has been under my care for the past five years.

The patient, R. S., a man, aged 37, is the third son of a

family of nine; four of these are alive. His family history on both sides is exceptionally good. R. S. was born on March 18th, 1858. He was a strong healthy child; he began to attend school at the age of 7, and continued until he was 11. At that age he started work in a coal mine, and continued steadily at work until the age of 13. He was employed as a "putter," and later as a "hewer." For the next seven years he frequently complained of pains of a rheumatic character in his legs and arms, but these did not hinder him from working. When he was 27 years of age he met with an accident. He had a severe wrench of his right shoulder, necessitating his stopping work for nineteen weeks. After that time he returned to work, but complained of gradually increasing weakness in the shoulder. Five weeks after re-starting he received a second injury. He fell and dislocated the left hip-joint, which was reduced by a qualified practitioner. Owing to this accident he was confined to bed for eight weeks, subsequently being able to get about with crutches, and later with the aid of a stick. While in this condition he slipped and fell downstairs, fracturing his right humerus. This occurred in November, 1885.

From this time he has never been able to get about. He has been confined to bed, being occasionally lifted into an invalid chair, on one of which occasions the accompanying photographs were taken. During that time there has been a gradual increase of his symptoms. The right humerus increased in circumference to 14 inches, growth appearing on the lower third of the right radius and ulna, which measure 7½ inches in circumference. The digits of the right hand are deformed. There is a growth the size of a lemon on the left clavicle at its sternal end. The left humerus, radius, and ulna are normal. The left hand is deformed, there being also a large growth on the thumb. The trunk is well nourished and normal in size. There are no changes in the spine or in the pelvic bones. The condyles of the right femur are greatly enlarged but the bone is normal in its length. The right tibia is enlarged; the measurement round the calf is 13 inches. The left femur is enlarged throughout, measuring 17½ inches in circumference. The left tibia and fibula show irregular thickenings throughout their entire length. The

circumference below the knee is 15 inches; both feet are deformed. The muscles of the extremities are everywhere atrophied, particularly in the right arm. There have been spontaneous fractures of the right tibia below the knee, and of the left tibia and fibula in their middle thirds. The bones of the head are uniformly enlarged, the occipito-frontal measurement being 24½ inches, the occipito-mental 23 inches.

During his illness he has passed large quantities of phosphates in his urine. He suffers occasionally great pain from the passage of phosphatic calculi, one, the size of a bean, being extracted by instrumental aid. He has contracted stricture from laceration of the urethra during the passage of the calculi. His other systems are normal. During this year his condition has somewhat improved, and from being totally incapacitated from all exertion he is now able to busy himself in light fancy work, for which he has shown great aptitude.

CASE OF DIPHTHERIAL CONJUNCTIVITIS IMPLICATING BOTH CORNEÆ TREATED BY ANTITOXIN.

BY

W. M. HAMILTON, M.D., and A. EMRYS-JONES, M.D.,
Patricroft, Lancashire. Surgeon, Manchester Royal Eye Hospital.

On February 28th I found M. M., aged 1 year, suffering from a mild attack of scarlatina, with temperature 103°, rash well marked, and no throat symptoms. The rash disappeared, temperature fell, and desquamation began on March 4th. On March 16th the upper lid of the right eye became swollen, the skin smooth and shining. The margins of the eyelids were red, and there was photophobia. Next day the conjunctiva was very vascular and dotted with red spots. The left eye similarly affected. Ordered a sedative astringent lotion. Next day the lids could be everted only with the greatest difficulty; the conjunctiva was yellow, smooth, and infiltrated with a thick fibrinous exudation. I ordered *loto hydrargyri perchloridi* 1 in 5,000 every hour. Next day the cornea manifested an exudative opacity, and a marginal ulcer appeared on the right cornea, extending to one-sixth of its circumference. The bottom of this ulcer was covered with a yellow opacity. Dr. A. Emrys-Jones now saw the case with me. He diagnosed diphtherial conjunctivitis. He advised the application of nitrate of silver, gr. xx. 5j every three hours, and that the eyes should be syringed with solution of boroglyceride. On March 21st there was evidence of the throat being affected, a large diphtheritic patch appearing on the tonsil. That evening, by the advice of Dr. Emrys-Jones, I injected 10 c.cm. diphtheria antitoxin. By next morning the temperature had fallen from 102° to 99.2°, the swelling of the lids was less and a piece of membrane was detached from the lids. I again injected the antitoxin, and again with marked improvement. The membrane disappeared from the throat and from the lids. We still continued the application of nitrate of silver and boroglyceride. On March 26th, as

there was a recurrence of the membrane in the throat, I again injected the antitoxin. From this time there was no relapse, and the cornea began to clear. The condition of both eyes at this time was inability to open the lids, great vascularity and redness of the conjunctiva, purulent discharge, and complete opacity of the cornea. We continued the nitrate and boroglyceride, and instilled atropine every two hours, substituting eserine at night and in the morning. The layers of the cornea separated and came away in the syringing. Unfortunately the infiltration of the right cornea was so deep that perforation took place. The left eye has cleared up entirely with the exception of a very small nebula at the lower margin, which is rapidly disappearing. The sight in this eye is perfect; the child can pick up crumbs from the floor, and can see the normal distance. The right cornea is also clearing, and we are hopeful that in time we may by an iridectomy restore full vision to the eye.

We report this case on account of the extreme rarity of preservation of sight in this fortunately rare and dreadful disease.

**A CASE OF CUT THROAT, IN WHICH ALL THE
CAROTID ARTERIES AND ALL THE JUGULAR
VEINS ON ONE SIDE WERE LIGATED:
PERFUSION OF SALINE SOLUTION:
RECOVERY.**

By W. THELWALL THOMAS, F.R.C.S.,

Assistant Surgeon to the Royal Infirmary, Liverpool; Demonstrator of
Surgery and Surgical Pathology, University College, Liverpool.

J. E.,¹ aged 45, was brought on a police ambulance to the infirmary on October 5th, 1894, having attempted suicide half an hour before. We were conducting the out-patient clinic at the time, so there was no more delay. He was unconscious,

modically dropping, with feeble inspiratory attempts. There was a deep wound in the left side of the neck (produced by a penknife). The sterno-mastoid and omo-hyoid muscles were divided, the internal jugular vein was cut through, its cut ends were collapsed and three-quarters of an inch apart, the common carotid artery was cut into, but not divided. The

Fig. 2.

Fig. 3.

Fig. 1.

deathly white in colour, and pulseless; the lower jaw spas-

¹ The patient was shown at the Liverpool Medical Institution, Dec., 1894.

thyroid cartilage was notched, and the external and anterior jugular veins severed. The perfusion apparatus and saline solution was sent for. Clamp forceps were immediately applied to the cut vessels, and one on each side of the aperture in the common carotid, from which a small spurt of blood, certainly not half a teaspoonful, was jerked out.

The left median basilic vein was exposed by an incision, to which the patient did not object, being "too far gone," and 20 ounces of warm saline solution slowly perfused. An ordinary glass syringe with a capacity of 5 ounces was used, with india-rubber tubing attached to a cannula in the vein. The effect was most marked. After 7 ounces he took a short, distinct inspiration, at 10 ounces a deeper one, and his radial pulse was now felt beating feebly. After 15 ounces his breathing became regular and deep; at 18 ounces he opened his eyes, but did not appear to be conscious. The clamped vessels were now tied with catgut, the wound cleansed with carbolic acid lotion, and dressed with cyanide gauze.

Thus far the treatment had been carried out on the ambulance, elevated at the foot. He was now wheeled to bed, surrounded by hot water bottles, and the foot of the bed elevated 18 inches. The house-surgeon, Mr. McCormack, accompanied him, and remained by his side until we saw him an hour later, when he had sufficiently recovered to answer to his name, when called loudly, although he did so in a very squeaky voice. He rapidly improved in condition until October 27th (the twenty-second day), when a violent hemorrhage occurred, preceded a few hours previously by a small trickle, easily controlled by pressure.

The house-surgeon, assisted by his colleagues, at once opened up the wound, found blood oozing from the distal ends of the carotid and jugular, which were promptly clamped. My colleague, Mr. R. A. Bickersteth, who was in the infirmary, arrived in time to apply ligatures to the common carotid, which was not sound; this necessitated search for the internal and external carotid arteries, which were tied, and the internal jugular with a small branch entering it. The patient was very collapsed after this, but quickly rallied, only to suffer from another hemorrhage nine days later (November 5th) from the internal carotid artery. The house-surgeon, Mr. T. H. Agnew, applied sponge pressure until our arrival, when on removing it no bleeding occurred, so we decided this time to rely on pressure, a sponge well sprinkled with iodoform under cyanide gauze, and a figure-of-8 bandage of elastic webbing around the forehead and neck. A quart of hot water was injected into the rectum, all of which was absorbed, and acted most beneficially in reviving him. This dressing was removed in two days, and cyanide gauze only used.

From this time he made a slow recovery and was discharged, but returned with a small sinus in the lower part of the neck, in which we found a catgut ligature; it was removed, and the wound quickly healed.

The result of all this interference in detail is found to be: weakness of the sterno-mastoid, paralysis of the trapezius owing to division of the spinal accessory in the posterior triangle of the neck; paralysis of the deltoid, due to injury of the brachial plexus; paralysis of the left vocal cord, due to division of the left pneumogastric; paralysis of the left hypoglossal nerve and a few filaments of the facial; division of the left sympathetic, evidenced by contracted fixed pupil and diminution of palpebral fissure; and, finally, when he coughs, a distinct hernia of the left lung into the root of the neck. Put thus in detail the list looks formidable, but the only symptom that causes any inconvenience to the man is the weakness of the shoulder, which necessitates him doing light labour, of course, at less remuneration than his former employment. We do not feel justified in endeavouring to reunite any of the severed nerves in such a cicatrised neck.

We cannot too highly praise the assistance rendered by Mr. McCormack and Mr. Agnew, house-surgeons, on whom, of course with their colleagues, the success of the case really depends for their prompt treatment of the secondary hemorrhages, which might easily have proved fatal in less capable hands. The case is interesting as an example of what some patients can recover from. It teems with many important physiological points, and, as far as we can gather, the man has not altered mentally in the slightest.

The photographs were taken in May, 1895.

Summary of Treatment.—October 5th. Ligature of common carotid in two places, 5 and 6 (Fig. 1). Ligature of internal jugular in two places, 1 and 2 (Fig. 1). Ligature of external and anterior jugular. Perfusion of 20 oz. saline fluid. October 27th. Secondary hemorrhage; attempted ligature of common carotid, 3 (Fig. 1). Ligature of external carotid, 4 (Fig. 1). Ligature of internal carotid, 5 (Fig. 1). Ligature of internal jugular and branch, 6 and 7 (Fig. 1), by Mr. R. A. Bickersteth. November 5th. Hemorrhage from internal carotid treated by packing and pressure. Injection of 2 pints of warm water in the rectum.

THORACOPAGOUS MALE TWINS WITH A COMMON HEART: TRANSPOSITION OF VISCERA IN ONE TWIN.

By C. M. KEMPE, M.R.C.S., L.S.A.,
New Shoreham.

On May 2nd I attended Mrs. A. during her first confinement. On my arrival at 2.30 p.m. the nurse informed me that the pains came on at 4 a.m. on April 30th, but were not sufficiently bad for her to be sent for until 8.30 a.m. on May 2nd. The pains at that time came at intervals of about every ten minutes, and the membranes had ruptured between 10.30 and 11 a.m. The pains becoming more frequent and stronger I was sent for at 2 p.m.

I found the os uteri well but not fully dilated, and the head presenting. The pains were strong and forcible, coming on every three or four minutes.

In a short time the os became fully dilated, the head coming down at each pain, but receding in the interval in such a manner that I came to the conclusion there was some obstruction from above which prevented it descending, as the pelvis was capacious and the pains very strong and expulsive. Shortly after 4 p.m. I applied the long forceps, and with great difficulty delivered the head, and then, with much trouble, got down the arms and shoulders. Directly the second arm was delivered a third arm shot down; then I

found I had to do with connected or interlocked twins. Finding it impossible to deliver the woman unaided I procured the assistance of my partner, Dr. Fuller. On his arrival he took the arms and shoulders, already outside, of the first infant, which presented and bore it well back, giving it a twist so as to bring the body in the oblique axis of the pelvis. I at the same time pulled on the other arms that protruded. By these means the first infant was soon delivered, the buttocks coming out under the arch of the pubes, sheeling out as it were. The second child quickly followed, the breech coming first. By my traction on the protruding arm it probably lessened the tension of the band between the two infants, and so allowed us to hook out the first. The placenta (there was one placenta and only one umbilical cord) followed

almost directly, and the uterus contracted. The woman has made a good recovery without a single bad symptom, and is now about her usual duties. I may mention that she went to her full time.

By a post-mortem examination it was found that the infants had not breathed; their weight was about 13 lbs., length 18½ inches, circumference of heads respectively 14 and 13½ inches. There was only one heart, which was lying in the space between the two, and had six cavities—namely, four auricles and two ventricles.

Playfair mentions only nineteen such cases as having been recorded.¹

NECROPSY OF TWINS JOINED TOGETHER, BORN MAY 2ND, 1893.

The specimen apparently represents twin pregnancy at term. The twins, both male, and well-nourished, are united face to face by the anterior part of the thoracic and abdominal walls from the top of the sternum to the insertion of the umbilical cord. Below the umbilical level the anterior abdominal walls are wanting in both children, the abdominal viscera being seen through the peritoneal membrane. The children are twisted so as to make both faces look to the front, and both gluteal regions backwards and outwards.

Measurements.—Circumference, occipito-frontal, of right head ... 13½ inches.
Circumference, occipito-frontal, of left head ... 14 inches.
Circumference round the united thorax ... 17 inches.
Length of specimen ... 18½ inches.
Weight of specimen ... 12 lbs. 8 ozs.

For the purpose of inspecting the viscera with as little disturbance as possible incisions were carried: (1) Down the line of union in front as far as the umbilicus; (2) outwards from the upper end of the first incision along the two anterior clavicles. The flaps thus formed were turned back, exposing the anterior sternum and ribs.

Each sternum is composed of half a sternum belonging to each foetus, and between the two sternums thus formed is a space. Diagrammatically it might be represented somewhat thus: Suppose A and B represent two transverse sections of

sternums and ribs placed facing each other. Let the interrupted line represent a division of each sternum; then let the upper and lower part (in the diagram) of each sternum unite with the opposite side, and you have the condition present. The anterior ribs were divided, and the breastbone turned up.

Thorax.—The heart, for there was only one, was found lying in the space (c). It was large, and had six chambers, four auricles, and two ventricles. It would appear that each child had had the rudiments of a perfect ventricular cavity, but though the septum separating them was well marked, yet there was no trace of the intraventricular septum which should have divided each ventricular space into right and left chambers. The aortæ and pulmonary arteries sprung directly from their own ventricular cavities. The aorta of the left child curved over to the right, and ran down the right side of the spine. The viscera in this child were, of course, transposed. There was a common pericardial sac, but four pleural sacs. There were four lungs, in which it was evident that no attempt at respiration had taken place.

Abdomen.—There was one common peritoneal cavity. The livers were complete, and united in the middle line. There were two gall bladders and a double set of all the other abdominal organs, those of the left child being transposed, situs

mutatus being the rule in one of a pair of thoracopagus twins.

MEMORANDA: MEDICAL, SURGICAL, OBSTETRICAL, THERAPEUTICAL, PATHOLOGICAL, Etc.

FOREIGN BODY IN ORBIT: THE BILL OF A FISH.

LANCE-CORPORAL G. S., 2nd Battalion West Riding Regiment, while at a bathing parade in Bantuloe, W.I., on July 21st, 1891, was struck by a fish. About half an hour later, on admission into hospital, he presented a small lacerated wound beneath the right orbital ridge, at the junction of its outer and middle thirds. On examination with the finger a rough body was felt embedded in the orbit. This required some amount of force for its removal, having apparently passed from the outer side downwards and inwards behind the eyeball, to be wedged into the bones on the inner side of the orbit. Some slight bleeding occurred from the right nostril on its removal. This foreign body was found to be the bill of a fish, 2½ inches in length: the greatest

Natural size.

width was ½ inch, and it was armed with six teeth, the longest of which was ½ of an inch. The eyeball, which was intact, had been levered forward; it protruded considerably and was fixed and immovable. The conjunctiva on the edge of the globe was torn transversely. There was some ptosis. The pupil was widely dilated and reacted slowly. There was no vision except perception of light. The man was subsequently invalidated from the service with loss of vision from atrophy of the right optic disc. Surgeon-Major Whitehead, A.M.S., Assistant Professor of Surgery, Netley, reports that on his admission into Netley on April 18th, 1892, there was found to be "marked atrophy of the right optic disc."

W. BURRELL THOMSON.

York.

Surgeon-Major, A.M.S.

VIPER BITE: A PERSONAL EXPERIENCE.

On July 12th, the weather being warm, while incautiously handling a viper 16 inches in length, the reptile struck me with its fangs, inflicting two small punctured wounds on the left forefinger close to the metacarpophalangeal joint. I was in good health, and weighed 136 lbs. at the time of the injury. Grasping the wrist I sucked the wounds energetically, spitting out the blood withdrawn, and about ten minutes later applied strong solution of ammonia to the punctures, nothing while I did so that my conjunctivæ were much injected, and feeling slight throbbing at the temples. The finger and hand had commenced to swell immediately after the injury was inflicted.

The heart's action now became rapid, and numbness of the lips and tongue, with swelling of them and the sublingual glands, followed. Within half an hour of the accident epigastric sinking and vomiting occurred, the vomit having a peculiar earthy taste; colic, purging and stranguary succeeded, while the swelling of the lips, tongue, and sublingual glands increased, until deglutition and articulation were abolished.

These symptoms continued to intensify, with much prostration, an intermittent pulse (140), and slight cyanosis, till about three hours after the inoculation, when improvement commenced. The general symptoms of poisoning and the swelling about the mouth then quickly disappeared, conversation and swallowing being easily accomplished two hours

¹ See No. 76, Royal College of Surgeons Museum, Teratological Series. The heart (No. 76) is common, and has two ventricles and an auricle. There is no situs mutatus in either twin.—(Ed.)

later. At no time were the mental faculties in any way impaired. Meanwhile lymphangitis and swelling were rapidly extending over the hand and up the forearm, and increased for forty-eight hours, spreading along the anterior and posterior axillary folds to the side of the thorax, the whole upper extremity becoming greatly swollen. Much cedema occurred, especially about the elbow. Pain was not so severe as the appearances suggested, and the temperature at no time reached 100° F. These local effects gradually subsided, no vesication, suppuration, or sloughing taking place, and at the end of a week a sling was not required. From the fifth to the eighth day an urticarial eruption with much itching frequently recurred round the punctures and on the back of the hand; slight puffiness about the knuckles and brassy desquamation of the forearm continued till the end of the third week, though I felt no inconvenience from the injury after the tenth day from its infliction.

As treatment, whisky and sal volatile were taken while swallowing was possible, and the tension of the arm was much relieved by hot water sponging. The most serious symptom was the swelling of the lips, tongue, and floor of the mouth, seemingly due to contact with the venom; fortunately this did not extend so as to embarrass respiration. The mucous membranes appeared to be intact, so that the propriety of ever sucking a snake wound may be questioned. The strangury was not accompanied by any change in the urine. It will be noticed that injection of the conjunctivæ was the first phenomenon of general poisoning observed.

Trybridge.

W. H. Bowze, F.R.C.S. Eng.

TREATMENT OF DIPHTHERIA BY LOCAL APPLICATION OF GERMICIDES.

In the *BRITISH MEDICAL JOURNAL* of September 21st I expressed the belief that the fatal accumulation of the diphtheria toxins is prevented by local application of germicides, when the disease is recognised early. The following case (one out of many) is a striking instance in favour of that statement:

On Sunday evening, September 20th, E. W., aged 22, came under my notice suffering from sore throat. Her case was clinically diagnosed to be diphtheria, and the correctness of this was upheld by bacteriological examination in the laboratory of the Clinical Research Association, which revealed the presence of diphtheria bacilli and staphylococci. When first seen both tonsils were thickly coated with exudation. A tube of blood serum having been inoculated with some of this exudation, the parts affected were carefully and freely infiltrated with pure magnesium sulphate. This treatment was continued throughout Monday, September 20th, and Tuesday, October 1st, and on Wednesday morning (a period of sixty hours from the time the case was first seen) the throat was perfectly clear. She was kept under observation until Saturday, October 14th, but there was no return of the disease, nor any symptoms of secondary toxæmia.

It is possible that other germicides might have acted equally well, but having used this drug for more than seven years with perfect success, I have no desire to experiment with any other.

Barnes Court Park, W.

EDWARD R. MARTIN.

A CASE IN WHICH A CONVULSION OCCURRED IN A HEALTHY WOMAN DURING THE ADMINISTRATION OF CHLOROFORM.

We so frequently see cases of death during the administration of an anæsthetic, that it is well to place on record all cases where any events of an unusual character occur, whether followed by death or not, since it is only by the accumulation of such cases that we can arrive at the truth as to the relative danger or safety of the various anæsthetics. In this case the chloroform used was manufactured by Messrs. Duncan and Hoadley, and came from the same bottle has been used by me both before and since without any unusual results.

Mrs. M., aged about 34, a primipara, went into labour about 2 a.m. on October 13th. The presentation was vertex, position *L.O.P.*; the cervix was very rigid, and dilatation of the os in consequence slow, in spite of the administration at various times of opium and chloral hydrate. There was a great deal of vomiting. At about 2 P.M. on October 14th

the os was almost fully dilated, but after the membranes had been ruptured the pains became feeble, so that little progress was made. Between 3 and 4 p.m. I commenced to administer chloroform, with the intention of applying forceps. She took the anæsthetic very quietly, and all went well for the first few minutes, when suddenly clonic spasms of the face and limbs came on, the pupils being widely dilated and not reacting to light. The clonic spasms passed into tonic, and as the chloroform was pushed further these in their turn passed off. As soon as she was deeply narcotised the forceps were applied to the head, and delivery of a large healthy child effected in about ten or fifteen minutes. There were no further convulsions. The puerperium was normal, and she made a good recovery.

A few hours after delivery the urine was drawn off with a catheter and was found not to contain any trace of albumen, its specific gravity being 1025. I found on inquiry that she had always been quite healthy, and that she had never before had any convulsion nor suffered from any nervous disorder; she was not at all nervous or excited during the prolonged first stage of labour, and showed no symptoms of hysteria. Her heart was found to be quite healthy and normal except for the slight hypertrophy of the left ventricle usually found in the later stages of pregnancy.

In the *BRITISH MEDICAL JOURNAL* of October 19th is an account of a death under chloroform where a clonic spasm preceded death, and this frequently appears to be the case. Here, however, a convulsion occurred in a perfectly healthy woman, apparently as the result of the administration of the chloroform, and yet no untoward result followed.

LONDON HOSPITAL.

THE TREATMENT OF SEVERE BURNS.

(Under the care of Mr. HURRY FENWICK.)

[Reported by HAROLD L. BARNARD, M.B., F.R.C.S.,
House-Surgeon.]

The mortality in burns divides itself into two periods—early and late. Early mortality is due to shock, and this depends upon two causes—pain and cold. Late mortality is due to suppuration, but is, in most cases, immediately caused by infection.

To strip and dress a child directly after the accident is an unnecessary exposure to cold, and adds more pain to that already experienced. Personally I have found it less painful to be burnt than to be dressed after being burnt. These two causes combine gravely to increase the shock and often accelerate a fatal issue.

Our treatment is as follows: The child is wrapped in a blanket just as it is, and the blanket secured with safety-pins around the neck and chest, so that its movements may not unloose it. Hot-water tins are placed in bed with it, and the bed moved before the fire, with a screen behind it to protect from draughts and to reflect the heat upon it. When shock from cold is avoided and the heat of the body somewhat restored.

To relieve the shock from pain brandy and opium are given at once and the child is not dressed until well under the influence of the latter. The dose of opium should be not less than four or five minims of the tincture for a child of 3 or 4 years old, and about two drachms of brandy should be given with it. In most cases, if left alone, the child sleeps for less than an hour and does not awake for three or four hours, when it is warm and draws from the opium. Not only have we had no ill-effect from the above dose of opium, but we give a further dose of three minims should the child still be crying at the end of an hour.

When the child awakes the screen is drawn down, and one

It is a saying with us that "Justice does not sleep for long night days."

part after another rapidly exposed and dressed with zinc ointment and cotton wool, and the blanket once more wrapped round it. It is quite unusual for the child to cry whilst this is done. These dressings are left undisturbed until the fourth day, when suppuration commences—another great saving of pain.*

The three or four days which follow are spent in preparation for the drain of suppuration. Tincture of opium is given in doses of π ij or π ij every fourth hour to induce sleep and to prevent restlessness and friction. The rule of never awaking the child for its medicine is sufficient safeguard against overdose. Thirty minims of brandy are given every hour to such a child, and from the morning following the accident it is induced to take as much food as circumstances will allow, in spite of the temperature of reaction, which will fall of itself on the third or fourth day.

When suppuration has set in, we put our trust in daily dressings and plentiful food with brandy. If there be much pain or restlessness opium is still continued, otherwise it is stopped. The great fear at this stage is diarrhoea, and this we vigorously combat at its very inception with carbonate of bismuth gr. x, ipecacuanha wine π ij, tincture of opium π ij, mucilage and dill water \mathfrak{z} ij every fourth hour; for this reason also, we never give aperients for constipation, but enemata as in measles.

It would be interesting to learn something definite of the relations of burns to scarlet fever. A quite disproportionate number of burns (2 out of 8) develop on about the fourth day signs and symptoms of scarlet fever—rash, throat, tongue, and temperature. There have been very varying opinions as to this. Some deny that it is scarlatina, and these attribute it to boracic acid absorbed from so large a surface, but the symptoms have all appeared in a case dressed entirely with zinc ointment. The explanations of those who think it scarlet fever are ingenious. Some say that children sickening for this disorder have a natural tendency to drop things and to stumble in the fire; whilst others attribute it to the ready infection of a large raw surface.

ROYAL INFIRMARY, EDINBURGH.

A CASE OF BACKWARD DISLOCATION OF THE CARPUS.

(By JAMES HOSSACK, L.R.C.P. & S. Edin., House-Surgeon to the Infirmary.)

This condition is so rarely met with that I think the following case may be of interest:

J. B., aged 16, came to the hospital on September 10th, 1895. He gave the following history: Twenty minutes previously he was riding on a lorry, and, in attempting to jump off when it was in motion, caught his foot against the edge

and fell to the ground, landing on the flat of his hands. At first sight, to all appearances it was a case of Colles's fracture, and, seen from the radial side, was a beautiful specimen of the "silver fork" deformity seen in that fracture. The

* Here might be mentioned another saying current in our children's ward, "If a burn or scald soon after admission it will die."

photograph shows the condition fairly well. On examination, however, the styloid processes of both the radius and ulna were in their usual positions, while the prominence on the back of the wrist was not limited to the radial side of the forearm, but was equally marked over the ulnar. On the palmar aspect the ends of both radius and ulna made an abrupt prominence, while the flexion lines there were especially well marked.

Reduction was simple. The forearm was steadied and slight extension made on the hand. Suddenly the carpus slipped back with a distinct "click." There was no fracture present; this was definitely ascertained after reduction. No crepitus could be felt when rotating the radius. The whole bone rotated in one piece, and no prominence or deformity was to be made out along the course of either bones. There was no suspicion of return of the condition. It was put up in anterior and posterior splints, and resort was early had to passive movement. The wrist is now—three weeks after—perfectly well; the boy, however, complains of weakness and stiffness in it. The exact position of the hands, an important point, unfortunately could not be accurately got. The palms of both hands were slightly bruised and covered with dust, indicating, I think, that the boy's version is correct.

My thanks are due to Mr. Hodsdon, surgeon to the infirmary, for permission to publish the case.

NORTHUMBERLAND COUNTY ASYLUM, MORPETH.

TRAUMATIC ANEURYSM OF THE ANTERIOR TEMPORAL ARTERY.

(By BURTON ROBINSON, M.B., M.R.C.S., Assistant Medical Officer.)

W. W., aged 70 years, suffering from organic brain disease, has had rare but severe epileptic attacks during the last two years. On September 4th he had one of his seizures, and fell

forward off a garden seat. The injuries received consisted of slight cuticular abrasion and severe contusion of the tissues about the left external angular process of the frontal bone. In a few days the diffused ecchymosed swelling subsided quietly, with the exception of a circumscribed tumour of the size of half a bantam's egg just above and behind the left

external angular process of the frontal bone. It fluctuated, but did not pulsate, and was regarded as a hematoma. Local redness and increase of heat gave indications of an inflammatory state of the tissue about the tumour, and, with fluctuation, strongly suggested the supervention of suppuration and abscess. The margin of the tumour underwent distinct induration, whilst the more central parts gave physical signs of fluid contents. Five weeks after the fall slight enlargement of, and pulsation in, the tumour were discovered. Pulsation was expansile; a systolic *bruit* was audible with the stethoscope; constant pressure over the tumour produced diminution in size and tension; pulsation ceased on application of digital pressure to the superficial temporal artery at the root of the zygoma, and more locally on pressure over the anterior temporal artery at the margin of the swelling. The partially emptied tumour refilled, with distinctly perceptible and palpable pulsations on relaxation of the pressure on the feeding artery.

The illustration shows the condition at this time. The increase in size slowly continued, stretching the skin. Shortly after the aneurysmal nature of the tumour was recognised the patient was anaesthetised with chloroform, the sac laid open, the peripheral laminated fibrin and central dark jelly-like coagulated and fluid, blood turned out, and the spouting artery ligatured. The cavity was drained for 48 hours, and the wound closed without further trouble. It is possible that the direct result of the fall was a simple hematoma and contusion of the anterior temporary artery, leading subsequently to arteritis and weakening of the vessel wall, and final rupture, thus explaining the onset of pulsation after a definite interval of five weeks.

Small circumscribed traumatic aneurysms usually occur in connection with injury to such arteries as the palmar, plantar, radial, and ulnar. Erichsen mentions having seen two cases of traumatic aneurysm of the temporal artery resulting from cupping in the temporal region. The nature of the exciting cause, and the uncommon seat of the aneurysm, with the close likeness of the tumour to a suppurating hematoma in the early period, make the case noteworthy.

REPORTS OF SOCIETIES.

PATHOLOGICAL SOCIETY OF LONDON.

HENRY TRENTHAM BUTLIN, D.C.L., F.R.C.S., President, in the Chair.

Tuesday, December 3rd, 1895.

A NEW FORM OF STERILISER AND INCUBATOR.

MR. P. D. ADAMS exhibited an apparatus devised to serve both as a steriliser and an incubator. This consisted of a large glass cylinder secured to a metal stand, and provided with an india-rubber cork, perforated for a thermo-regulator, etc. Steam could be admitted so as to sterilise media, etc., or the apparatus could be used as an incubator by allowing hot water to circulate around it. He called attention, also, to a method of making cultures on gelatine or agar films on cover glasses. The cover glasses are held between the coils of a spiral spring, which is weighted with lead so as to remain upright. A series of such covers could be prepared, and they could be left incubating after inoculation in the damp atmosphere of the glass cylinder. The air could be replaced by hydrogen where necessary.

MR. S. G. SHATTOCK did not gather what advantages such preparations possessed over those made by means of the ordinary moist chambers which could be placed in an incubator, and subsequently made permanent by removing the cover glasses, and drying and staining.

DR. N. PITT observed that, as the author claimed, the chief point in the apparatus lay in its being both a steriliser and an incubator.

In answer to Dr. GOODALL, MR. ADAMS did not think that the exposure entailed in removing the rubber cork to introduce the cover glasses was a serious occasion of contamination.

ADENOMA OF SEBACEOUS GLANDS.

DR. H. D. ROLLESTON described a specimen of what he considered as coming under the above term. The tumour

was removed from the outer angle of the orbit in a man, aged 67, and had been noticed many years. It consisted of a framework of fibrous tissue, was lobulated, and constructed of epithelial cells arranged in an acinous manner. Some of the cells were like those of sebaceous glands, others like those of rodent ulcer. A certain number of false pearls were present, but there was no calcification. As against the view that the growth was a rodent ulcer, he noticed the fact that it did not invade the dermis.

DR. A. A. KANTHACK regarded the specimen as one of rodent ulcer by reason of the atypical character of the cells. The rodent "ulcer" lay at first beneath the epidermis, and was a solid growth. Seeing that the tumour had been noticed so many years, he thought it arose probably as a sebaceous adenoma, and that this subsequently altered its characters.

MR. J. H. TARGETT recounted the case of a man, aged 45, from whom a sebaceous adenoma was removed from the region of the zygoma, superficial to the parotid. A sebaceous cyst had previously been removed from the same situation. The cells were arranged in alveoli, and he regarded the new formation as either a sebaceous or sudoriparous adenoma.

MR. A. A. BOWLBY agreed with Mr. Targett that rodent ulcer was an unfortunate term, since the disease arose in the substance of the skin and did not necessarily ulcerate. The possible origin of such in sebaceous adenomata was a subject that was well worth investigation. In elderly people it was not rare to see small multiseptate rounded swellings on the face which might remain quiescent for years, and in such possibly rodent ulcer often started.

THE PRESIDENT had seen a case of the kind referred to by Mr. Bowlby, where he had excised a rodent ulcer which started in such a swelling, though the nature of the others was not determined. Such formations could not be considered malignant, or rodent, unless they infiltrated surrounding structures; this was the test of their real nature.

DILATATION OF THE (ESOPHAGUS.

DR. H. D. ROLLESTON recorded this condition in a boy, aged 8 years, who died after six weeks' vomiting, which followed whooping-cough. After death the dilated oesophagus contained a certain amount of food; the muscular coat was hypertrophied. There was nothing else abnormal in the body. He did not think the case bore out Sir Morell Mackenzie's view that this condition arose from general weakness of the tube, seeing the muscularis was hypertrophied. As there was no organic stricture at the cardia, one had to assume a functional one. He considered a permanent spasm of circular fibres disproved, because there was no annular hypertrophy, and he thought that the closure of the cardia was due to inhibition of the longitudinal fibres, the contraction of which was the normal means of dilating this orifice. It was noteworthy, as pointing to a nervous origin, that a brother of the boy had died of vomiting after scarlet fever, and an uncle was also said to have died from vomiting. The whooping cough was the exciting cause, such a neurotic predisposition existing. In answer to Dr. Goodall, he did not do more than connect the cough in this way with the dilatation.

GALL STONE IMPACTED IN THE SMALL INTESTINE.

MR. J. HUTCHINSON, jun., showed a calculus 9.5 cm. in circumference, and 121 grains in weight, which was removed during life through a longitudinal incision of the small intestine. The symptoms, in a woman, aged 60, were quite obvious, and comprised jaundice and hepatic colic. Acute intestinal obstruction was present for four days before operation, the gallstone having passed by ulceration into the duodenum. It was tightly grasped by the bowel, and lay at some distance from the ileo-caecal valve, the intestine below it being empty and contracted. The patient rallied, but subsequently died from causes not very clear. He remarked that the calculus was comparatively small, though it caused fatal obstruction. It was of the size of a Murphy's button, which might also cause complete obstruction when set free into the lumen of the small intestine. A calculus of an inch diameter was probably as much as would traverse the small intestine. He had collected about thirty cases of fatal obstruction arising from the impaction of biliary calculi. The author referred to specimens showing fatal obstruction due to a damson stone, and even to a cherry stone.

Dr. SEPTIMUS GIBSON recalled one case of the kind—fatal after nine days. Kneading of the abdomen was had recourse to, the modern procedures of surgery not having then arisen.

THE FORMATION OF INTRA-ABDOMINAL BANDS.

Mr. J. HUTCHINSON, jun., exhibited a remarkable instance of band, about six inches in length, which arose from the broad ligament, and was attached at the other end to the great omentum. The latter end was dilated into a small cyst, and the structure was evidently a greatly elongated hydatid of Morgagni. The elongation had been effected by the excursions of the great omentum, which were known to occur during life. He had seen the great omentum folded up after death so as to conceal the liver. Dr. Perry had recorded instances of bands arising in elongated appendiceal epiploides. He thought that many cases of volvulus really depended upon the presence of slender cord-like bands. That bands were not always due to peritonitis was shown by the absence of any history of this, as well as by the absence of adhesions, etc., after death. It had been suggested by an American writer that persistence of the omphalo-mesenteric vessels was a cause of band, the vessels remaining connected with a umbilicus or forming an attachment to the mesentery, etc., after becoming free at the end. Such a persistence of vessels would be parallel with that of the hydatid artery. As an instance of band he cited the case of Mr. Maccully's, where a ring of fibrous tissue, apparently torn from the neck of a hernial sac, was found round the gut after a resection of the same.

Mr. A. A. BOWLEY noticed that the two commonest forms of band were Meckel's diverticulum and the vermiform appendix; but sufficient attention had not been paid to those arising from adhesions between the intestine and the caecum or mesenteric glands. In the last set of cases there was no history of acute peritonitis, and no widely distributed lesions were necessarily found after death. In other cases of tuberculous peritonitis there might be definite bands.

Dr. N. PITT agreed as to the importance of tuberculosis in the production of bands. He had seen such. The occasionally great length of the adhesions was noteworthy. He had seen the omentum rolled up into three long cords. Possibly a local injury leading to inflammation was the originating cause of certain such bands as were sigle, especially as their seat was sometimes the sacral region. In such circumstances there would be no history of any general acute peritonitis.

Dr. SEPTIMUS GIBSON did not think peritonitis explained the existence of bands, for they were not common in children in whom tubercle of the glands and peritoneum were most frequently met with.

Mr. J. H. TARRANT cited the observation that in two fetuses he had seen bands running to the umbilicus, which were probably omphalo-mesenteric vessels. He had moreover seen a case of adhesion of intestine to a tuberculous gland leading to longitudinal torsion.

RUPTURE OF THE RIGHT BRONCHUS.

Dr. HECTOR MACKENZIE exhibited this specimen from a boy who was run over by a van; there was no fracture of ribs, and he could not explain the result. Empysemata and pneumothorax ensued. The rupture was half an inch long and longitudinal in direction.

TRAUMATIC SEPARATION OF THE EPIPHYSIS OF THE GREAT THUMB-ARTER.

Mr. J. HUTCHINSON, jun., remarked upon this, that it was due to direct violence—a fall from a tree—in a lad aged 16 years; he lived ten weeks, and the accident was not diagnosed, as the patient could stand and raise the limb. The detached epiphysis was found after death attached to the shaft by bands of peritoneum.

LIVERPOOL MEDICAL INSTITUTION.

CHAUNCEY PUSEY, F.R.C.S., President, in the Chair.

Thursday, November 28th, 1895.

VIENNA DRINKING WATER.

Dr. HORN (M.O.H.) asked a question, of which he had given notice, as to whether any member of the Institution had had experience of the alleged deleterious effects from the use of

Vienna drinking water. He stated that so far as his investigations enabled him to judge, the one or two allegations concerning illness due to the use of the water were absolutely destitute of any foundation. In one of them the Vienna water was not supplied to the house in question at the time the alleged mischief from its use arose. A short discussion ensued, but no one had any adverse comment to make in reply to the question.

PITYRIASIS RUBRA.

Dr. STEPHEN TAYLOR showed a case of this disease. It was the patient's second attack, the skin having remained quite free from any eruption during the interval. The first attack occurred in 1892, and was secondary to a psoriasis of many years' duration. The patient was admitted into the Skin Hospital in March of this year on the recommendation of Dr. Carter. The treatment adopted was of a soothing character until and for some weeks after the temperature had become normal. Prolonged daily baths of several hours' duration were given, the water being at the temperature of 95° F. After each bath the patient was anointed with an ointment of glycerine of lead and vasoline equal parts, with the addition of a drachm of pyrene to each ounce. In August, the scaling having ceased, and the redness still remaining, an ointment of chrysophanic acid, 10 grains to the ounce and afterwards increased to 20 grains to the ounce, was rubbed in night and morning, and the patient was allowed out of bed. The effect of the chrysophanic acid was to cause the rapid disappearance of the redness, except in a few isolated patches; these were painted with pure liquid tar, and finally cleared. Quinine in large or small doses was continued almost the whole time. On one occasion a thyroid extract was given, this certainly aggravated the disease; on another iodide of potassium, which seemed to depress. The patient was shown at the meeting, perfectly well, the skin being pale, smooth, and soft.

Mr. RICHMOND LEIGH asked Dr. Taylor if he had found pityriasis rubra specially fatal. In a table of some 23 cases published in the *British Journal of Dermatology* by Dr. Stephen Mackenzie there were 3 deaths. Half of these cases were primary, and one of the deaths was in a case secondary to pemphigus foliaceus, a most fatal disease.

Dr. CARTER and ALEXANDER also made remarks on Dr. Taylor's case.

THERAPEUTIC ACTIONS OF OXYGEN.

Dr. MACALISTER related two cases in which oxygen had proved very serviceable. One of them was a case of uræmic coma associated with lividity; the patient almost at once gained consciousness when the oxygen was administered. The other was a case of morphine poisoning, and artificial respiration was necessary until the gas was given, when the respiratory function was restored and the cyanosis of the face, lips, and extremities was greatly relieved. In both cases recovery was complete.

A LIFE TABLE FOR LIVERPOOL.

This paper was by Dr. HUGH JONES and Dr. S. G. MOORE. After describing the method adopted by the authors in the construction of the table, it was shown that a considerable saving of life had been effected since the first life table was prepared by Dr. Farr in 1843. A reduction had taken place in the death-rate at all age groups, with a consequent higher expectation of life at all ages. The life table, based upon the figures for 1881-90, showed that the expectation of life at birth was 34.2 years, compared with 41.3 years for England, 31.7 for Manchester, and 35.2 for Glasgow. The diminished mortality had resulted in a considerable addition to the useful years of life, that is, between 20 and 65 years, amounting to 2,500 years of life per 1,000 births. It was further shown that the chief incidence of the excessive mortality in Liverpool was at the earlier ages, though, compared with England and Wales, the mortality was high at each age period. The authors pointed out that the enlargement of the city boundaries, by which a large suburban area is being absorbed, would result in an apparent diminution in the death-rate, but that this diminution would not of necessity imply any improvement in the sanitary condition of the city, nor in the vitality of the inhabitants.

Dr. HORN complimented the authors on the pains taken in constructing the life table, and, in criticising it, indicated directions in which elaboration was necessary before the table would add materially to knowledge upon the subject. Notwithstanding that the duration of life was shorter amongst dwellers in cities than amongst dwellers in rural districts, insurance companies drew no distinction. This circumstance suggested that the mortality was not excessive in the insuring and thrifty class, but amongst the vast labouring population. The inclusion or exclusion of rural areas in urban registration districts was a most important factor in modifying the death-rates of cities.

MIDLAND MEDICAL SOCIETY.

T. EDGAR UNDERHILL, M.D., President, in the Chair.

Wednesday, November 20th, 1895.

EXOSTOSIS OF FEMUR.

MR. J. T. J. MORRISON showed a specimen of exostosis of unusual size, which he had removed from the lower end of the left femur. The patient, a collier, aged 22, had been aware of the swelling for sixteen years. It had not interfered with locomotion or caused any pain, but it had led to his rejection as a candidate for the police force. Mr. Morrison briefly discussed the etiology of cancellous exostosis springing from epiphyseal cartilage; and remarked on the advantage of operating by the bloodless method, and of dressing the wound without drainage before removing the Esmarch tube. In the present case the bony pedicle had been chiselled through. The deep wound had healed in a few days by first intention, and the patient was now active on police duty.

CASES OF SKIN DISEASE.

DR. LESLIE PHILLIPS showed: (1) A case of lymphangioma circumscriptum cutis in a girl aged 17. The patch was situated over the right scapula, and was stated to have been of six months' duration. It was the size of a small hand, fawn or straw coloured, and consisted of aggregated, raised, flattened, resisting vesicles, almost verrucous in character. Over much of the eruption vascular tufts are seen, giving it an ecchymosed appearance in places. The vesicles when punctured exuded lymph. There were no subjective symptoms. The patient had red hair, and the angles of the mouth were scarred. The exhibitor expressed doubt as to the reliability of the reputed duration of the disorder. As the eruption was out of sight and did not give rise to inconvenience, it was probable that its onset was not accurately observed. (2) A man with lichen ruber planus of three months' duration, which began acutely as an eruption indistinguishable from patchy erythematous-squamous eczema—a character which still persisted in some of the lesions.

CYSTIC OVARIAN TUMOUR.

DR. MALINS showed a large cystic ovarian tumour, the chief peculiarity of which was two broad pedicles. The ovaries were firmly united, probably from pelvic pressure in early growth; they had increased rapidly in size, one large cyst reaching up to the liver on the right side. The patient was single, aged 36, and was in good health up to June. A week before admission to hospital she had been tapped, 80 ounces of fluid of specific gravity 1019 being evacuated from the cyst on the right side. The pedicles were tied in several divisions, with prepared silk. Recovery was without incident.

DERMOID OVARIAN CYST.

MR. HEATON showed (for Mr. LAW WHEB) a dermoid ovarian cyst removed from a woman, aged 40. It contained the usual pultaceous fatty material found in such cysts. Attached to the cyst wall at one point was a portion of a jaw, having four well-formed teeth firmly fixed in it. They resembled the incisor and premolar teeth of a child of 6 years old. From another point in the cyst wall there grew a long tuft of long silky hair, some 4 or 6 inches in length.

UNIVERSAL PURPURA.

MR. PROMER showed a patient with a purpuric eruption covering the entire body.

RUPTURED TUBAL PREGNANCY.

MR. GAGGER showed a specimen of ruptured tubal preg-

nancy. The patient, aged 39, had had five children born alive and one miscarriage, the latter seven months ago. Since then she menstruated regularly every five weeks. She lost some blood on September 18th, this being the time when she expected to menstruate. On September 19th she had some abdominal pain, and on September 22nd she felt sudden violent abdominal pain, vomited, and became collapsed. Laparotomy was performed twelve hours after onset of symptoms. The pelvis and lower part of abdomen were full of blood. A left tubal pregnancy, which had ruptured, was found. The broad ligament was ligatured with silk, and the tube removed. The abdomen was cleaned by sponging. After the operation the patient had a severe attack of bronchitis, but had no abdominal symptoms, and was discharged cured on October 24th.

PARIS HOSPITALS.

MR. WILLIAM THOMAS read a paper entitled Notes on a Paris Hospital Visit. The hospitals visited were the Hôtel-Dieu, Laennec, and one of the hospitals for sick children. He described the wards, and contrasted them somewhat unfavourably with those of English hospitals. He spoke with approval of the system of "consultations" instead of out-patient practice, and described several operations which he saw performed, noting some points which might give rise to discussion.

ANATOMICAL SOCIETY OF GREAT BRITAIN AND IRELAND.—The annual general meeting of this Society was held at Guy's Hospital on November 22nd. Professor Thane was elected President in place of Professor Cunningham. The Treasurer's account showed a balance of £76 2s. 6d.—Dr. G. F. MALLORY read a paper on the Topographical Anatomy of the Fourchette. He pointed out the discrepancies in the descriptions of this part in different textbooks, and gave statistics from the observation of 397 patients attending his out-patient department. The most important of these showed that in about 15 per cent. the fourchette was formed by the united posterior extremities of the labia minora, while in the rest it was a fold of skin apparently uniting the posterior extremities of the labia majora.—Mr. F. G. PARSONS read a paper and showed drawings of a Rare Form of Parasitic Fetus, lately added to the Museum of the College of Surgeons. The paper contained an account of the different systems.—Mr. A. KERR read a paper upon the frequent occurrence of a Divided Inferior Vena Cava in the Genus *Hylestotes* (Gibbons). In it he discussed the development of the veins of the abdomen, and criticised Hochstetter's views.—Mr. BIGGINS showed a series of specimens illustrating the true capsule of the knee-joint.

NORTH-WEST LONDON CLINICAL SOCIETY.—At a clinical meeting on November 20th, Dr. J. H. STOWERS in the chair. Dr. R. F. GILL read notes of a case of Pleuritic Effusion and Pulmonary Cancer.—Mr. C. G. BRONIE showed a case of Nævus treated by Electrolysis, and a case of Congenital Dislocation of the Hip; Dr. GUTHRIE a case of Plumbism and Menoplegia; Dr. CAGNEY one of Telangiectasis of the Face; Mr. W. H. BATTLE, Bullet Wound of the Skull in a Would-be Suicide, and Intestinal Obstruction by a Large Gall Stone; Dr. STOWERS a case of Epithelioma of the Back and one of Tinea Versicolor; Mr. MAYO COLLIER a series of cases of Nasal Obstruction; Mr. JACKSON CLARKE a case of Hallux Valgus and Hammer-toe.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—At a meeting on November 26th, A. BRONNEN, M.D., President, in the chair, Dr. HORSFURN gave a demonstration of microscopical specimens illustrating (1) Typhoid Bacilli in Spleen and in Ulcer of Intestine; (2) the Deposition of Iron Salts in the Kidney and in the Liver in cases of Pernicious Anæmia and in Lead Poisoning; (3) Cylindroma of Cervix Uteri.—Dr. S. LODGE, jun., showed two patients with Hemianopia.—Dr. CAMERON showed a patient suffering from Progressive Muscular Atrophy. There was wasting of the muscles of the arms, hands, and legs; deltoids not affected; knee-jerks brisk. The differential diagnosis of the case was discussed. Dr. GUYER, Dr. EVANS and Dr. BARAGLIATI made remarks, and Dr. CAMERON reported.—Dr. A. BRONNEN showed two patients with

whom he had operated for Mastoid Disease.—Mr. HOBBOCK read a paper on Three Cases of Hernia with Unusual Complications. In the first case the cause of the trouble was a small tumour in the mesentery, which blocked up the inguinal canal and prevented the reduction of the hernia. In the second case a half twist of the mesentery was found, and in the third case the cæcum formed part of the sac wall.—Dr. MAJOR read a paper on the Diagnosis of Hystero-Epilepsy and the Treatment of the Paroxysms. The differential diagnosis between epilepsy and the hysteroid attacks was considered, the involuntary passage of urine, biting of the tongue, and the formation of petechiæ pointing to true epilepsy. The treatment recommended for the hystero-epileptic attack was (1) to compress the nose and mouth for thirty seconds, (2) stramonium, (3) apomorphine, &c. &c. hypodermically. Dr. CARTER laid stress on insensibility as pointing to epilepsy. Dr. MANTLE would watch the temperature, and look upon fever as indicative of true epilepsy. Mr. HOBBOCK and Dr. FARRAR made remarks, and Dr. MAJOR replied.

KIDDERMINSTER MEDICAL SOCIETY.—At a meeting on November 22nd, Mr. W. MOORE, President, in the chair, Mr. J. L. STRETTON read notes of the following cases: Appendicitis in a farm labourer aged 19. An operation was performed, and the appendix, which was found perforated near the base, was ligatured, removed, and the stump sutured. The man died thirty-six hours after the operation. A limited necropsy disclosed a quantity of pus in the right iliac region. The appendix removed contained a faecal concretion. Notes were also read of a successful case of Operation for the Results of Injury to the Shoulder; of a case of Congenital Contraction affecting the index finger of the right and the middle of the left hand, and resembling in appearance Dupuytren's contraction, in a child six weeks old; and of the case of a quarryman, aged 24, with a piece of Granite in the Anterior Chamber of the Eye.—Mr. W. HOBSON MOORE described a case of Carbonic Oxide Poisoning in a young healthy bricklayer, who was at work pointing the defects in a retort which had not been used for some time. His mate left him for a few minutes, and found him unconscious on his return. When seen by Mr. Moore he was quite dead, and all efforts to restore animation were unavailing. The only peculiarity noticed about the body was the salmon-pink colour of the cheeks, which extended to the chest and arms. On raising the legs a suffused appearance of the face was produced. At the necropsy two days later the pink colour was still quite distinct, and the muscles when cut into exhibited a bright colour; the blood was fluid and very bright; with a 30 per cent. solution of caustic soda red stringy clots were produced. The organs of the body were healthy, but all exhibited the peculiar colour. The gas authorities denied the possibility of carbonic oxide poisoning, but Mr. J. L. STRETTON, who attended the post-mortem examination on their behalf, strongly supported Mr. Moore's view. It is probable that in stripping some of the decayed places or in moving some of the rubbish admitted to be on the floor of the retort, the men liberated some of the gas, a very small quantity of which produces a fatal result.—Mr. DAVIES showed the spleen and Internal Organs from a case of Leucocythæmia in a female, aged 19 years, admitted under Mr. J. L. STRETTON, in a married state, though she had been ill for only seven days. Mr. DAVIES also read a paper entitled Rough Notes on Clinical Treatment.

PROPOSED REGISTRATION OF MIDWIVES IN NEW SOUTH WALES.—A Bill "to promote the better training of women as midwifery nurses and for their registration as such" was introduced into the Legislative Assembly of New South Wales by Dr. GRHAM on September 11th. The Bill provides for the examination and registration by the Board of Health of women who desire to act as midwifery nurses. From and after twelve months from the date of the establishment of the Midwives' Register no woman shall be entitled to receive any fee or charge in court for attendance or service rendered as a midwife, unless such woman be registered under the Act. Section 2 of the Bill defines a midwifery nurse as "a woman who undertakes to attend in cases of natural labour." It does not, however, define "natural labour."

REVIEWS.

THE LIFE OF SIR HENRY HALFORD, BART., G.C.H., M.D., F.R.S., PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS, &c. By WILLIAM MUNK, M.D., F.S.A. London: Longmans, Green and Co. 1895. (Cr. 8vo, pp. 300. 12s. 6d.)

THE extraordinary position attained by Sir Henry Halford has always been something of a puzzle to succeeding generations, and we turn, therefore, to this work—issued with the imprimatur of the Royal College of Physicians—with the hope that Dr. MUNK may help us to a solution. Halford's career and character presented many contrasts. He was the fashionable physician of his day—in fact, he might almost be called the type of a fashionable physician—yet he was President of the College of Physicians for twenty-four years. He guided it through the crisis in its affairs which attended the removal from Warwick Lane to Trafalgar Square, yet he induced it to institute the evening meetings at which lectures on medical topics were delivered to popular audiences, an undertaking foreign to the general policy of that somewhat austere body. His hospital experience was small; he was appointed physician to the Middlesex Hospital when 27 years of age, and resigned the office seven years later; yet he sprang into large consulting practice at a very early age, and he was appointed Physician Extraordinary to the King when he was 27.

The achievements of his life were rather those of an eloquent reader of Latin orations and a neat turner of epigrams and verses in the same polite language than those of one who was anxious to make serious contributions to medical knowledge. He became a country squire by right of inheritance, made an aristocratic marriage, entertained royalty at his country seat, and evidently enjoyed the position to the full, yet he was a very hard-working physician in London, and almost died in harness.

One main element in his success was the tact with which he maintained himself as, in the literal sense of the words, physician in ordinary to the Royal Family through three reigns. When his intimate relations with the Court ceased at the beginning of the present reign, his practice fell off so much that he had, according to Dr. MUNK, to find another and occupation in the composition of Latin verses. His repeated re-elections as President of the Royal College of Physicians were, in part, at least, indirectly due to the same cause. It was through his influence with the Court and leading politicians that a grant of the site in Trafalgar Square was made to the College, but it was characteristic of his energy and determination of character that he by no means rested satisfied with this success, but devoted his best efforts to finding the funds necessary for erecting the building and to the management of the affairs of the College. Another, and the main element in his success was that he felt none of the scepticism as to the value of drugs which is so common at the present day. Dr. MUNK gives on this head a very illuminating quotation from Dr. Marshall Hall. Sir Henry Halford, we are told, "was remarkable for his fertility and invention in regard to remedies. This fertility in resources is not, perhaps, the highest or most scientific branch of medicine, but it is indubitably that which, if judiciously applied in practice, affords the greatest solace and benefit to the patient, and may therefore be regarded as the highest faculty which a physician can possess in the actual exercise of his Art." Added to this, Halford displayed an absolute loyalty to what he conceived to be the best interests of his patient, sometimes under circumstances of a most trying nature. A very nice point in medical ethics, indeed, arose on more than one occasion during the course of his attendance on several members of the Royal Family. This was how far a physician is entitled to conceal from a patient the gravity of the illness if the revelation, in his opinion, will have an unfavourable effect upon its course. The difficulty of a decision was in these cases increased by the necessity of making public some statement as to the actual condition. Halford throughout acted with great discretion in his relations both with the other members of the Royal Family and with the Government. He appears to have been guided by the principle that even in the course of

a fatal malady no direct communication of the expected issue should be made to the sufferer so long as the physician himself entertained any "hopes of administering the resources of our art to him with good effect"—that is, as the context shows, while there was any prospect that treatment could produce even a brief improvement. Again, in dealing with this subject in an address to the Royal College of Physicians, he says, speaking of the proper conduct of a physician in the issue of bulletins "when his patient is of so elevated a station that his safety becomes an object of anxiety to the nation": "He will not write one word which is calculated to mislead, but neither ought he to be called upon to express so much as, if reported to the patient, would destroy all hope and hasten that catastrophe which it is his duty and their first wish to prevent." In the case of ordinary patients he held that it was better that the probable termination of his malady should be communicated to the patient by his friends. "They do so," he said, "without destroying his hopes, for the patient will still believe that he has an appeal to his physician beyond their fears."

There are many other topics which would afford matter for interesting discussion, but we have left ourselves little space to speak of the manner in which Dr. Munk has discharged his task. We have already said enough to show that he has written a most interesting volume. He has given a vivid picture of the life and character of a remarkable man, and has thrown many sidelights on the position of medicine in this country in the early part of the century.

We are rather disappointed to find so few letters from Sir Henry Hallford's distinguished contemporaries: for them we could well have spared some of the not very interesting royal epistles with which Dr. Munk has rather encumbered his pages. Nor can we sympathise with Dr. Munk in his regret that Sir Henry Hallford yielded gracefully to the necessity for extending the borders of the Royal College of Physicians by the admission to the Fellowship of graduates of universities other than those of Oxford and Cambridge. It is at least a curious commentary on the alleged dangers of the course that of the nine physicians freely elected by the Fellows to the Presidency since the death of Sir Henry Hallford, four have been graduates of London, Edinburgh, or Aberdeen, and we may add that the erudite author of so many works dealing with the history of the College would himself apparently have been excluded had the barrier been maintained.

TUBERCULOUS DISEASE OF BONES AND JOINTS, ITS PATHOLOGY, SYMPTOMS, AND TREATMENT. By W. WATSON CHEYNE, M.B.Ed., F.R.S., F.R.C.S., Professor of Surgery in King's College, Surgeon to King's College Hospital and Paddington Green Children's Hospital. Edinburgh and London: Young J. Pentland. 1895. (Demy 8vo, pp. 374, 63 engravings. 14s.)

This work deals with a subject of absorbing interest to surgical practitioners, by reason on the one hand of the frequency and serious results of articular and osseous tuberculosis, and, on the other, of the great advance that has recently been made in the pathology and the treatment of these affections. Mr. WATSON CHEYNE has exceptional claims as a teacher of this branch of surgery, as he is not only well acquainted with the work of Continental authorities, but has himself done much both in the laboratory and in the hospital ward to add to our present knowledge of the matters which are here discussed.

The first part, dealing with the pathology of tuberculous diseases of bones and joints, is based on the author's Astley Cooper Prize Essay, modifications having been made in accordance with the results of subsequent research; and the second part, which is devoted to their treatment, describes that which Mr. Cheyne has himself found best, and which is now followed by those modern surgeons who have paid special attention to these morbid conditions.

In discussing the very doubtful question of an essential histological element of tubercle Mr. Watson Cheyne, agreeing with Baumgarten, holds that such element is to be found in the epithelioid cell, which is constantly present in tubercles and tuberculous tissue, and bears a constant relation to the

tubercle bacillus. Many, however, will be disposed to doubt whether the presence of this element in morbid structures can be regarded as a strict criterion of its tuberculous origin; and, indeed, it is acknowledged here that the characterising features of epithelioid cells with regard to tubercle consist not so much in their form as in their arrangement and abundance, and in their life-history. With regard to the difficulty experienced by many observers in making out the tubercle bacillus in tuberculous joints and abscesses, and the scarcity of these organisms when found, the conclusion is arrived at, after very careful investigation, that they can usually be seen after sufficiently careful and prolonged search, and, further, that present methods of staining do not permit us to determine the numbers present. The somewhat complicated description of the different forms of tuberculosis in bones and joints would seem to indicate that further and more extended pathological research is needed to permit of a clear and comprehensive classification of the apparently diversified phenomena presented by this disease.

In some interesting chapters on the non-operative treatment of osseous and articular tuberculosis the author insists on the value of rest and extension, and asserts that counter irritation—particularly the use of the actual cautery, though now rejected and, indeed, derided by many—often results under certain conditions in marked improvement. In dealing with Koch's tuberculin treatment, whilst making no mention of its indications in cases of joint disease, he expresses the opinion that this method in pathology has been unduly discredited and too hastily abandoned. In his remarks on the operative treatment of tuberculous affections of the larger joints, the indications and contra-indications of which, together with the selection of method in each case, are most carefully considered, Mr. Cheyne points out that the danger of arthrectomy and excision is greater than that of amputation. Notwithstanding the attempts that have recently been made to preserve the articular ends of the bones in the operative treatment of tuberculous joints, excision as at present performed is advocated as the preferable method in most instances in subjects who have reached full growth.

The second section of this book presents an instructive review of the symptoms and treatment of tuberculous diseases of joints and bones, which will be found of great service to the practitioner, both for reference and careful study.

TRATTATO DI PATOLOGIA E TERAPIA CHIRURGICA GENERALE E SPECIALE. [A Treatise on Surgical Pathology and Therapeutics General and Special.] Per Professor FRANCESCO DURANTE, Direttore della Clinica Chirurgica della R. Università di Roma. Vol. I, with 169 original illustrations in the text. Rome: Società Editrice Dante Alighieri. (Large 8vo, pp. 576, viii. 15 lire.)

THE appearance of the first volume of Professor DURANTE's work on surgery is a very important event for the Italian school of surgery, for up to now no complete modern work on surgery written by an Italian has been published. We, therefore, have taken up this volume for review with unusual interest, as we were anxious to know the present position of surgery in Italy, as expounded by one of the greatest surgeons in that country. It is known that within the last two decades a distinct and great advance in medical and surgical science has taken place amongst the Italians, and this volume is a remarkable proof of this fact.

The work, when completed, will consist of three volumes, extending to some 2,000 pages. The first chapter, which is devoted to inflammation and its types, includes an excellent summary of present knowledge as to pathogenic bacteria, particularly in relation to the phlogistic process. The author defines inflammation as "that typical and transitory nutritive activity determined by special micro-organisms." He then proceeds to deal from the phlogistic process to the pathological changes which take place in the regeneration and reintegration of tissues. The etiology, pathological anatomy, symptoms, and treatment are admirably discussed.

The second chapter—on Surgical Fevers—opens with general considerations on the subject, and then pyrogenic agents and the various forms of surgical fever are described. The clac-

tization and complications of wounds are next discussed; and the remaining two-thirds of the volume deal with tumours. Taken as a whole, this is the most important portion, as it contains a very large amount of original matter, as might be expected from so distinguished a pathological histologist as Professor Durante. It opens with a brief history of the classification of tumours, in which, whilst giving due credit to Virchow and others the author, basing his facts on original observations, does not blindly follow any of them. He maintains "that for a diseased product to be called a tumour it is necessary that it be generated from cellular elements which multiply continuously, and endeavour to reproduce a physiological type which they do not always reach." When this diseased product is not of new formation, or is arrested in its development, he does not consider it a tumour, although it may have the external shape, and its elements may be analogous to those of true tumours. He, therefore, excludes inflammatory products, cysts by retention, hypersecretions in pre-existing cavities, and animal parasites from the class of tumours. In a short review it is impossible to follow Professor Durante in his classification of tumours, which is founded on an anatomico-physiological basis in contradistinction to the clinical basis adopted by Billroth. We must refer the reader to the work itself, in which he will find plenty of food for thought, and perhaps for criticism.

The volume is beautifully illustrated, well printed, and its style is concise, clear, and eminently logical. In conclusion, we have no hesitation in saying that, if the forthcoming volume equals this one the work will deserve to rank with the most scientific, philosophical, and practical works on surgery at the present time.

A MEDICO-TOPOGRAPHICAL ACCOUNT OF JEYPORE. By Brigade-Surgeon-Lieutenant-Colonel T. HOLBURN HENDLEY, C.I.E. Calcutta: Central Press Co. 1895. (Cr. 4to, pp. 128, with maps, diagrams, and tables.)

JEYPORE is one of the largest and most important independent Rajput states, and has gained a high reputation in India on account of the liberal and enlightened character of its rulers, and the very commendable efforts made by its sovereign to promote the comfort and well-being of his subjects. The late Maharajah Ram Singh was conspicuous among Indian rulers for his loyalty, his encouragement of art and learning, his benevolent administration, and the measures which he undertook to promote the physical welfare of his people, and under his successor, Maharajah Sawai Madho Singh, the state continues to flourish. Not least among the material benefits conferred on the inhabitants of the State and city of Jeypore have been the measures undertaken with a view to sanitary improvement and medical relief, and the work and institutions completed and founded during the past quarter of a century have been substantial and costly, and are now in full and beneficent operation.

Brigade-Surgeon-Lieutenant-Colonel T. H. HENDLEY has served for twenty years as Residency Surgeon, and for thirteen as Superintendent of Dispensaries at Jeypore. He is well known as a sympathetic expositor of Jeypore history and art, and better qualified than any man living to write such a report as this, in which the topography, climatology, vital statistics, prevalent diseases, sanitary conditions, and medical institutions of Jeypore are minutely dealt with. The report is one of a class which is very common in India. There is hardly a district or town of which some industrious civil medical officer has not compiled a record of all that is known of its hygienic and medical history. The Medical Board of the Company, early in the present century, called on its medical officers to prepare reports of this kind, and many of these contain most interesting information bearing on the public health and the conditions affecting it.

The author of the present report modestly hopes that it will be useful to his successors. It will be very useful to those responsible in the future for the sanitary and medical administration of the Jeypore State; but the report has a wider value, as representing what an enlightened and benevolent native ruler can accomplish, under good guidance, towards raising the standard of physical well-being and rational enjoyment of an Indian community. *O si sis omnes.*

CHRISTMAS BOOKS.

THE harvest of gift books and Christmas cards and of seasonable books of a more serious character suitable for presentation is this year larger than ever. So, too, is the crop of story books and of the holiday kind of religious publication.

Messrs. Smith, Elder, and Co. send us a new volume by the author of *Voces Populi*, under the title of *Lyre and Lance* (3s.), with 24 full-page illustrations. It is a story in scenes, reprinted from *Punch*, which will amuse everyone, and is a model cure for dyspepsia. A short story by Mrs. Humphry Ward, *The Story of Bessie Costrell* (2s.), will be a welcome present everywhere. The Rev. Harry Jones has numbered a long series of medical men of distinction among his friends and colleagues. In his *Reminiscences of Fifty Years* (1s.), he has much to say of Joseph Rogers, Anstie, Russell Reynolds, and others who worked cordially with him as a thoroughly sound-minded, cheery, and sensible clergyman, who put sanitary and social progress in the forefront of his work. Other publications from the same firm which will be found well worthy of notice, for all are by good authors and have solid merits, are *Off the Map* (6s.), by G. F. Browne; *The Grey Lady* (4s.), by Henry Selous Merriman; *The Coming of Theodora* (4s.), by Eliza Orne White; *Our Square and Circle* (3s.), or the *Annals of a Little London House*, by Jack Esel. *The Signora* (6s.), by Percy Andrene, has much medical matter in it. *Gerald Eversley's Friendship* (6s.), by the Rev. J. E. C. Weldon, has already reached its third edition.

The Religious Tract Society sends us a parcel of books which combine instructiveness with interest. Of such a character is *Lighthouses, their History and Romance* (2s. 6d.), by W. J. Hardy, F.S.A.; *The Hidden Beauties of Nature* (3s. 6d.), by Richard Kerr, F.C.S., with 59 illustrations, are lectures reprinted which will influence not a few to form collections of suitable objects of natural history, and to do some work with the microscope. Of the same character but more definitely of the textbook type is the *Popular Handbook to the Microscope* (2s. 6d.), by Lewis Wright. It has no element of novelty, but its contents are accurate and instructive. *Consider the Heavens* (2s. 6d.) is a popular introduction to astronomy by Mrs. William Aldis, well written, and carefully illustrated. *The Girls' Own Annual* (8s.), the *Boys' Own Annual* (8s.), the *Sunday at Home* (7s. 6d.), and the *Leisure Hour* (7s. 6d.) are now all classics, and well known to our readers. They fill one with astonishment at the extraordinary wealth of really good literature and attractive illustrations which they offer for the lucky boys and girls of this generation whose privileges far exceed those of an earlier date. They are all of them portly volumes of a really delightful character.

Messrs. Blackie and Son, Limited, have series of science textbooks, very well known and successful, among which this year must be included *Earth Knowledge* (2s.), a textbook of physiography, by W. Jerome Harrison, F.G.S., in its ninth edition, extended and revised in accordance with the 1895 syllabus of the Science and Art Department. In the same series is a small textbook of elementary inorganic chemistry, theoretical and practical, by A. Humboldt Sexton, F.I.C., F.C.S. (2s. 6d.), with a course of chemical analysis and a series of examples in chemical arithmetic, revised and considerably enlarged to meet the requirements of the syllabus of the Science and Art Department. *Food and its Functions* (2s. 6d.) is a textbook for students of cookery, by James Knight, M.A., B.Sc. No teacher of cookery can now secure a first class diploma without some knowledge of the chemistry of foods and the digestive processes, while the code for evening continuation schools liberally encourages the popular teaching of such subjects. This volume aims at supplying students in training with a complete manual of the theoretical part of their curriculum. Of story books of the more popular character we have from the same publishers *For Life and Liberty* (5s.), by Gordon Stables, M.D.; *At War with the Pontiac* (6s.), by Kirk Munroe; *The Tiger of Mysore* (6s.), a story of the war with Tippeco Saib, by G. A. Henty; *Hallowed Agha!* (4s.), by Hugh S. Leger; *Through Russian Snows* (15s.), a story of Napoleon's retreat from Moscow, by G. A. Henty; *A Knight of the White Cross* (6s.), a tale of the siege of Rhodes, by G. A. Henty; and *A Thane of Western*, by Charles W. Whistler (6s.).

From Frederick Warne and Co. come a bright little series of excellent books, prominent among which stands out *Two*

Little Pilgrims' Progress (6s.), a story of the City Beautiful, by the famous author of *Little Lord Fauntleroy*, which will certainly achieve great popularity. Others which should be mentioned are *Lanshire Idylls* (6s.), by Marshall Mather; *The Heart of Man* (3s. 6d.), by Silas K. Hoeking, F.R.Hist.S., which has reached its third edition; and *The Shuttle of Fate* (3s. 6d.), by Caroline Masters.

Thomas Nelson and Sons send a series of books entitled *In Far Japan* (2s.), by Mrs. Isla Sitwell; *A Lost Army* (3s. 6d.), a tale of the Russians in Central Asia, by Fred Wishaw; *Norland Tales* (2s. 6d.), by H. H. Boyesen; *How Jack Mac-henzie won his Epulettes* (3s. 6d.), a story of the Crimean war, by Gordon Stables, M.D. None of these, however, stand out of the common, and that by Dr. Gordon Stables is even below his usual merit, and this is saying a good deal.

Bentley and Co. send *At the Court of the Amir* (16s.), by John Alfred Gray, M.B.; it is a serious descriptive book, giving a very thorough, but not a very lively or picturesque, account of Dr. Gray's residence in Kabul. Many people would be curious to have a trustworthy sketch of the present state of things in a country which is still, for the most part, closed against Europeans, but Dr. Gray has, unfortunately, not the art of either seeing or describing things which are interesting.

Fisher Unwin send *The Riviera, Ancient and Modern* (7s. 6d.), with maps and plans, by Charles Lenthéric; translated by Charles West, M.D. It is not a new book, but newly translated by Dr. West, whose excellent English style does full justice to the original. It is an historical, physiographical, and archaeological study of the Riviera, which intelligent travellers will be glad to have, not only as a guide book, but as a compendium.

Among the Christmas numbers of the illustrated periodicals the *English Illustrated Magazine* deserves special mention for the beauty of its artistic contents not less than for the interest of its literary matter. The *Queen* offers a splendid and varied bill of fare, including a story by Bret Harte, in his best style, entitled "Barker's Luck." *Fule Tide* gives its readers a treat in the shape of a charming love story by "J." entitled "Ia." *Black and White* has a strong cast, including Antony Hope, Arthur Morrison, Robert Barr, and Harold Frederic, and the performance of all these well-known writers comes fully up to the promise of their names. *Pears' Annual* consists of the fifth and last of the series of Charles Dickens's Christmas stories, "The Haunted Man," with illustrations by Mr. Charles Greene, R.I. The three large coloured plates presented with the number are excellent examples of artistic chromo-lithography.

DIARIES.

Messrs. Collins issue as usual an extensive series of convenient diaries, amongst which may be mentioned the *Large Scribbling Diary* with a week at an opening, interleaved blotting paper, 2s.; the *Commercial Diary*, quarto size, interleaved blotting paper, 1s. The *Desk Diary* will be found of a handy form for the desk or table, and the *Tablet Diary* with one week on a page, octavo size, 6d., for suspension. The *Gentleman's*, *Lady's*, *Portable*, etc., are a new issue of the well-known series of diaries, bound in leather, some of them fitted with pencils and pockets, and varying in size to suit every requirement.

MEDICAL DIARIES.

Messrs. Hazell, Watson and Viney (London) publish two types of visiting lists. One of these, a new venture this year, is called *Hazell's Physicians' and Surgeons' Visiting List*, and can be obtained in limp cloth (5s. 6d.) or morocco tuck (5s. 6d.). The paper used for this list is thin and tough, there is space for 150 patients, and the visits for a month are, by means of a half page, shown in an opening. There are a number of useful tables of weights, etc., and other information, an alphabetical list of the doses of drugs in the *British Pharmacopoeia* and of many unofficial preparations, as well as the formulæ of the British Pharmaceutical Conference, and a combined calendar and water-potability table. *Smith's Physicians' and Surgeons' Visiting List* for 1896 is issued by Messrs. Hazell and Co. in various sizes and bindings, varying in price from 2s. 6d. to 5s. 6d. This publication has now reached its fiftieth year, so that its convenience must have been recognized by several generations of practitioners. It can be had either with or without a journal showing a week in an opening.

Messrs. John Wright and Co. of Bristol send us the third edition of their annual *Visiting List*. Certain minor alterations have been made, chief among which is that a blue cast has been given to the paper to increase its opacity. The page, by means of a half page, shows a month in an opening, and there is space for a cross account. It contains also much useful information in tables and other compressed forms. (In leather wallet cover, 5s. 6d.) The same firm issue for the first time this year a "perpetual" visiting list, which has the same general character as the annual list, but is undated; it may thus be used continuously from year to year until fail, which for some purposes will be a convenience. (In leather wallet cover, 5s. 6d.)

From Messrs. Duncan Campbell and Son of Glasgow we have received a *Medical Visiting Book*, also of the perpetual kind. It is extremely simple in arrangement, and would make a good surgery book. They have sent also a *Professional Account Rendered Book*, with tabular alphabetical index for the entry of monthly visits, and totals for the year. The two books are apparently intended for use together, the first showing the daily visits and midwifery engagements, the second the monthly and annual totals.

CARDS.

Messrs. Raphael Tuck and Sons have sent us a more than usually excellent collection of Christmas and New Year's cards, amongst which are their highly artistic black and white etchings. Amongst their humorous cards is the "Living Picture" series, which will certainly be one of the hits of 1896. There are also some particularly good calendars, comprising several new designs, such as "Tennyson's Heroes and Heroines" Calendar, and the "Browning," the "Whittier," and the "My Lady" Calendars; the "Britannia Yacht" Calendar, a perfect model of the Prince of Wales's famous yacht, marks the acme of daintiness and perfection. The whole series of cards, booklets, calendars, etc., are perhaps better than have ever yet been issued, and it is interesting to notice that, notwithstanding the prediction of the decline of the popularity of these pleasant mementoes of the season and the goodwill connected with it, the sale of Christmas and New Year's cards last year was larger than it has ever been.

REPORTS AND ANALYSES

AND

DESCRIPTIONS OF NEW INVENTIONS

IN MEDICINE, SURGERY, DIETETICS, AND THE ALLIED SCIENCES.

LIQUOR CARNIS COMPANY'S PREPARATIONS.

RENEWED examinations of samples of virol, marrol, liquor carnis, and malto-carnis, the well-known preparations manufactured by the Liquor Carnis Company, have shown that they continue to present the characters and properties claimed for them as being valuable nutrients for invalids and others. Virol and marrol being prepared from ox bone marrow and extract of malt—the former containing in addition the constituents of eggs—are from their palatable form and easy digestibility of great service in diseases where food containing a considerable proportion of fat is indicated. Virol *carnis* is also prepared to meet the requirements of cases in which sugar is undesirable. Liquor carnis, as claimed for it, is an uncooked meat juice, and has evidently been prepared by cold pressure, for an analysis of the sample submitted to us gave a copious coagulum on being heated, and every evidence of being a well-prepared meat juice. The addition of glycerine as a preservative overcomes the difficulty usually met with in keeping such articles as meat juice, whilst at the same time it renders the meat juice more palatable. Malto-carnis is a preparation containing meat juice, added in the form of liquor carnis, malt extract, and cream. The sample examined by us was a bland cream-like preparation, having a decided action on gelatinized starch. On examination it gave evidence of containing meat juice and cream extract blended in such a manner as to make a very palatable mixture, and

thus combining the digestive action of malt extract with the stimulating and nutritive properties of cocoa and meat juice.

HYPODERMIC SYRINGE.

Messrs. ALLEN AND HANBURY have submitted to us a new hypodermic syringe which seems to present certain distinct advantages. It consists of a graduated glass barrel with plunger, also made of glass, accurately fitted into it. The piston being of glass does not get out of order, even if not in regular use, as those made with packing of leather or asbestos are apt to do, especially in hot and dry climates. The needles are readily detachable, and the whole instrument is easily sterilised by boiling. Inside the metal mount is a

collar of asbestos, which prevents any leakage of fluid from the top. The syringe should be filled and emptied with water a few times to moisten the asbestos collar, and to fill up any little space between the surfaces of the glass. The syringes are made in 10-minim and 20-minim sizes; also of the capacity of 5 c.cm. and 10 c.cm. for the injection of diphtheria, tetanus, or any other antitoxin. Altogether the syringe is one of the best and most convenient that we have yet seen.

"ANTI-STOOP."

Messrs. ARNOLD AND SONS are the agents for the Carson Anti-stoop, for preventing or curing stooping habits. It consists of two steel arms connected at the back by a cross-piece, and passing up the back of the wearer to within about 3 or 4 inches of the neck, where they branch out on either side and come over the shoulders. At the extremity of the arms are attached padded blocks which, it is stated, press gently and uniformly upon the shoulders, gradually forcing them into their proper position. The excoriation and abrasion of the

skin caused by the pressure and friction of straps passing under the arm are said to be entirely avoided. Owing to the elasticity of the steel it will give way to any sudden movement of the wearer, instead of breaking or cutting into the flesh. It is claimed that it can be put on and adjusted by the wearer alone, there being no straps or bands to buckle at the back.

INFLUENZA IN LONDON.—It is reassuring to learn that the deaths from influenza in London last week were 11, against 15 and 11 in the two preceding weeks; 1 death occurred in West London, 2 in North London, 2 in East London, and 6 in South London, including 3 in Deptford. It is satisfactory also to know that the deaths from diseases of the respiratory organs in London (285) showed a considerable further decline from the numbers recorded in recent weeks, and were as many as 146 below the average.

REPORTS

ON

THE NURSING AND ADMINISTRATION OF IRISH WORKHOUSES AND INFIRMARIES.

SPECIAL COMMISSION OF THE "BRITISH MEDICAL JOURNAL."

X.—BALLYSHANNON WORKHOUSE INFIRMARY.

Our visit to this house was the first cheerful experience since the beginning of our commission in Ireland; it was a revelation of the possibilities of an Irish workhouse under humane and enlightened management. The town is beautifully situated on the Erne; the falls, up which we saw the salmon leaping, are near the fine bridge which, spanning the river, connects the two halves of the town. The workhouse stands on the southern side, on a hill overlooking town and river. Dr. Condon introduced us to the Mother Superior, whose keen enthusiasm in the cause of the poor forgotten workhouse inmates was indeed refreshing.

We were conducted first to

THE FEVER HOSPITAL,

which stands apart on the other side of the road from the rest of the house. Structurally it differs in no respect from other buildings of the same class; it has two storeys, with two small wards on each side of the middle staircase on the ground floor, holding four beds each; on the top storey there is but one long ward on either side of the landing. The nurse's rooms are built out behind at right angles to the block, this annexe containing also the kitchen and laundry. The whole building was quite clean and ready for possible patients. The ground floor wards are flagged, which always seems to us unsuitable for sick wards; the stones strike cold to the feet of the attendants, and make the wards more difficult to heat. Straw ticks on iron bedsteads are used in this division. The nurse is trained, and she has paupers for the service of the building, but they do not act as nurses. There are no baths in the block, nor waterclosets; commodes are not kept in the wards, the vessels being emptied outside as they are used. The walls are smooth, whitewashed, locker tables stand between the beds, and we noticed armchairs. Spacious grass courts both to the back and front of the hospital form cheerful recreation grounds for the patients. Crossing the road we returned to the workhouse, of which the whole administration is

ENTRUSTED TO THE NUNS,

the head of the community acting as matron, and working with the master, so that the infirm wards were under her supervision as well as the hospital. The infirm wards were the same in position and structure as in any other house, but their whole aspect was different. The walls were smooth, colour washed, and decorated with pictures; the floor was clean, the patients were washed, armchairs took the place of benches. Both men and women

LOOKED LIKE HUMAN BEINGS.

Each bed had its separate towel, and at the foot a little bag with soap and brush and comb. We informed the Superior that we had been told that the old people objected to be washed; was it so? "We found," she said, "a little difficulty at first, and the men were rather shy, but by the exercise of a little tact and consideration the objection was overcome, and now they prefer being clean; we have also got rid of the vermin to a great extent." We were told by some of the few visitors who penetrated into the house in the old days that it was necessary for a woman to take care that her skirts should not touch floor or beds if she would avoid carrying away with her lively evidence of her venturesomeness.

IRON BEDSTEADS

are used in this division, and also in the able-bodied quarters, and in the boys' and girls' dormitories. This is the first house we have seen in which these inmates did not sleep on the floor. The old people were mostly out of doors, in the

rouse themselves to a sense of their duty and responsibilities, and to remember that the pauper inmates of the workhouse are human beings. These are brave words, and we thank the editor for them. If the Irish press in general would enter with us into the arena and fight for those who have a right for themselves, we should soon see something done to improve the condition of the Irish pauper. We read with pleasure that the official inspector has severely condemned the cells used by the lunatics; his strictures—more scathing than anything we ventured to publish—come with all the weight of official censure.

MECHANICAL ROAD CARRIAGES: HORSEFLESH v. STEAM.

THE possibility of substituting for the costly horse carriage a mechanical vehicle which will do the same work at a cheaper rate naturally appeals to the doctor, especially to the country doctor; and, indeed, that medical practitioners are alive to the importance of the question is shown by the number of inquiries on the subject which have been addressed to this office. We believe, therefore, that many of our readers will be grateful for a little information on the subject of mechanical carriages, and will like to know just how the matter stands at the present time.

Of the advantages of mechanical over animal traction there can be no question. The mechanical horse, unlike his living rival, only eats when he is at work. He does not want his meals served with regularity when he is at home in his stable. His food costs a great deal less. He is never sick or sorry, never tired. He will go on all day, and if need be all night. He does not require a stable. He does not grow ill or die. He will not run away. He does not deposit ordure on the roads. On the other hand, he may break down. He may even blow up. He wears out (though very slowly), and he requires a certain amount of skilled attendance.

All this is on the assumption that a good mechanical horse can be found, and probably the questions our readers most desire to have answered are: How far is mechanical power available; or, at least, what prospects are there that such power will be available before very long? What will be the probable cost? What are the chief difficulties in, or objections to, its use? What sort of power will be the most convenient? These questions we will try to answer, in at all events a summary fashion.

LEGAL OBSTACLES.

First of all there is the legislative question. Locomotive engines on common roads can (under the Highways Act) only travel at a very slow speed, preceded by a man with a flag. Their wheels must have 3 inch tyres, and there are certain other conditions intended to prevent the roads from being damaged or horses from being scared. If a mechanical carriage is a locomotive these provisions obviously prevent its being used on a highway. But is it? It certainly is not a vehicle of the class contemplated by the framers of the Act, and it seems quite possible that in law it would not come under the Highways Act at all. A strong argument against mechanical carriages being so classed is found in a clause of the Customs and Inland Revenue Act of 1888, which includes mechanically-propelled carriages in the list of vehicles for which a licence has to be taken out, thus placing them on the same footing as ordinary carriages, and removing them from the category of road locomotives and traction engines. However, the cases which have been decided up to the present are against this liberal view, and until they have been upset or until fresh legislation puts matters on a reasonable footing mechanical vehicles can only appear on our roads on sufferance.

ELECTRICITY AS A MOTIVE AGENT.

Assuming these artificial hindrances to be cleared out of the way, what is to be the character of the mechanical carriage of the future? There are practically three sources of power available—steam, oil, electricity. The last-named, if practicable, would be the most convenient of all, but in practice it has been found the least successful of all three systems. In the recent French trials the electrically-propelled carriage failed entirely, though most elaborate and costly preparations had been made by its proprietor. Possibly, where ready means exist of charging a storage battery, electricity might be used to drive a private carriage, but only in

exceptional cases could such means exist, and then the carriage could never go more than a certain distance—say half a day's journey—from its station. Its battery once exhausted it would become as helpless as a steamer with a broken screwshaft, and nothing would remain but to tow it ignominiously home.

In the case of public vehicles, trams and omnibuses running from one charging station to another, the application of secondary batteries comes under different conditions, but these we are not concerned to discuss. As to primary batteries, no primary battery suited for work of this kind has as yet commended itself to the approval of electricians. The invention of one might go far to solve the question of mechanical road traction.

OIL ENGINES.

The successful competitors in France and the carriages recently shown by Sir David Salomons at Tunbridge Wells were all driven by oil engines, and the same class of motor is used in, at all events, the large majority of the vehicles now becoming popular in France and Germany. These engines are of the same type as the ordinary well-known gas engine, which is driven by a series of small explosions of mixtures of gas and air; but instead of gas they employ the vapour of light petroleum oil generated as required from a supply of such oil carried with the engine. They are by no means free from danger, and the benzolene which they require is a very unsafe material both to use and to store. The ordinary petroleum oil used for lighting purposes will not serve for the purpose. There is another form of oil engine, usually known as the naphtha engine, in which the oil vapour is used after the manner of steam in the steam engine, being condensed after it has served its purpose. These have been used both here and in America for the propulsion of launches; they are cheap, but more dangerous than the first mentioned class. We are not aware whether they have been tried for driving road carriages, but they are not likely to be so employed. All the oil engines give off an unpleasant smell of petroleum. They are of course absolutely free from smoke and steam. They can be started very quickly, as there is no delay for "getting up steam" as in the steam engine.

STEAM ENGINES.

Notwithstanding these advantages, and the practical success these oil motors have attained, the tendency of expert opinion in this country seems to be in favour of steam. Engineers seem to believe that a small steam engine

can be constructed which will work as conveniently and as efficiently as the oil engine. The lightest and most efficient steam engine yet made is certainly the one constructed by Mr. Maxim for his flying machine, and it is quite possible that a motor of this class will prove the most suitable for road propulsion. The boiler for such an engine would be fired with petroleum such as is now used for lamps. For the present, however, the oil engine is the best motor available, though possibly the liberal prize offered for the best road carriage by *Engineering* may bring out something better. In order to give our readers an idea of the general arrangements of a mechanical carriage we reproduce (by the courtesy of the editor of *Engineering*, an illustration of a steam carriage in which the source of heat is coke.

The carriages of this pattern are designed and manufactured by M.M. Serpollet, of Paris. The latest type of this carriage is shown in the diagram. The furnace and steam generator (a) is shown at the back. The reservoir of water is under the seat of the carriage. The steering apparatus, brake, etc., are shown in the body of the carriage (b, c, d) near the hand. The boiler consists of a series of straight tubes of very thick steel having in section the form shown in our second figure. Water is admitted into these tubes at the

base of the boiler near the firegrate. Here it is almost immediately converted into steam, which becomes superheated as it passes through the upper tubes to the steampipe leading to the motor (m). Very little water is admitted into this boiler, but the tubes, on account of their great thickness, are able to retain so much heat as to render them unaffected by any temporary variations in the intensity of the fire. The iron casing round the boiler is lined by refractory brick to check radiation of heat. The carriage weighs about 13½ cwt. when empty, and will carry a load of four passengers at the rate of nine to fifteen miles, or even twenty-two on favourable gradients, so it is said. It consumes about 3½ lbs. of coke a mile, and uses about one-tenth of a pennyworth of lubricating oil in the same distance. It is stated not to make much noise, to give no smoke, and to show no steam except when the atmospheric conditions are very unfavourable.

The motor, whatever type be selected, may obviously be fitted to a carriage of any sort. A tricycle with added motor is spoken of as being a delightful form of conveyance. The rider may rely entirely on the engine, or he may use his feet as a supplementary source of power, or he can put the engine out of gear and work the tricycle in the ordinary way. At present the carriages which have been exhibited are rather expensive; £200 or £250 appears to be about their price; the cost of the tricycle is given at £62; but it must be remembered that they are more or less experimental, and the cost will drop considerably when they come to be produced in large numbers and on a manufacturing scale. The present price, moreover, is regulated not by the cost of production, but by the demand for a novel and fashionable toy. Probably it will not be a very inaccurate estimate to say that a carriage fitted with a motor will cost something about the same price, or rather less, than a similar carriage and the horse or horses required to draw it. The cost of working seems to be something like a penny a mile.

On the whole there seems to be every reason to believe that there will soon be available for general use several types of mechanical carriage, any one of which can be driven by a person without much mechanical knowledge or skill, some of which will be moderate in cost, and all of which will be much cheaper in working than similar carriages drawn by horse power. At present, however, the regulations of the Highways Act block the way, and till they are removed we shall probably have to content ourselves with looking on at the progress made in other countries.

A TEACHING UNIVERSITY FOR LONDON.

AN influential deputation from institutions named in the report of the Royal Commission on the (Oresham University waited, on November 23rd, upon the Duke of Devonshire at the Privy Council Office, to urge that the Government should introduce at an early date a Bill similar to Lord Playfair's University Commission Bill, 1895, appointing a statutory Commission to carry out the recommendations of Lord Cowper's Commission, but with an added clause giving to all institutions or persons directly affected by any statute or ordinance proposed by the statutory Commission a right of appeal to the Privy Council.

Lord Kelvin introduced the deputation, whose views were

enforced by Professor RÖCKER on behalf of the London University, Dr. ALLCHIN for the Royal College of Physicians, Mr. HEATH for the Royal College of Surgeons, Sir G. YOUNG (University College), Dr. WALKER (King's College), Dr. FREDERICK TAYLOR (Medical Schools), the Rev. FRANK WHITEHORN (Chesham College), Sir H. ROSCOE, and Professor SILVANUS THOMPSON.

The DUKE OF DEVONSHIRE, in reply, said that he had listened with the utmost attention to the views expressed by those who had spoken. He believed the deputation was a very representative one, but he must make one reservation in regard to the large body of students, drawn from the whole British Empire, who could never avail themselves of facilities for university teaching in London, but who had in the past obtained from the London University in its examining capacity valuable guidance in their studies, and a highly-valued recognition of their acquirements. They would not expect that he should on this occasion commit the Government to any course. He had desired to learn what were the views of the bodies represented on the deputation, and it was equally his duty to obtain if possible an expression of opinion from the body of external students he had referred to. The Duke proceeded to refer to the differences of opinion on the scheme of a teaching university which had appeared in the Convocation of London University. He expressed the opinion that it would be a rather strong proceeding, that in order to create a teaching university a constitution should be imposed on the existing University against the will of Convocation, which, under its existing charter, possessed the right of imposing a veto on any alteration in its constitution. Professor Thompson said there was a majority of two to one in Convocation in favour of the scheme of a Statutory Commission. The Duke referred to certain amendments to the scheme which he understood were advocated by a majority of the existing graduates, and urged the expediency of doing everything that was possible to reconcile this opposition. If a Bill on the subject were presented to Parliament it was extremely desirable that it should come in a shape which would excite as little opposition as possible.

THE ANNIVERSARY CELEBRATIONS OF THE ROYAL SOCIETY.

ADDRESSES BY LORD KELVIN AND SIR JOSEPH LISTER.

ON Saturday, November 30th, St. Andrew's Day, the anniversary meeting of the Royal Society was held at Burlington House. The auditors of the Treasurer's accounts having read their reports, and the Secretary having read the list of Fellows elected and deceased since the last annual meeting, Lord KELVIN, the President, proceeded to deliver his address. Of four of the deceased members, Cayley, Neumann, Huxley, and Pasteur, he made special mention. Of the late Professor Huxley, the President spoke as follows: "The death of Huxley, one of my predecessors in the presidential chair of the Royal Society, takes from us a man who can ill be spared. During the fifty years since he sailed from England as assistant surgeon on board H.M.S. *Porpoise*, bound for a surveying expedition in the southern seas, he had been a resolute and untiring searcher after truth, and an enthusiastically devoted teacher of what he learned from others and what he discovered by his own work in biological sciences. His first contribution to science was a short note, communicated while he was still a student in the Charing Cross Hospital to the *Medical Times and Gazette*, describing a structure in the root sheath of hair, which has since borne the name of 'Huxley's layer.' It was followed by papers on the blood corpuscles of the amphioxus lanceolatus and on the anatomy and affinities of the family of medusae, for the British Association and the Royal Society; and several other articles on various biological subjects, all describing some of the work of the laboratory left him by his medical duties during his four years' cruise on board the *Rattlesnake*, which were sent home by him to England and published during his absence. It is to be hoped that the long series, thus so well begun, of papers describing skilful and laborious research by which knowledge was increased in every department of biology, will be given to the world in collected form as soon as possible. Even these purely

scientific papers contain ample evidence that Huxley's mind did not rest with the mere recording of results discovered by observation and experiment; in them, and in the nine volumes of collected essays which he has left us, we find everywhere traces of acute and profound philosophic thought. When he introduced the word "agnostic" to describe his own feelings with reference to the origin and continuance of life, he confessed himself to be in the presence of mysteries on which science had not been strong enough to enlighten us, and he chose the word wisely and well. It is a word which, even though negative in character, may be helpful to all philosophers and theologians. If religion means strenuousness in doing right and trying to do right, who has earned the title of a religious man better than Huxley? Of Pasteur, introduced as another name literally of world-wide fame, Lord Kelvin said: "Having been led to trace microbes as the origin not only of fermentation and putrefaction, but of a vast array of destructive blights happening to plants and animals—vine, silkworms, birds, cattle, and mankind—Pasteur was forced to take up the question, as of supreme practical importance, Whence came these microbes and what are their antecedents? Pasteur set about to trace the antecedents of every microbe he met with, and he found for it in every case a living thing, whether in the air, or in water, or in earth. During all the latter part of his life and to the end Pasteur devoted himself to biological research and to vigorous practical realisation of its benefits for the world." A statement of the work for which medals were to be conferred followed, the awarding of the Davy medal to Professor Ramsay being described as a crowning act of recognition of his work on argon and helium, which had already been recognised as worthy of honour by scientific societies in other countries. Lord Kelvin concluded his address by acknowledging the kindness he had received during his five years of office. Medals were then presented to Dr. John Murray for his services to biological science and oceanography in connection with the *Challenger* reports, and for his original contributions to the same; and the Davy medal to Professor William Ramsay, F.R.S., for his share in the discovery of argon, and for his discoveries regarding gaseous constituents of terrestrial minerals.

In the evening the anniversary dinner was held in the Hotel Méropole, when the newly elected President, Sir Joseph Lister, occupied the chair. A large and distinguished company sat down. In replying to the toast of "The Royal Society," proposed by Mr. SHAW LEPAYRE, the President took occasion to recall the deaths which had occurred during the year among those Fellows of the Royal Society who were members of his own profession. Among others he mentioned Sir W. Savory, a distinguished surgeon and a man of singular eloquence; Mr. Hulke, one of the most accomplished members of the profession, and at the same time a most eminent geologist; Sir George Buchanan, who was a fellow student with himself and a pioneer in sanitary science, rendering important service in that department; and last, not least, Thomas Henry Huxley. Huxley's claims to the admiration and gratitude of mankind were set forth fully in the great meeting recently held to do him honour, and Lord Kelvin, in his address in the afternoon, had further referred to them; but he should like to say a word with regard to Huxley's personal character, and to express the great admiration he had for that character. They might not all of them feel the difficulties Huxley had with regard to matters of supreme interest, but those very difficulties only made more striking his virtues, and well indeed would it be for mankind if all had his perfect truthfulness, his large-hearted benevolence, and in equal measure, if he might borrow Lord Kelvin's expression, the religion that consists in the strenuous endeavour to be and to do what is right. Again, he could not avoid expressing the grief he felt in common with the whole scientific world at the death of M. Pasteur, who was, perhaps, as conspicuous an example as the world ever saw of how pure science might lead to the conferring of incalculable material benefits on mankind. The first time he himself saw M. Pasteur was in his laboratory. It happened that on that occasion the great physiologist was good enough to demonstrate to him a fact of very great physiological importance. It could only be demonstrated upon a rabbit. A small incision was made. It was an operation involving really but little pain, but he well

remembered M. Pasteur's exclamation, "*Pauvre bête!*" From that he derived the impression that M. Pasteur was a man of tender heart, and that impression had been confirmed by all he had known since of him and his career. Little did those imagine who lightly spoke of M. Pasteur as cruel because some of his most beneficent work had required experiments on animals—experiments which, if the truth were known, involved but little suffering—how benevolent and humane a man it was whose character they thus ignorantly and lightly traduced.

THE BATTLE OF THE CLUBS.

At a meeting of the Dundee and District Branch of the British Medical Association, held on November 30th, the following resolutions were adopted:

Medical Aid Associations.—That it is derogatory to the dignity of the medical profession for any of its members to become medical officers to any medical aid association, and that no practitioner holding any such office should be eligible as a member of the Branch.

Medical Clubs and Friendly Clubs.—(1) That in this district there is practically no abuse as regards the wage limit. (2) That medicines being excluded no fee less than 2s. 6d. per annum per adult member be accepted, and that medicines being included the minimum fee be 4s. 6d. per annum. (3) That in all cases a fee be paid for examination of candidates, and that the minimum fee be 2s. 6d.

[This last clause was agreed to after a division. The Council were instructed to arrange a conference with the officials of the various friendly societies.]

Unregistered Dental Practitioners.—That in the opinion of this Branch, members of the medical profession ought not to administer anaesthetics for unregistered dental practitioners.

LITERARY NOTES.

Tins Rebman Publishing Company announce for immediate publication a new edition, revised and brought thoroughly up to date, of *A Textbook of Surgery*, edited by Wm. W. Keen and J. William White; a new work, *The Pathology and Surgical Treatment of Tumours*, by Professor N. Senn, and a new edition of the same author's *Principles of Surgery: A Textbook of Obstetrics*, edited by Dr. R. C. Norris and R. L. Dickinson (as art editor), with the help of sixteen collaborators. The same firm has just issued a new (third) edition in one volume, of Dr. J. V. Shoemaker's *Materia Medica and Therapeutics*.

The *Russisches Archiv für Pathologie, klinische Medizin und Bacteriologie* is the title of a monthly periodical, the first number of which will appear in January, 1896. The editor will be Professor W. W. Podwysotsky, of Kieff, who will have the leading scientific authorities in Russia as collaborators. It is intended to place the work of Russian investigators and clinicians before the medical world. Abstracts of the original papers will be given in French.

A new periodical devoted to cancerous diseases has just appeared in Paris. Its name is *Revue des Maladies Cancéreuses*, and it is published under the direction of Professors Duplay, Lannelongue, and Cornil. The editor is Dr. Ozenne. The new review will be published quarterly.

Since the death of Professor Moos, of Heidelberg, the *Zeitschrift für Ohrenheilkunde* (which is the German edition of the well-known periodical conducted by Professor Knapp, of New York) has been edited by Professor Körner, of Rostock, and Dr. Arthur Hartmann, of Berlin, the former having charge of the original contributions, and the latter of the reports of societies, etc.

Dr. Barney Yeo has an article entitled "Medicine and Society" in the *Nineteenth Century* for December. It was, we understand, delivered as an address to the Medical Society of King's College.

Mr. H. K. Lewis will shortly issue in his "Practical Series" *The Treatment of Pulmonary Consumption*, a practical manual by Drs. V. D. Harris and E. Clifford Seale.

Our Belgian contemporary, *La Flandre Médicale*, which was originally started as the organ of the profession in Ghent, has been so successful that, after transforming itself from a fortnightly into a weekly periodical, it has now changed its name to *La Belgique Médicale*, by way of indicating that it is no longer a local but a national journal.

BRITISH MEDICAL ASSOCIATION.

SUBSCRIPTIONS FOR 1895.

SUBSCRIPTIONS to the Association for 1895 became due on January 1st; and notice is hereby given, in accordance with By-law 5, that Branch Secretaries' subscription accounts close on October 31st, and all unpaid subscriptions must be forwarded after that date to the General Secretary, 439, Strand, London. Post-office orders should be made payable at the General Post Office, London.

British Medical Journal.

SATURDAY, DECEMBER 7TH, 1895.

THE ASSOCIATION, THE PROFESSION, AND THE JOURNAL.

OUR PROGRESS AND OUR PROGRAMME.

It has for many years been the custom in this annual number of the BRITISH MEDICAL JOURNAL, in which our programme for the ensuing year is set forth to the profession at large, to take our readers into our confidence and to discuss some leading features in our work during the past and our plans and forecasts for the immediate future.

This is the more useful and the more easy because for the most part our readers are also "our members"—members in common of the body corporate with which we are associated, and of which the JOURNAL is at once an exponent and a leader. The issue of the programme number throughout the profession has now for thirty years proved to be the chief recruiting agent of the Association, and the medium by which the greater percentage of the new members enter. To those who desire to possess the JOURNAL, but who for various reasons cannot be accepted as members, it is furnished at annual rates varying from 28s. to 32s. per annum; and of these there are now upwards of 2,000. But to all regular members of the profession of good standing the alternative is offered of acquiring the JOURNAL for a reduced annual payment of one guinea, which covers at once the cost to them of the JOURNAL and of all the other privileges of membership. It is of course impossible to assess these privileges at any money value, but they include the moral and social value of association and of the annual and other meetings, the powers arising out of organised and common action through a powerful and extended machinery, with an experienced and devoted general manager and secretary; the pride and honour of advancing knowledge by scientific grants; the convenience of a reading room and library; facilities for intercommunication and the activities of special organisations and committees, such as the Parliamentary Bills Committee, the Inebriates, Medical Charities, General Practitioners, and Therapeutic Committees, each pursuing stated public and professional purposes and supplied with funds from the surplus income which the JOURNAL provides, and which its continually increasing success annually magnifies.

In addition to these returns, for the reduced subscription of a guinea, and in addition to supplying the cost of conducting the central work of the Association in all its departments, the JOURNAL yields by its weekly receipts from advertisements and sales an annual sum of just upon £17,000

—a sum nearly equalling the total receipt from subscriptions, and sufficiently large to admit of putting aside a surplus, which has reached now the respectable sum of upwards of £40,000, and which is increasing from these various sources by an average annual increment of £3,000.

These satisfactory results have been achieved within a period of thirty years—since 1866. During the previous forty years, when the JOURNAL was small in size and attracted but a limited circulation, the total paying membership had hardly reached 2,000, and the accounts of the Association were with difficulty balanced; any expenditure on grants or committees had to be met by a special subscription. The actual membership is now over 16,000, and the subscriptions for 1894 were over £16,500, being eight times as large, while the JOURNAL has been developed to ten times its former size and contents without any additional charge to the members. The total circulation of the JOURNAL including those who cannot be allowed to become members, and who have, therefore, to pay 25 per cent. more than those who add membership to the other privileges of subscription, brings the total up to more than 19,000. We are able to look forward as confidently this year as in previous years to a further increment of the members of the Association from the distribution of the present issue beyond the bounds of the existing membership. Besides obtaining the JOURNAL at a reduction of 25 per cent. below its normal subscription price, the elected member obtains the satisfaction and advantage of joining a professional body which has now been developed into the most numerous and the most popularly constituted that has ever yet grown up in any profession. The Association does not aim at any financial profits or material and personal advantages; its constitution, as laid down by its founders, defines its objects to be:

The objects for which the Association is established are the promotion of medical and the allied sciences, and the maintenance of the honour and the interests of the medical profession by the aid of all or any of the following:

- (a) Periodical meetings of the members of the Association, and of the medical profession generally, in different parts of the country.
- (b) By the publication of such information as may be thought desirable in the form of a periodical journal, which shall be the journal of the Association.
- (c) By the occasional publication of transactions or other papers.
- (d) By the grant of sums of money out of the funds of the Association for the promotion of the medical and the allied sciences in such manner as may from time to time be determined on.
- (e) And such other lawful things as are incidental or conducive to the attainment of the above objects.

For these it was incorporated; to these it is by its form of incorporation limited; for these it has laboured and will continue to labour.

If we ask for the results of these labours we have only to look about us. The passage of the Medical Acts, the establishment of a Register and the protection of medical titles, and the existence of the General Medical Council; the unification of the profession in the three kingdoms, and the concurrent rights of practice in all parts of the kingdom; the remarkable elevation of the minimum standard of education; the prescription of a double qualification; the arrest of the "downward competition" of examining bodies—these are some of the larger results of the organised action of the Association in relation to internal organisation of the profession. They have transformed the profession, waited it, and raised its whole character and standard. In its

public relations, too, to it are chiefly due the Royal Sanitary Commission and the Public Health Acts. To the JOURNAL may be credited, among other things, the Infant Life Protection Act, the Notification of Diseases Act, the creation of the Medical Sickness Annuity and Life Assurance Society, the steady defence and successful advocacy of the rights and privileges of the medical officers of the naval and military services, great advances in the organisation and remuneration of the Public Health and Poor-law medical services, and many notable achievements in the amendment of the relations of the practitioners to the State. The scientific and clinical value of its original papers, reports, reviews, special commissions, and Epitome of Medical Literature are self evident, and have reached a standard never before or elsewhere attained.

The advantages of the Branch meetings and of the annual meetings are no longer in need of advocacy; they are among the most prominent reasons and uses of membership. The JOURNAL is the mainstay and backbone of the Association, but the most certain hope of increasing its stability and development lies in popularising, extending, and strengthening the activity and influence of the Branches, which are the constituent bodies of the Association and the electors of the Council.

We repeat that although the limits of possible extension among the dwindling outside circle of non-members and non-subscribers shrink every way in proportion to our increasing annual growth, yet the experience of past years leads us to anticipate that the period when this, our annual appeal, will cease to be fruitful in the large recruitment of new members is not yet at hand, for the value of the JOURNAL continually grows, while the price of the subscription remains at a guinea, as it was fixed sixty years ago, when both it and the Association were relatively small.

During the past year the increase in circulation has been no less than 800. The coming year will witness the debate in our columns, and in the Council and Branches of the Association, not only of many great questions of scientific and practical progress in medicine and surgery, of which our programme on the inset will give a few preliminary details, but also of many problems of administration and organisation of active present interest. For many abuses and needs the profession is powerless to seek or provide a remedy outside of the local or central representative organisations of the British Medical Association. Among these are the midwife question, that of the reorganisation of the General Medical Council, the organisation of successful opposition to the medical aid societies, the abuse of hospitals, and the rampant malpractices of quacks.

Time and unity, moderation, and good statesmanship are needed to deal with these difficulties: finally to dispose of them will need all the strength, intelligence, and combination of purposes of a great profession, the whole of which is practically active in its Branches, and through them represented on the Council of the Association. As are the Branches, so must and will be the Association. The constitution of the Association enables and requires the Branches to express their views through their representatives, and this is really the only intelligible and stable mode of constitution.

DR. PATRICK MURISON has been elected to represent the 5th ward of the City of Dundee by a very large majority.

THE PARLIAMENTARY BILLS COMMITTEE AND MEDICAL OFFICERS OF HEALTH.

If anyone wanted an object lesson of the multifarious activities of the British Medical Association, he could not do better than read the minutes of the Parliamentary Bills Committee, as published in the BRITISH MEDICAL JOURNAL of November 9th. This Committee has on many occasions done invaluable service, and as usually happens under such circumstances, its duties steadily grow. It has become the active intermediary between the Association, or indeed the profession, and the Government, and is constantly making itself heard by every department of the State on questions affecting medical interests.

At the meeting referred to, an ample bill of fare was placed before the members. The registration of nurses, the opening of workhouse infirmaries and lying-in hospitals for the teaching of male medical students in midwifery, the necessity of a further inquiry into the whole question of meat supply and inspection, the demands of medical officers of health for security of tenure in their appointments, the opposition to the registration of midwives, and the improvement of nursing in provincial workhouses and infirmaries, together with cases of grievance suffered by medical officers in the public services, formed a *menu* for the most omnivorous worker.

Other questions over and above these, of which the Committee has hitherto had the charge, such as the amendment of the Medical Acts, may, as they become more pressing, have to be dealt with by a smaller and more specialised committee, like the old Medical Reform Committee. Such a committee might also appropriately and usefully oppose any attempts to invade the rights of medical practitioners, like that attempted by the last Midwives Bill.

The Parliamentary Bills Committee is seen at its best in dealing with the administrative functions of the Government and in enlightening the official mind as to the real aims of State medicine. For example, the whole subject of the inspection of the meat and milk supply has been raised by the report of the Commission on Bovine Tuberculosis. In this connection there is work for the Committee, and medical counsel will be pre-eminently useful in suggesting the measures best calculated to save the community from the danger of a serious spread of tuberculous disease.

Security of tenure for medical officers of health in their appointments is a question on which real good has already been effected. Largely by the efforts of the Parliamentary Bills Committee permanent appointments have been secured for health officers in the metropolis and Scotland. In the early part of the year an important deputation, organised by the Parliamentary Bills Committee, made representations to the Local Government Board in favour of the universal application of this principle. The case was then stated in all its overwhelming strength, but the results have not yet been fully gathered. It must be borne in mind that until Parliament has time to amend the Public Health Acts the full measure of justice which the profession desires cannot be attained. The new Government will have the opportunity of doing this necessary piece of work. The late Government made an advance in this much desired direction by doing what it could to encourage the local authorities to make

longer or permanent appointments of health officers. The Parliamentary Secretary promised this much to the deputation of last March, and now the local authorities are always informed that it appears to the Board that in future, where a medical officer of health discharges his duties satisfactorily, the district council may consider whether it may not be desirable, on the renewal of the appointment, to appoint him for a term of years, if not permanently. This intimation, at all events, gives the right bias to the bodies newly constituted under the Local Government Act, 1894, and in a few instances it has already been followed by good effects.

We would urge upon medical officers of health everywhere to see that the hint of the Local Government Board is not overlooked. There can be no good reason why, in the interests of efficient administration, a health officer should be placed as regards the security of his appointment in a more precarious position than a clerk or any other official. There are overwhelming reasons on the other side. The delicacy of the health officer's functions, the intimate and intricate connections which his work has, not only with the well-being of the community but also with the pecuniary interests of influential property owners, make it imperative that he should be vigilantly shielded in the performance of his duty. The Parliamentary Bills Committee cannot do better than press the matter on the attention of the Government. A second deputation may be necessary later, but for the present it would be wise to try to induce the Local Government Board to put a little more pressure on the local authorities. It is, we are aware, a most delicate and difficult matter to adjust wisely the amount of influence which can be exercised by a central authority like the Local Government Board on bodies which are practically independent. The whole tendency of modern legislation has been to give localities more and more independence in administration. The passage of the great Local Government Act of 1894 has developed and extended this policy. In matters of public health, however, the long-garnered experience of the Local Government Board and the scientific authority which it derives from its permanent medical staff lend a weight to its judgment and advice which local bodies would be wise to follow. They should be encouraged in this course by a more decided expression of opinion on the part of the Local Government Board. The more widely the question is brought before the new district councils now, the less difficult it will be to carry security of tenure hereafter, when the expected amendment of the Public Health Act is undertaken. We calculate that about two out of every three of the present health officers outside London are appointed annually. There is, therefore, very useful work to be done in every district by the members of the profession in bringing the importance of this question to the notice of the urban and rural district councils. Let the profession do its part, and the Association, through its Committee, will be ready to help them to a successful result.

WILLS AND BEQUESTS.—The late Mr. George Charles Benn, of Rugby, who died on October 15th, aged 73, has by his will bequeathed £1,000 to the Northampton Infirmary, £500 to the Birmingham and Midland Counties Eye Hospital, £500 to the Birmingham General Hospital, £500 to the Royal Hospital for Incurables. The testator bequeaths the Boxent Farm of about 145 acres in Northamptonshire to the Northampton Infirmary.

THE GENERAL MEDICAL COUNCIL.

THE November session dragged its weary length over the week, and only concluded on Monday last. Our readers will find a full record of its proceedings elsewhere, so we propose to call attention here only to its more important features. On the whole it was a very dull session, and to the ordinary observer there was, if anything, more than the usual waste of time. This was especially the case over the report of the Examination Committee. That report was before the Council on several days, and occupied no small portion of three sittings, with the result that its recommendations were referred back to the Committee, to be drawn up in a form more suitable for transmission to the licensing authorities. The way of the Council with its reports is curious. They are presented and received, then discussed in committee of the whole Council, usually at considerable length, and then discussed again in the Council on report. The details are thus often debated on two, or even three, occasions, and when this ends in the remission of the report to its Committee, plain men of business are apt to consider the mode of procedure wasteful of time and patience.

In the case before us the report of the Examination Committee, dealing, as it did, with the results of the visitation and inspection of all Final Examinations in the United Kingdom during the last three years, was necessarily an important document. It failed, however, to reach the standard required by the Council. When it has been improved by having its recommendations codified with the former recommendations of the Council, and by the addition of specific references to the authorities which have failed to come up to the recommendations it will become an authoritative and valuable report. The Public Health Committee, on the other hand, made a model report on the examinations in Sanitary Science, which the Council adopted in a small fraction of the time spent over the remitted document.

The comparative barrenness of the session was, however, redeemed by two significant and novel departures. The Council has resolved to lessen the number of portals to the profession, and has determined to prosecute offenders against Section 40 of the Medical Act (1858).

The Apothecaries' Hall in Ireland, till recently, was conjoined with the Irish College of Surgeons, but this examination was reported to the Privy Council last May as "insufficient." Since then the Hall has been unable to form any fresh combination, and consequently applied to the Council to appoint examiners as provided in the Act of 1886, and as was done in the case of the Apothecaries' body in London in 1887, when it was unable to combine. There was a very interesting debate, in which, more *Hibernico*, the Irish bodies were not unanimous on their national concerns. There was also a little want of logic in the position assumed by the majority, who refused the application, inasmuch as they based their refusal to grant examiners, either surgical or general, on the ground that they had found a combined body "insufficient," while the application was preferred for the construction of a new examining body, of which the Council itself would create and control a large portion of the examiners. We admit that we are not sorry to see a step taken at last to lessen the number of portals to the

profession, but as this matter is pretty certain to come before the Privy Council by way of appeal against the extinction of the Apothecaries' Hall in Ireland, it is best not to discuss it further at present.

The other new departure we welcome most heartily. Persons still advertise, often in connection with very objectionable publications, in such a way as to lead the public to regard them as registered practitioners. This illegal assumption of medical titles, the 40th Section of the Act of 1858 was enacted to prevent. The Council has now resolved to prosecute by its own legal advisers such offenders. It has taken many years to arrive at this determination, but it is a case of better late than never. It may be too late to win for the Council that popularity with the profession which it might once have won, but it is not too late to leave the old and beaten track of timidity and impotence, and make use of all and every power which the Act contains to vindicate the profession and protect the public.

THE Lord Rector of Edinburgh University, the Right Hon. the Lord President of the Court of Session, will deliver his inaugural address to his constituents, the undergraduates, on Friday, December 6th.

THE Government of India has ordered that copies of Mr. Hankin's pamphlet, entitled the *Cause and Prevention of Cholera*, shall be issued to all medical officers, with instructions to record the results of any experiments made by them and to communicate the results direct to Mr. Hankin at Agra.

It is gratifying to hear of the further testimony of the usefulness of the Library of the British Medical Association, which is open to all members, and is being daily used by increasing numbers of readers. In his preface to the new work, *Surgical Diseases of Children*, Mr. D'Arcy Power says: "The collection of theses for the Paris M.D. which is being augmented daily at the Library of the British Medical Association has afforded me invaluable assistance, for each contains a valuable bibliography in addition to the original work, which is often important."

ADDENBROOKE'S HOSPITAL.

THE history of the origin of Addenbrooke's, as of so many other hospitals, was, to parody the old definition of a proverb, the needs of many and the munificence of one. It has been retold in a recent number of the *Cambridge Review*. Addenbrooke was a Fellow of Catharine Hall, who, when he died in 1719, left a bequest to found "a small Physical"—that is to say medical—"Hospital for poor people." Some twenty years later a small hospital was built, but funds were wanting to carry it on, and it was not until, in 1766, an Act of Parliament was obtained to make the institution a general hospital, and to give to subscribers of two guineas the privileges of governors, that Addenbrooke's Hospital was able to begin the work which has been carried on to the present with ever-widening scope. In 1865 the hospital was practically rebuilt, and with the additions since made its accommodation has been raised to 153 beds, and it is now one of the best equipped hospitals of its size in the country. As the hospital of the University town which has the largest and best equipped extra-metropolitan medical school in England, Addenbrooke's is a hospital in which the medical profession must take a peculiar interest. Owing to the special constitution of the hospital, fixed by the Act of George III, there is no direct connection between it and the University, but, it is stated in the article in the *Cambridge*

Review, "no difficulty has ever arisen to mar the cordial relations between the hospital authorities and those of the University School of Medicine" throughout the fifty years during which medical students have been admitted for clinical teaching to its wards; yet the want of a connecting link has been felt, and probably the many medical graduates of Cambridge could not find a better mode of showing their gratitude to their Alma Mater than by becoming governors of Addenbrooke's Hospital, which, it would appear, finds some difficulty in meeting all demands upon its pecuniary resources.

THE BATTLE OF THE CLUBS.

LAST week we had the pleasure of recording how, by standing shoulder to shoulder, and frankly appealing to the good judgment of the majority of club members, the Portsmouth Medical Union had won a complete victory against schemes which would have rendered intolerable the position of the medical officers of certain clubs there. This week we publish an extremely encouraging letter from the Honorary Secretary of the Inverness Medical Society relating the steps which have been taken there since the meeting in April last, when resolutions were adopted relating to medical attendance on members of clubs and friendly societies. The medical men in actual practice in Inverness are perfectly unanimous, and it appears that, as has happened in other places, the clubs are now advertising for a medical officer to "several benefit societies." We desire to call the attention of any young practitioner who may be tempted to apply for the appointment to the disadvantages by which it is surrounded. These are sufficiently set forth in Dr. Moir's letter at page 1461. Briefly stated, they are that he will be used to inflict a permanent injury on the profession to which he belongs, that he will be expected to do an immense amount of work, and will be paid a salary on which it will hardly be possible to keep body and soul together. It is honourable to refuse wealth in order to retain independence, but to be a slave and poor is not only degrading but contemptible.

THE TEACHING UNIVERSITY FOR LONDON.

IT must be confessed that the large and important deputation representing all the institutions in London mentioned in the report of the Gresham University met with rather a chilling reception from the Duke of Devonshire on November 28th. Lord Rosebery, last January, was more genial if not more hopeful. He did indeed insist that there was little hope of passing a bill through Parliament for the creation of a Statutory Commission if it were to be met with serious opposition from any quarter in the House of Commons, and urged therefore the necessity for a compromise which would remove the opposition threatened, but personally he seemed to be strongly in favour of the proposed action. The Duke of Devonshire, his successor as Lord President, appears to be equally fearful of the effects of criticism in the House of Commons, and more deeply impressed with the difficulty of conserving the rights of those extern students who now obtain the degrees of the existing University without attendance at any teaching college. Further, he laid great stress on certain "amendments" which had been placed in his hands by those members of the old Annual Committee of Convocation who had been nominated to consult with the Senate on the matter. It should be remembered that this consultation never took place owing to the fact that the large majority of the old Annual Committee were not re-elected but were replaced by others well known to hold opinions favourable to the appointment of a Statutory Commission to frame statutes in general accordance with the report of the Gresham Commission, with power to make such modifications as they might see fit after hearing Convocation and other bodies affected. Practically this is what the deputation to the Duke of Devonshire asked; it is what the Senate desires, and what Convocation in

meeting assembled, the only fashion in which legally it can express an opinion, has on two occasions approved by considerable majorities. The amendments to which the Duke of Devonshire referred appeared to be certain suggestions which five members of the old Annual Committee appointed to meet to consult with the Senate submitted to a Committee of that body. These gentlemen, however, by that time had ceased to represent the Annual Committee, and in fact did not possess any representable quality. The "amendments" themselves appear to deal with matters of detail of such a nature as might properly be urged before the Statutory Commission which it is sought to have appointed. A certain number of members of Convocation, however, appear now to wish to go a good deal further. As will have been seen by a paragraph in the *BRITISH MEDICAL JOURNAL* of November 30th, a meeting of members of Convocation was held on November 29th, and an opinion expressed that any scheme settled by Statutory Commission should afterwards be submitted to Convocation, for its approval or dissent. This was a private meeting, and the views there expressed cannot be accepted as having any authority. The proposal is contrary to the precedents established when it has been found necessary to institute reforms in other universities; and it seems hardly reasonable to expect Parliament to submit the decisions of a Statutory Commission, which is almost tantamount to saying the decisions of Parliament itself, to the veto of the Convocation of the University of London.

EXTENSION OF THE EDINBURGH ROYAL INFIRMARY.

At a meeting of the Extension Committee of the Edinburgh Royal Infirmary held on December 3rd, it was resolved to recommend that the extension operations should at once be proceeded with. By means of the large legacies lately received the debt on the existing buildings has now been paid off, and a balance of £30,000 to £35,000 left on hand. It is known that other funds will soon be received sufficient to bring the amount up to £50,000. Plans by Messrs. Sydney, Mitchell, and Wilson, architects, were submitted at the meeting. These indicate three new pavilions on the site of the old Sick Children's Hospital, and behind it. There will also be a small pavilion for diseases of the skin, with attendant offices, baths, etc., and a much-needed new laundry. All this scheme would cost about £100,000. It is proposed that a first instalment of this, to the cost of £50,000, and to include the laundry, should at once be begun, leaving the rest till funds have been received.

THE RABIES EPIDEMIC.

There can no longer be any doubt that the whole country is about to suffer from another severe epidemic of rabies, and for this the policy of the Board in Whitehall is wholly responsible. The severe outbreaks which during the past twelve months have occurred in various provincial centres, and which the utterly futile system of partial muzzling has been powerless to restrain, have naturally resulted in a spread of the disease over wide areas, and the metropolis is now threatened with a recurrence of the disastrous experiences of the years 1885 and 1886. The direct responsibility for this lamentable outlook rests, as we have again and again pointed out, with the Board of Agriculture, an authority which by its supineness and neglect to exercise the powers entrusted to it by the Legislature merits the severest censure. In January, 1891, a grave protest against the withdrawal of the general muzzling order was made by the Society for the Prevention of Hydrophobia, warning the Department that until a general muzzling order was enforced for twelve months simultaneously throughout Great Britain, the extinction of rabies would be impossible, and that deaths from hydrophobia would inevitably recur. This memorial, which was signed by the Duke of Northumberland as President of the Society, also bore the names of Sir Joseph Lister, Sir Spencer Wells, Professor Victor Horsley, Dr. Ruffer, Dr. Gowers, and Mr.

Ernest Hart, as well as those of Professor Huxley, Professor Tyndall, Professor Ray Lankester, and Mr. Romanes, besides such recognised authorities on canine matters as Mr. Irwin Cox, Dr. Fleming, Mr. Everett Millais, and Mr. Britton Riviere. To this protest Mr. Chaplin, then President of the Board of Agriculture turned a deaf ear, and now the result anticipated has come to pass. Each succeeding Government is afraid to touch the question of general muzzling for fear of encountering the opposition of a section of its political supporters. Rabies might be stamped out of the United Kingdom by the enforcement of a general muzzling order for a sufficiently long period, followed by permanent quarantine regulations, as it has already been stamped out in other countries; and the majority of dog owners and dog breeders are quite as strongly in favour of muzzling as those who have no interest in dogs. But until the epidemic assumes such dimensions as to create a feeling of panic amongst the general public we may expect the official policy to be still one of *non possumus*.

HOUSE SPECULATION AND SANITARY AUTHORITIES.

The Secretary of the Metropolitan House Investment and Agency Company (Limited) has sent to each member of the Islington Vestry, to the vestry clerk, and to the *Islington Gazette* a letter complaining of the expense occasioned to owners of house property in Islington by the manner in which the sanitary department of the vestry are enforcing the powers conferred upon them by the Public Health Act. The letter states that the company owns sixty-eight houses in the parish and collects the rent of fifty-one other houses, making a total of 119 houses, of the aggregate net annual rateable value of £3,500, or thereabouts. "During the period from January 1st, 1891, to the present time," the letter continues, "notices have been served by your sanitary department on no fewer than fifty-three of the above mentioned houses, necessitating in all but two or three cases the entire relaying of the drains and erection of ventilating shafts, etc." The writer observes, "This continuous outlay renders house property in your parish almost worthless"; and he adds, "My directors some time since resolved that no more houses should be purchased in your parish, and notwithstanding the fact that this company has since purchased £50,000 worth of property in London, not a single house has been bought in Islington." Mr. A. E. Harris, the Medical Officer of Health, in forwarding a copy of the letter in question to the Local Government Board, writes: "In every instance the premises were visited, either by reason of the occurrence of an infectious disease or through complaint having been made to me of their insanitary condition." Mr. Harris observes that the document affords a strong argument in favour of Section 108 (c) of the Public Health (London) Act, 1891, which provides that the appointment of a medical officer shall not be for a limited period only; and he says, "I shall fearlessly continue to perform my duties in a manner consonant to the regulations laid down by the Local Government Board for my guidance."

THE TRAINING OF GIRLS.

A STUPID argument has more than one mischief in it; it is not only wasteful and wearisome in itself, but it actually damages the side on which it is urged, in so far as it drives more clear-sighted men to think that there can be nothing to say on the side which uses such arguments. Such we must say with all respect were the feelings with which we read the reports of a discussion on the woman question in the College of Physicians the other day. Stupid worn-out arguments on one side drive opponents to an intolerant forgetfulness of what truths may lie on the side of the "stupid party." The admirable remarks of Dr. Playfair, which we publish elsewhere, serve by their open-mindedness on both sides of the question to steady our minds, side by side with a cordial sympathy with the enlargement and invigoration both of body and mind which the

new life has given to women he does not forget what lies at the bottom of the more reasonable objections to women's work in the world—namely, that she works under certain sexual conditions which she is disposed in her enthusiasm to minimise or ignore. Women will do well to give heed to the wise and generous cautions of Dr. Playfair, and this the more that the sacrifices he imposes are not so very burdensome after all. The ideal state for a woman is to ally herself with a husband of aspirations and culture no less than her own, and to find her peculiar happiness in the blessing of children. Not the least of the gains to be drawn from a more cultivated woman is that they may thus wean men from their more vulgar ideas of money-getting and ostentation, and from their grosser pleasures. Now, while we take a little objection to Dr. Playfair's literal statement that the great sexual function of menstruation dominates a woman's whole existence—an expression which, taken apart from the rest of his article, seems to ignore the psychical side of womanly sexual development—yet we cannot too strongly urge upon women, and those who have charge of girls, to watch and carefully respect the menstrual periods in their occurrence. Some of us were of opinion that by a little courage and habit, and in a higher state of bodily vigour, the menses might be disregarded in regular callings and exercise. We have changed this opinion, and have convinced ourselves that girls and women are unwise in pursuing their exercises, whether of body or brain, at any rate during the first two days of the period. This precaution is economical in the end. Employers of women, in paying lower wages, ought to give some relief in this matter in return; and mistresses of households ought to have some regard to this recurring event in the women under their care. Some women need this consideration more than others.

CONVICTIONS OF SUPPOSITITIOUS SURGEONS.

A CORRESPONDENT has called our attention to paragraphs in the *Clevedon Mercury*, from which it appears that at the last Somerset Quarter Sessions two persons, described as "Surgeon" and "Doctor of Medicine" respectively, were convicted and sentenced to imprisonment. In the one case it is stated that "John Young, 74, Surgeon," was sentenced to three months' imprisonment, with such hard labour as he was capable of performing, for false pretences at Radstock and Midsomer Norton, and for false pretences at Shepton Mallet, under the names of James John Young and John de Courcy Young. In the other case, James Russell, *alias* Francis Victor Devene, 39, Doctor of Medicine, was sentenced to six months' hard labour for false pretences at Stoke-sub-Hamdon and Mudford. We have made inquiries, and find that neither of these persons is or has been upon the *Medical Register*. It would not be too much to expect that the police authorities, in framing indictments and drawing charge sheets, should take the trouble to find out whether such titles as Surgeon or Doctor of Medicine are actually legally possessed by prisoners, so as to prevent the slur being cast upon the medical profession by its appearing in the court records or reports that qualified medical practitioners were convicted and sentenced, when such is not the case. The *Medical Register* is perfectly easy of access to the police, and is in every assize court, so that there can be no excuse for these false descriptions of prisoners.

BELFAST ROYAL HOSPITAL.

THE vacancies created by the lamented death of the late Dr. Ross have been filled up. At a meeting of the life governors and General Committee held upon December 2nd, Dr. Strafford Smith, who has been assistant physician for the last seven years, was unanimously elected staff-physician. To the post vacated by Dr. Strafford Smith, Dr. W. Calwell, who has been registrar to the staff of the hospital for the last two years, was elected by a large majority.

For the post of registrar now vacant, which is in the gift of the staff, a large number of candidates have presented themselves. The post is an onerous and difficult one, but is much coveted as a probable stepping-stone to the staff. The appointment will be made in a few days. Dr. Thomas Houston has been elected extern house-surgeon to the hospital in succession to Dr. Whitaker. The annual meeting of the hospital was recently held. From the report it appeared that 2,255 intern patients, and 22,956 extern patients had been treated during the year. The financial year began with a small balance in favour of the hospital, and closed with a small balance against it. The subscriptions from the working classes show a steady and satisfactory increase, but most other sources of income have fallen off. Some discussions took place at the annual meeting regarding the use of stimulants in the hospital, and it was pointed out that the amount spent under this head was only about $\frac{1}{2}$ d. per day per patient. Extensive improvements are being made in the institution. The operating theatre has been enlarged, refitted, and brought into line with modern requirements. The isolation wards are being rebuilt, and an entirely new mortuary and pathological department are to be provided. The number of students in attendance is almost exactly the same as last year.

PITHECANTHROPUS ERECTUS.

THE discussion at the Anthropological Institute, to which brief reference was made in the *BRITISH MEDICAL JOURNAL* of November 30th, disclosed considerable differences of opinion among the eminent anthropologists who took part in it as to the nearest affinities of the remarkable animal to which the bones discovered by Dr. Dubois belonged. His own opinion of the remains is that they must be regarded as a new family of the primates, occupying an intermediate position between the hominids and the simiids, but in the direct line of ascent to man. He mentioned that while in Germany they were regarded as remains of apes, in Britain there had been a tendency to consider them as human. It may be interesting to add to the particulars contained in the account last week of Dr. Dubois's address in Edinburgh that the bones were found from 12 to 15 metres below the level of the plain, in pliocene and volcanic deposits which have, in consequence of late volcanic eruptions, been rearranged. The mammalian remains consist of several well-known forms of deer, elephants, and other animals similar to those of the pliocene fauna of India, and clearly indicate the epoch to which the strata belongs. These remains are never found as complete skeletons, but as single bones and fragments, on account of the disturbances which have occurred in the strata wherein they are deposited during the process of rearrangement just mentioned. The author described the position in which the remains of *Pithecanthropus* was found and their character. They consist of a calvaria, the under portion of which is unfortunately absent, two upper molar teeth, and a femur. The calvaria and the teeth were found one metre apart, and the femur about 15 metres higher up the stream. Notwithstanding the distance apart at which the bones were found, Dr. Dubois gave reasons why they should be regarded as belonging to the same individual. The calvaria is a very remarkable one, presenting some resemblances to the Neanderthal type of skull but yet very different from it, and approaching more nearly to that of the gibbon, one of the anthropomorphous apes. The frontal region is extremely low and flat, the glabella and supraorbital ridges are enormously developed, as are also the external orbital processes; the parietal and occipital regions are more similar in form to man, but there is present a distinct ridge extending from the superior curved line of the occiput to the temporal region, which, while very characteristically developed in the apes, is entirely absent in man. In its general form the calvaria is dolichocephalic. The cranial capacity is only about 1,000 cubic centimetres, a size so small as never to be met with in

man, except in some of the lowest races of savages or microcephalic idiots. The last molar tooth is the more characteristic of the two, the other being considerably worn down on the grinding surface, while the former is but little worn. It is remarkable for the large size of its crown and roots. The characters of the grinding surface, though not far removed from those of the corresponding tooth in man, does not entirely agree with it, nor are they exactly the same as in either the gibbon or the orang. In general form the femur is remarkably human-like, but when examined closely as regards the characters of the lower and posterior surface shows considerable divergence, as do also the inferior aspect of the condyles; it also presents a curious and rare pathological condition in that there is a large osseous mass present in the upper third of the shaft, the result of ossification of the tendinous insertions of the muscles attached to the upper and inner aspect of the bone.

THE SANITARY RESPONSIBILITIES OF WATERING PLACES.

It is right and proper that a health resort should be sensitive on the score of its sanitary reputation, and should spare no effort to find out and amend the weak points, if any there be, of the remediable kind. It is legitimate, also, to advertise its bracing or balmy or equable climate, its abundant sunshine and little rain, its pure air and water and soil, its low death-rate, and phenomenal freedom from zymotic diseases, and so on, always assuming that the statements made are reasonably accurate and not "selected" to such an extent as to be misleading. To a certain extent, which it would be difficult to define, it is permissible to maintain a discreet silence upon less favourable points; but the one thing to be avoided, next to neglect of sanitation, is a reputation for disregard of ascertained defects and for concealment of unpleasant facts and accidents. Unless the reporter of the *Eastern Evening News* misrepresents him, the Chairman of the Sanitary Committee of the Lowestoft Town Council holds peculiar views with regard to the real interests of the town and the responsibilities of the medical officer of health. At a recent meeting, it appears, he took exception to the publicity given to the health officer's report, and pretty plainly intimated his opinion that some degree of censorship was necessary. The report in question recorded a high death-rate for the month of October, largely due to the mortality from measles, whooping-cough, and diarrhoea, and, to a less extent, diphtheria. Reference was also made to some overcrowding of lodging-houses, and to the state of the middens. Which of these items the Chairman wished to suppress is not made quite clear, but he proceeded to pit his own opinion against that of the medical officer of health in the matter of the middens, contending, apparently, that the real contributory causes of the epidemics were to be found in the neglect to close schools at the proper time, and in the foul state of the public sewers due to the absence of proper means of ventilation and flushing. It is far from obvious in what way the fair fame of the town was supposed to be vindicated by the enumeration of these additional sins of omission on the part of the sanitary authority, especially in the absence of any promise of immediate rectification. Nothing could be less reassuring to the ratepayers or to intending visitors than to find the Chairman of the Sanitary Committee challenging the official report of the medical officer of health, unless it be the discovery that if the former could have his way, matters seriously affecting the public health should be kept from the public knowledge. It is not at all probable that either sewers or middens had much to do with measles or whooping-cough, whatever share they may have had in the causation of diarrhoea or diphtheria. Closure of some or all of the schools might or might not have been judicious; if it was not done, we may assume that the medical officer of health, with knowledge of the circumstances, did not think it neces-

sary. It is for him, as the responsible professional adviser of the corporation, to judge of this, and it is his plain duty to report upon all the facts. This report is an official and professional one, not subject to revision by any second person, or by the committee or council to whom it is addressed. It does not appear that any other speaker expressed similar views, and it is to be hoped that the Chairman of the Sanitary Committee will take an early opportunity of disclaiming the interpretation to which his published remarks obviously lend themselves.

SAFETY IN OIL LAMPS.

THE enormous increase which is everywhere apparent in the use of paraffin, both for heating and lighting purposes, makes it desirable to draw attention to the conditions of safety in an oil lamp. Even during the two summer quarters of this year, that is from April to September, more than two hundred lamp accidents were reported in London alone, besides an unknown number which were never heard of from their not having been attended with either fire or loss of life. For some years past Mr. Alfred Spencer, of the Public Control Department of the London County Council, has carefully investigated the origin of all the cases of accident from lamps which have come to his knowledge, and has experimented with the various types of so-called safety lamps with the object of determining how far they afford security. It is expected that the report which he will shortly issue on the subject will lead to definite steps being taken to prevent the sale of lamps which, from their construction, are known to be dangerous to those who use them. All serious casualties from the use of lamps are caused by the scattering and ignition of the oil. It therefore follows that for the sake of ensuring safety lamps must be so constructed that they shall not explode, that they shall not permit any considerable escape of oil when they are overturned, and that they shall be so strongly made as not to be liable to break under the strain of any accident which is likely to befall them. A metal reservoir may be so badly constructed and fragile as to be dangerous. The investigations of Mr. Spencer have led him to the conclusion that in at least 25 per cent. of the cases of accident brought to his notice the cause has been explosion of the lamp. The arrangements of the burner and the wick must be such as to prevent any communication between the flame and the oil reservoir. There are three principal ways in which this communication may take place: (1) from the wick not completely filling the wick tube; (2) from the air vent opening into the burner or into the wick tube; (3) from some other opening, as, for example, for the accommodation of the ratchet mechanism existing between the burner and the reservoir. The last two are obvious errors of construction. In regard to the first, the best protection is the presence of a long wick tube by means of which the wick is carried direct nearly to the bottom of the oil, so that even if flame were to strike down the burner, from the wick being turned too low, or from the lamp being exposed to a current of air, it would be trapped off from the explosive vapour by the oil in the reservoir. It would appear, then, that the old recommendations which the County Council made in a memorandum issued some time ago are still held to remain good, and to be sufficient if enforced practically to ensure safety in the use of paraffin as an illuminant. The three chief of these were that the reservoir should be of metal, strongly made; that there should be a wick tube descending nearly to the bottom of the oil; and that the burner should be firmly screwed into the body of the lamp.

THE ASHANTI EXPEDITION.

IN the arrangements for medical supplies provision has been made for 30,000 cases of sickness. The term "cases of sickness" refers to daily moras, and embraces a man placed on the sick list for treatment one day and taken off the next. In the former Ashanti war there were 21 deaths

from disease and loss in action, with 2,567 officers and men of the European force under Sir Garnet (now Lord) Wolsley. After leaving the country there was a mortality of 3 per cent. on the strength disembarked. Tents on this side of Prahu, it is thought, will not be necessary, as huts can be utilised for housing the troops at the various rest camps. Beyond Prahu *tentes d'abri* will, it is stated, probably be employed. The daily ration scale is set down as $\frac{1}{2}$ lb. each of fresh meat and bread or biscuit; if preserved meat is used, 1 lb.; preserved potatoes, 1 oz.; sugar, 3 oz.; tea, $\frac{1}{2}$ oz.; cocoa paste, 1 oz.; dried onions or compressed vegetables, 1 oz.; salt, $\frac{1}{2}$ oz.; pepper, $\frac{1}{4}$ oz. In the matter of bread and meat, the scale is the same as in the last war, but the tea ration is $\frac{1}{2}$ oz. less, the cocoa paste being additional. Surgeon-Colonel Taylor, principal medical officer of the expeditionary force, has visited Aldershot and inspected the whole of the officers, non-commissioned officers, and men of the Medical Staff Corps who are proceeding on service to the West Coast of Africa. The bearer company drilled in good style. All ranks paraded in service uniform and equipments, and looked fit for the work they will be called on to perform. Among the stores which the *Loanda* carried when she left Liverpool on Saturday, November 30th, for the Gold Coast, were a number of Pasteur filters for the provision of pure water for the troops. These filters had previously been tested by Surgeon-Colonel Taylor and Surgeon-Lieutenant Pratt, and a detachment of the men has been instructed in their method of working. They are capable of providing altogether 6,000 gallons of germ-free water daily. Filters of a similar kind are to be fitted to the hospital ship *Coromandel*.

THE FRENCH CRUSADE AGAINST ALCOHOLISM.

We have already recorded the systematic efforts of the Minister of Public Instruction to combat alcoholism through the schools in France. In the direction of preventive and repressive legislation the medical profession is largely represented in the league against alcoholism, and in a special committee which has been elected to formulate a suitable measure. Among the members are Drs. Semelaigne, Philibert, Bergeron, Lannelongue, Fleury, Ravarin, Guillemet, Bianchi, Ledain, Motet, Magnan, and Cheysson. Deputy Siegfried, at the last meeting, called attention to the enormous increase of alcoholism in France. In 1890 the consumption was 1.12 litre of pure alcohol per head per year; in 1894 it was 4.04 litres. In 1890 there was one shop for the sale of drink for every 113 inhabitants; in 1894 one for every 84. The results of this increased consumption were more exemptions from military service on account of physical inaptitude and mental alienation. On the other hand, the alcoholic consumption had diminished by one-half in Sweden, and in England from 2.86 litres per head per year in 1882 to 2.70 litres in 1892.

THE SICK POOR IN IRISH WORKHOUSES:

BALLYSHANNON: THE TASK OF HERCULES.

Those who have been saddened by previous reports of the condition of the sick poor in Irish workhouses will be cheered by our Commissioner's account of Ballyshannon Union Infirmary. Eighteen months before the visit was paid a community of Roman Catholic nuns had taken over the management of the workhouse. The Superior, clearly a woman of rare capacity and tact, took on herself the office of matron, and with the willing co-operation of the medical officer, the guardians, and the master. She has in that short time worked wonders. The structure is the same, the sanitary arrangements were at the time of the visit of the old primitive kind, but order, efficiency, and above all, humanity, now prevail in the management. Pauper nursing is swept away, with its attendant evils, neglect, and blackmail; a trained night nurse is appointed; the epileptics and idiots are nursed in the infirmary wards, instead of being relegated

to dark ill-ventilated cells; in short, though much remains to be done in the way of structural improvement, all that care and attention can devise is done to alleviate the lot—at best a dreary one—of the sick and aged pauper. And the moral of it is that capacity and self-devotion are not to be thwarted by the worst system ever invented; men, not measures, determine for good or ill the fate of those that lie under their authority. Yet it takes a Hercules to cleanse an Augean stable—average humanity shrinks from the task. The present system depresses the average official, and allows the bad to go undetected and unpunished. It should be possible so to reform it that the average official is kept up to the mark, and the bad eliminated. Such work as that of the good nuns at Ballyshannon brings us nearer the day of a general reform in the administration of the Poor Law.

MASSAGE INSTITUTIONS.

THE recent charge against the proprietors of a bogus massage institution of obtaining from ladies by false pretences various sums of money, amounting in all to £300, has called attention once more to the existence of these pernicious establishments. The "astounding revelations" of the last few weeks, although they may have excited the surprise of the general public, have presented no aspect of novelty to the readers of the *BRITISH MEDICAL JOURNAL*, the whole subject having been fully dealt with in these pages more than a year ago. That these massage shops still exist in large numbers, not only in London, but in many provincial towns, is an undoubted fact; that most of them simply serve as a cloak for immoral practices of the most revolting description is equally well established. It is true that their advertisements are no longer accepted by the fashionable morning paper in which for so many months, in spite of repeated protests, they formed so prominent a feature, but little by little they have crept into other publications, notably those devoted to financial matters and circulating amongst members of the Stock Exchange. From advertisements before us we gather that in some of the establishments, which are described as being fitted up with every luxury, the proprietress is assisted by from four to eight qualified young lady assistants, by whom visitors are received from 10 till 8. The latest novelty is the custom of advertising these places by means of sandwich men, who, during the busiest hours of the day are very much in evidence in some of the West End thoroughfares. At night transparencies, lighted by electricity, are substituted; so that there is very little probability of the stranger in London failing to find the accommodation which is so prominently brought under his notice. Stories of blackmailing are common enough, but of these we say little, for the victims are but little likely to air their grievances in a court of law.

TASMANIA AS A HEALTH RESORT.

It is curious, considering the steady stream of invalids which has for so many years set towards Australia, that, comparatively speaking, so few should have turned towards the neighbouring island of Tasmania. Probably the old belief that warmth was an essential in the treatment of diseases of the chest has had something to do with this, and so it has happened that while phthisical patients have accumulated in the crowded cities of Australia, the breezy uplands of Tasmania have to a large extent been neglected. It is not of uplands, however, that we would now speak, but rather of a seaside resort standing on a large bay on the western side of the island, to the advantages of which our attention has recently been drawn. The town of Swansea is well situated on Oyster Bay, having opposite to it, but at a dozen miles distance, the fine headland of Freycinet Peninsula, on which is Mount Freycinet, a timber-clothed hill 2,014 feet high. The town is said to be well laid out, with wide streets and substantial buildings, and the scenery around is described as being of a most beautiful character.

The climate of Tasmania is of a much more temperate character than that of Australia; in fact, most English fruits grow there to great perfection. The difference between the mean temperature of summer and winter is 15 degrees. Snow is very rarely seen except on the mountains; the average rainfall for the island may be put down as something like that of England, but the amount of sunshine recorded in Tasmania is very materially in excess of that of Great Britain. The air is drier, the atmosphere clearer, and the extremes of heat and cold less trying than in the mother country. Here we seem to have the elements of a climate which ought to be useful to many who, if not already invalids, require a change of scene and an escape from the fogs of English winters. For such people it is undoubtedly a great advantage, if they wish to return shortly to their native country, not to become too much habituated to tropical heat, otherwise the return to a northern climate is apt to lead to a renewal of the very mischief they are most anxious to escape from.

FRIENDLY SOCIETIES' MEDICAL AID ASSOCIATIONS.

A correspondent sends us his experience as medical officer to one of these associations. He says every member paid 3s. a year, their wives 3s., and each child up to the age of 18 years 1s.; he was expected to visit within seven miles of the dispensary, and to attend during the year many confinements at the rate of 7s. for each one. From his visiting book it would appear that during one week he made as many as 230 visits. If many of these were at a distance of seven miles from the dispensary, it is to be wondered how he got through the work. "There were," he writes, "three sittings at the dispensary daily. One medical officer sat twice and the other once, alternately, and members out of work were appointed to follow us 'to show us the way.' I learnt there that it is to be servant of a working man, and God forbid that my professional brethren should have similar experience. It was really hard labour. In addition to this we were expected to attend about 200 cases each of confinements yearly at 7s. each. The members paid 10s. 6d., and 3s. 6d. was deducted by the Association. My health soon began to give way, and I sent in my resignation, and was reminded that they expected three months' notice according to agreement. While I was deliberating what to do I heard them discussing eight hours a day for working men, and I took advantage of what I heard to inform them that I intended setting them an example by not working more than eight hours a day, and I kept my word. The result was that I was allowed to leave in a week." It is not surprising that our correspondent soon got tired of his post, and the account he gives of what he had to put up with as the badly paid servant of an Association of this kind shows pointedly the degradation incurred by medical men in accepting such appointments. Surely the position of assistant to a brother practitioner is far preferable, even granting that some principals are not all that could be desired, to such a situation as is here described. The young practitioner desiring to be independent looks down on his position as an assistant, and often thoughtlessly accepts one of these posts, only to find out, too late, that far from gaining the wished for independence he is a greater slave than ever, and in return for a slightly increased pecuniary remuneration his work and responsibility are enormously increased.

MEDICAL CERTIFICATES FOR BOARD SCHOOL CHILDREN.

The annual report of the School Attendance Committee was presented to the London School Board last week, and the attention there drawn to the matter of medical certificates has led to a correspondence in the *Times* in which Dr. J. G. Fowler has taken an able and useful part. It must be understood that the School Board has no power to demand these certificates either from the medical man or from the parent,

the whole duty of discovering the reason for a child's absence, and of prosecuting the parent in case of this proving insufficient, being thrown on the Board, who employ paid officers for the purpose. The sole object of a medical man in giving a certificate in regard to any child who may be under his care is to prevent the child being sent to school when unfit; in other words to protect the parent from possible prosecution for not enforcing his child's attendance. If, then, the certificate is not to be accepted as sufficient for this purpose, there is no longer any excuse or reason for giving it; in fact, if it is not recognized by the officials it is only likely to lead the parent into difficulties. It is needless to insist upon the enormous assistance which proper medical certificates are to the School Board officials in the performance of their very important duties, or upon the fact that this help has hitherto been given by our profession. We believe that medical men are perfectly willing to continue to give this help so long as they receive an assurance that their certificates will be accepted for the purpose for which they are given, namely, as a means of relieving the parent from the obligation of sending the child to school. It has been imagined by some that the medical certificate is a protection to the parent as against the School Board when a case comes before the magistrate. No doubt it may happen sometimes that a magistrate who is greatly worried by innumerable School Board summonses may, almost thankfully, catch at a medical certificate as a reason for dismissing a case; but in no case which was seriously contested would such a certificate be accepted in a court of law. All evidence would have to be sworn and be open to cross-examination. Recognition of this fact puts the medical certificate in its true light. It is purely an assistance to the School Board officials in discovering which cases they ought to prosecute. That is to say its only use is to help these officials in doing work which, with or without such assistance, they are bound to perform. Under these circumstances the appointment of special medical men by the Board to decide in which cases these certificates shall be accepted, and in which refused, is a most ungracious act. We quite sympathize with the School Board in the difficulties they meet with in enforcing attendance. Their officials are overwhelmed every day with excuses and with certificates signed by unqualified practitioners or by chemists, herbalists, and quacks of all sorts. There can be no doubt that properly appointed medical officers should be employed to look through all the certificates received, and to investigate those which are not signed by duly qualified medical men. Such certificates, however, as are properly signed by legally qualified persons should be accepted without cavil. If people are found signing false certificates, let them be prosecuted; let it be demonstrated both to the profession and to the public that a certificate is not a mere form, but a document to be carefully considered before it is signed; but when once a certificate is honestly signed, let it be recognized as a protection from what the public still persists in calling "the bullying of the School Board officers."

MUSCÆ VOLITANTES.

FOLLOWING the example set by Dr. Gowers in the Bowman Lecture of the present year in studying one set of subjective visual sensations, Dr. George M. Gould, of Philadelphia, in a recent number of the *Medical News*, gives us a description of muscæ volitantes, with a minute description of his own muscæ and of their behaviour under varying physiological states of the eye, and then proceeds to deduce some laws governing the phenomena of muscæ, and their bearing on the economy of the eye. Muscæ are either peripheral, originating in the globe including the optic nerve, or central, originating in the cerebral cortex, or a combination of the two. He suggests the use of the word "phosæ" for light sensations of whatever kind or colour of

a positive nature, and "aphoses" for absences or interruptions of light sensations, such as scotomata or shadows. Speaking of peripheraphoses, the subdivision under which ordinary muscle volitantes come, the author concludes that the fluid in which these bodies float is contained in a chamber situated just behind the lens, which he calls the *aquo-vitreous* chamber; the constant downward movement of the muscle, when seen subjectively, locates this chamber in front of the vertical equator of the eye. The *aquo-vitreous* chamber plays the important part in the nutrition of the eye of acting as a drainage chamber to the vitreous body for the excretion of the *debris* of vitreous katabolic change; the fluid contained in it also acts as a lubricant to the movements of accommodation in equalising and distributing pressure. Further, the author thinks it not unreasonable to suppose that pathological conditions in the fluid may originate pathological conditions in the lens and disturbances in its nutrition, and may be an important factor in the etiology of cataract. Other pathological conditions of this chamber and its contents may lead to a clogging of the sieve of the lens ligament, and so act as the ultimate cause of glaucoma. Myotics like eserine and pilocarpin increase glandular, osmotic, and secretory activity, while mydriatics correspondingly lessen these processes; although an increase in the amount of *aquo-vitreous* fluid would seem to increase intraocular pressure, it would also lessen its viscosity, and reduce the clogging of the filtration membrane of the ligament, and consequently the intraocular tension. The author is of opinion that no one has given a satisfactory reason for the uncertain action of iridectomy in curing glaucoma; according to the theory here proposed removal of a portion of the iris only acts by increasing the porosity of the filtering membrane, but it is not suggested how this is brought about. The author admits that his theory has a very small basis of facts to support it. Before accepting it as a working hypothesis some anatomical proof of the existence of the *aquo-vitreous* chamber is required; with modern histological methods by the making of frozen sections of recently excised eyes, or of eyes hardened in formol, such a chamber should be capable of easy demonstration if it exists. Further, by the researches of Priestley Smith and Treacher Collins our knowledge of glaucoma has been so far advanced that we are able to explain some of the phenomena of the disease, such as the occasional failure of iridectomy, without recourse to a somewhat fanciful theory.

PROFESSIONAL "HOSTELS."

A CORRESPONDENT who protested in the *BRITISH MEDICAL JOURNAL* some time ago against the principle involved in the establishment of the Clergy Hostel, has written again to draw attention to the completeness with which this quasi-charitable scheme has been carried out. We are disposed very much to sympathise with our correspondent's view, that the establishment of this hostel is a bad precedent. It is not so much, as we view the matter, that the medical profession would be indisposed to render freely any necessary assistance to the poorer clergy of all denominations who may be incapacitated by illness, for the amount of such free service is already so considerable that a little more or less can, it might be urged, make little difference. Rather is the scheme to be objected to as a precedent which may be followed in the case of other professions. Already we see it reported that an actors' hostel has been started. The whole question of the provision which ought to be made for the medical and surgical needs of the poorer members of the professional classes is one which appears to stand very much in need of careful and dispassionate investigation by the medical profession. Such persons are not fit subjects for free treatment in the ordinary hospitals, and their admission to these hospitals as paying patients at low rates opens the door to many abuses. On the other hand, they cannot

afford, in many cases, to pay the high charges commonly charged in nursing homes, and living, as many of them do, in lodgings, it is almost impossible for them to go through a long illness, or undergo a serious operation, except in some public or quasi-public and semi-charitable institution. As it is, one of two things commonly happens: either they go into a nursing home, and the physician or surgeon gets nothing; or they go into a general hospital and are maintained and treated gratuitously, or at a rate of payment which leaves the charity out of pocket.

KISMET P

THE letters which have lately appeared in one of our daily contemporaries upon the infectious nature of measles shows that the public is at last awakening to the fact that the exanthemata are preventable diseases. It was thought—and that not so very long ago—that a child's upbringing was not complete until he had passed through an attack of scarlet fever, measles, and whooping-cough. He was therefore allowed to contract these and kindred diseases by sending him to associate with some friend who was known to be passing through an attack. Wiser counsels prevailed with increasing knowledge, and the necessity for prompt and complete isolation is now recognised in all except the most benighted parts of the country. Few can read with dry eyes those pathetic extracts from Catherine Tait's narrative of her dreadful experiences in the Deanery at Carlisle, yet no medical man of to-day can read them without thinking what grief would have been spared if a rigid isolation had been insisted upon from the time the first child sickened. The children were rapidly born to a highly intellectual father and a fragile mother. They had moved from a comparatively healthy home at Rugby to the old and insanitary lodgings appropriated to the Dean at Carlisle. Chatty, the third child, was attacked with scarlet fever, which soon proved to be of a most malignant type, yet the other children were merely sent to the far end of the house, whilst the mother, who was in constant attendance upon her child, and was nursing the youngest baby, daily saw the other children and talked with them. Chatty died, and upon the day of her funeral Susan, the sixth child, sickened of the same disease. The other children remained at home, and there was still free intercourse between them and the attendants in the sick room. The children, indeed, were eventually removed to a house opposite the Deanery, and four days after Susan's death Frances, the fifth daughter, became ill, and she died five days later, yet still there was no interruption to the converse between the house of sickness and the children who had been removed from it. Catty, the eldest daughter, was stricken down on the day Frances died, and whilst she was ill May, the second child, sickened. By this time the children themselves had taken alarm, for May's first request when she felt herself ill was, "Keep Cranford away from me; do not let him come near me." Her request was fortunately complied with, and the boy was removed to a distance from the deadly neighbourhood and from all its distressing surroundings. He indeed escaped with his infant sister, but there still remain the graves containing five little coffins to mark the agony of Easter, 1856. It is clear that these five children, like so many of the fairest and most precocious, lacked that toxin-destroying mechanism which might have reduced the poisonous effects of the infection. The importance of disinfection and of separation from the surroundings was then unknown, and as one child after the other sickened they were taken into the chamber of death until the first child died less from scarlet fever than from the attack of erysipelas which succeeded it. Yet nothing that skill or money would obtain was omitted; the best advice was forthcoming. Sir Robert Christison came from Edinburgh, Dr. Goodfellow from London; tidings from the Deanery were breathlessly awaited throughout England, but preventive medicine was still in its infancy.

GENERAL COUNCIL

OF

MEDICAL EDUCATION AND REGISTRATION.

WINTER SESSION, 1895.

Thursday, November 22nd.

Sir RICHARD QUAIN, President, Bart., in the Chair.

(Continued from page 1334.)

REPORT OF THE EXAMINATION COMMITTEE.

The Council in Committee proceeded with the discussion of the specific recommendations by the Examination Committee in regard to the results of visitation and inspection of the Final Examinations in Medicine, Surgery, and Midwifery of all the licensing bodies.

The third recommendation was moved by Sir DYCE DUCKWORTH, and seconded by Mr. BRYANT, as follows:

That in all the written examinations of the different bodies the questions in each subject should be submitted to the whole of the examiners in that subject before they can be set at any examination.

This was agreed to.

Moved by Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, and agreed to:

That candidates in all their examination work should be carefully supervised.

Sir DYCE DUCKWORTH moved:

That at least half an hour should be allowed for a candidate to answer each question in the papers on Medicine, Surgery, and Midwifery.

He said that evidence had come before the Committee that in some cases candidates had a great many questions to answer, and it was quite impossible for them to do the work properly in the allotted time. The recommendation as proposed would be a sufficient safeguard against that.

Mr. BRYANT seconded the motion.

Mr. TEALE said that some examiners might wish to give a larger number of questions, each of which could be answered in a shorter time than half an hour.

Mr. BRIDGES-CARTER reminded the Council that the suggestion embodied in the recommendation was founded upon absolute reports which they had had before them, and upon statements contained in those reports as to the time allowed for questions, examples being given. They had found instances in which questions were of such a character that they could not be well answered in the time allotted, and they felt that the recommendation would have a twofold beneficial influence—in the first place it would secure to the candidate sufficient time in which to do justice to his knowledge of the subject, and, in the second, it would tend to some extent to guide the examiner as to the character of the questions which should be put, preventing examiners from putting all-embracing questions, and confining them to questions which admitted of a full answer within the specified time.

Dr. FERRIER thought that a few questions did not test a student thoroughly, and suggested that it should be recommended that the examinations in Medicine, Surgery, and Midwifery should each occupy three hours. He moved as an amendment:

That at least three hours be allowed to a candidate to answer the written examinations in Medicine, Surgery, and Midwifery, leaving the details to the examining bodies.

Dr. LUSH seconded the amendment.

Mr. BRYANT suggested that the recommendation should be altered to read:

That an average of at least half an hour should be allowed for a candidate to answer each question in the papers on Medicine, Surgery, and Midwifery.

as that in a paper of, say, six questions, a man might answer one in twenty minutes, another in three quarters of an hour, and so on. In some of the examinations eight or ten questions were put and less than ten minutes allowed for each answer, so that it was absolutely impossible to obtain any thing but perfunctory answers and a bad paper.

Sir DYCE DUCKWORTH agreed to the suggested amendment of Mr. Bryant, which was put to the Council and carried.

Sir DYCE DUCKWORTH moved and Mr. BRYANT seconded: That no candidate should be orally examined in any subject or part of a subject except in the presence of two examiners.

Dr. PHILIPSON suggested the addition of the words "or one examiner and one assessor."

The REGISTRAR pointed out that an assessor was included in the word "examiner."

The resolution was agreed to.

Moved by Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, and agreed to:

That the clinical examinations in Medicine and Surgery should be conducted under the personal surveillance of two examiners.

Sir DYCE DUCKWORTH moved and Mr. BRYANT seconded:

That the Final Examination should include the examination of secretions, the testing of urine, clinical microscopy, and prescription writing, and that there should be always an oral examination in both medicine and surgery, which should include the recognition of pathological specimens.

This was carried.

On the motion of Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, it was agreed:

That at every Final Examination there should be a practical examination in Pathology, macroscopic and microscopic, unless this has been included in the examination immediately preceding the Final Examination.

Sir DYCE DUCKWORTH moved, and Mr. BRYANT seconded:

That the examination in Midwifery, Forensic Medicine, and Hygiene should be made as practical as possible.

Mr. TEALE, although not objecting to the principle, thought that an examination in Midwifery was almost an impossibility. Was it possible to bring a number of men into a lying-in room and ask them one after another to examine a woman?

Mr. BRYANT said it was never the thought of the Committee that a midwifery examination should be conducted as Mr. Teale had suggested, but there were such things as phantoms, and a great deal was to be learned by their use.

Mr. TEALE asked what was meant by an examination in Hygiene.

Sir DYCE DUCKWORTH said that there was one examining Board in the three kingdoms which did carry out practical clinical midwifery, but the Committee fully realized that it was quite impossible to carry out the system, most Boards refusing, but in the course of examining the reports of the inspector they found that the examination in Midwifery had been by no means practical, no attempts having been made by means of the phantom to put practical questions to the candidates. With respect to the subject of hygiene, it was possible the Committee had a little overstepped the actual requirements, and since these recommendations were drawn up he would remind the Council that the whole subject of public health had been transferred to another committee under the excellent chairmanship of Dr. Thorne Thorne; therefore it might be advisable that the words "and hygiene" should be expunged from the recommendation, so that it should read: "That the examination in Midwifery and Forensic Medicine should be made as practical as possible." It was hardly possible to carry out any practical examination in hygiene.

Dr. THORNE (THORNE) concurred in Sir DYCE DUCKWORTH's suggestion.

Dr. RUSSELL thought it was of the highest importance that a practitioner should be able to detect defects in waterclosets and other subjects connected with hygiene.

The recommendation as amended, omitting the word "hygiene," was agreed to.

Moved by Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, and agreed to:

That whatever may be the system of marking, the percentage for a pass (50 per cent.) in each division of a subject, should be uniform to all the Boards, and in accordance with previous recommendations of the Council, and that the marks given on the written examination ought not, as is the case with some Boards, to override those given at the oral or clinical examinations.

Sir DYCE DUCKWORTH moved, and Mr. BRYANT seconded:

That marks given in any part of an examination should be given on the merits of that part alone, and not be subject to future revision unless for the correction of a manifest error.

This was carried.

Sir DYCE DUCKWORTH moved, and Mr. BRYANT seconded:

That the former recommendation of the Council that knowledge of one subject should not be allowed to compensate for ignorance in others, should be more carefully regarded by some of the examining bodies.

Dr. McVAIL thought that the bodies referred to should be specified. It was a charge, and charges should be made openly, public interest requiring it.

Sir WALTER FOSTER thought they had been proceeding on wrong lines. The best course they could have adopted would have been to have taken all the reports of the examiners and called out all the specified charges of negligence or inefficiency with regard to the examinations; then they should have passed directions that each body should be called to order for its omissions or neglect in its examinations, and lastly have informed the other bodies what they had done with the offending bodies. They would have got some result in that case, and would also have avoided sending mere trulams down to intelligent men as the directions of the Council.

Dr. HERON WATSON thought that the matter would properly come up when the report came before the Council, not while they were in Committee.

The motion was carried.

Moved by Sir DYCE DUCKWORTH, seconded by Mr. BRYANT, and agreed to:

That as the art of examining is only to be acquired by practice, it is desirable that an examiner should be re-elected, where practicable, for at least five consecutive years, particularly for the final examinations.

Dr. McVAIL moved and Mr. WHEELHOUSE seconded:

That the following recommendation be adopted by the Council in Committee: That the clinical examinations in Medicine and Surgery should be held in hospitals wherever that may be possible.

This was agreed to.

The Council then adjourned.

Friday, November 29th.

Sir RICHARD QUAIN, Bart., President, in the Chair.

BRITISH DENTAL ASSISTANTS' ASSOCIATION.

The PRESIDENT read the following letter from the British Dental Assistants' Association: "Sir,—A deputation will wait upon you to-morrow (Friday) in reference to my petition and others, at 1.45 p.m., at the Royal College of Physicians."

The question was considered *in camera*, and the following resolution was passed:

That the Council has already fully considered the question on which the British Dental Assistants' Association wishes to send a deputation to the Council; and not being prepared to depart from the decision of May 29th, 1891, cannot receive a deputation on the subject.

THE APPLICATION FROM THE APOTHECARIES' HALL, IRELAND.

The Council then proceeded to the adjourned consideration of the application of the Apothecaries' Hall, Ireland, for the appointment of assistant examiners in surgery.

Dr. CHARLES MOORE said that the corporation of the Apothecaries' Hall was accomplished by the Legislature to meet the needs of the masses of the Irish population by providing a general practitioner more than twenty years before that of the popular sister institution in this country, and for the protection of the public at large against spurious and injurious drugs, and its staff was even now called upon by the Government to decide on the quality of the water and other food of doubtful qualities. The Hall had encountered difficulties at times in carrying out certain parts of its examinations. Many candidates for the Hall licence were unable to pay the comparatively large examination fees required by other bodies. He felt much indebted to independent members of the Council for their testimony to the high character of the alumni of the Apothecaries' Hall, and he was authorized by the Governor and Council of the Hall to give the Council assurance that they should spare no expense, and would use their best endeavours to carry out a thorough examination, and to ensure the respectability of everyone who took the Hall licence. They had carried out to the utmost any amendments which had been recommended to them, and if the Council advised them further it was their determination to carry out that advice. He moved:

That the petition of the Apothecaries' Hall, Ireland, be granted.

Dr. PHILIPSON seconded the motion.

Sir JOHN BANKS supported the prayer of the memorial. The Apothecaries' Hall, Ireland, took the place of what in England were called general practitioners. They were needed by the poorer class who could not pay the ordinary fees of physicians and surgeons, but were still able to get medicines from the apothecary. He knew from experience that that class of practitioner was highly respectable and had done its work well in the past; they were men of very high reputation and character, and many held highly respectable degrees.
